None of the mines of the Pacific Coast suffered from a movement of rock. A day after the earthquake we wrote to the superintendents of a dozen representative mines asking whether they had observed any effect underground. The replies agree in a distinct negative. In the foot-hill region of the Sierra Nevada, the shock was felt only slightly even by those on the surface, while in the mines all was as usual, the occurrence passing unnoticed. At the Great Eastern quicksilver mine near Guerneville, three men were killed by a falling mass of rock that was loosened in the shaft and this accident occurred at the moment of the earthquake, but it has no bearing on the matter. The slight tremor precipitated a loose piece of rock that probably was about to fall and would have fallen a little later, in any event. At the time of the San Francisco disaster, an Associated Press telegram from Houghton, Michigan, announced that the earthquake had caused a collapse of ground in the Quincy copper mine, killing two miners. This also has no connection with the San Francisco earthquake, or any other such phenomenon. The copper mines of the Lake Superior region, more especially those having a large area of excavated ground, are subject to a sudden collapse of stopes, producing shocks that are felt keenly at surface. They are termed 'air-blasts', because they are accompanied by a violent expulsion of the air displaced by the falling rock-walls, producing reverberations similar in a way to those that follow a dynamite explosion. The causes of them were discussed in these columns not long ago and we can only repeat that they have no connection with earthquakes. All the evidence goes to show that as regards earth tremors, the miner is safer underground than the people in the city.

Earthquake Lines.

Written for the MINING AND SCIENTIFIC PRESS by W. H. STORMS.

California geologists have long since agreed that the frequent earthquake shocks felt in this State have their origin along well-defined lines, some of which are known. Of these several lines of weakness and disturbance, the most important and interesting is that which passes in the vicinity of San Francisco.

Mountain ranges, broadly speaking, are built, either by the outpouring of volcanoes; the carving out by erosion of elevated plateaus, or by the slow, long-continued uplift of elongated rock masses due to the interior shrinkage of the earth, which causes wrinkles, as it were, to form on the surface. The first may be violent and spasmodic, like the recent eruption of Vesuvius, or the demonstration may be quiet, unaccompanied by explosion or destructive earthquake shock. Some of the volcanoes of the Hawaiian Islands are of this type, the lava quietly rising in the crater until it runs over, a molten stream, which flows down the mountain side. The erosion of an elevated tableland representing the second type, may proceed for thousands of years in a comparatively quiet way, gradually carving canyons and gulches in the rock-mass, tending constantly to reduce the elevation to the base level of erosion—the sea level. The third may also be of long duration, progressing so slowly that little or no change is noticeable during a century, but in time producing a marked topographical effect. This movement of the earth's crust is accompanied by occasional re-adjustments of the rock strata, producing what are really only minor tremors of the surface, but which are often fraught with the most serious consequences to mankind, particularly those who chance to dwell in the vicinity of the line of disturbance—the earthquake line.

THE RUINS OF THE CITY HALL, Showing Effect of the Earthquake.

This uplift of a region usually causes strains which pass beyond the limit of elasticity of the rocks, and a rupture results. If the strains continue a fault or displacement takes place, one side of the fracture sinking relatively to the other, and in time—a very long time—the rising side becomes a mountain range. Ordinarily, so slow is this uplift and readjustment of the moving mass that erosion destroys, or, at least, greatly modifies the abrupt scarp which would otherwise result if the movement were quickly accomplished, until no one but the geologist would notice the displacement or understand its significance. The great Sierra Nevada of California is a magnificent illustration of mountain building by faulting, and the subsequent modification of its topography by erosion. The west side of the Sierra is a long, low slope, extending from the east side of the great interior valley of California from 100 to 500 feet above sea-level to the crest of the range, reaching an altitude of 10,000 to 14,000 feet, though probably originally much higher. Its east slope is almost precipitous, descending rapidly to the floor of the Great Basin in Nevada. That line of weakness is also an earthquake line, and some very heavy earthquake shocks have been felt in that locality within recent time, notably in March, 1872, when a terrific shock did much damage in the Owens River valley. That shock was felt for hundreds of miles, but did not extend as far west as the Coast range.

It is the occasional sudden readjustment of the slowly moving rock-mass that causes the shock, and regions along these lines of weakness and displacement are therefore subject to earthquakes. No one can predict their coming or foretell their intensity. It is only safe to say that they are likely to occur at any moment. The more frequent they are the less danger there appears to be of destructive shocks. Almost invariably there is a series of shocks, of which the first is the most violent.

The causes which in past ages have built up mountains and formed valleys, are still at work in exactly the same manner and will continue, as they have, since the dawn of creation, and the recognition of an earthquake line, merely means that geologists have discovered another mountain range in process of formation.

The San Francisco earthquake line approaches the State from the northwest, coming from beneath the Pacific, reaching the mainland near Point Arenas, in Mendocino county, and follows down the coast; it has probably influenced the shape of the shore in that vicinity. It enters Tomales bay, in Marin county, and following that shallow sheet of water to its head, crosses a low divide to the head of Bolinas bay. The depressions occupied by these two bays are undoubtedly due to the fault-fissures. From the mouth of Bolinas bay the line extends out southeasterly into the Pacific again, reaching the coast near Mussel Rock, in San Mateo county, several miles below the Cliff House, and passing inland through Lake San Andreas, Crystal Lake and southeastward through Los Gatos, Loma Prieta, near Santa Cruz, Pajaro, San Juan, lower San Benito valley, Peach Tree valley, Stone Canyon, Chalome valley, Carrisa valley, west of Sunset six or seven miles, through the west fork of San Emedio canyon, crossing into the Mohave desert west of Lancaster, in Los Angeles county, and continuing in a generally southeasterly direction toward the Gulf of California.

Throughout this entire distance of nearly 600 miles this line of movement may be plainly traced by a succession of valleys, lakes and landslips. In several places the fault-throw exceeds 2,000 feet by measurement. It is thought that the fissure has an easterly dip and that the hanging-wall side is sinking relatively to the foot wall or westerly side; it is a normal fault.

The fissure in Marin county may be plainly seen and followed for twenty miles, where it is as well defined as a road, and in some places resembles a railroad cut. Since April 18, the ground has cracked open, bulged up or settled, and springs are flowing where none existed before. There seems to have been a very pronounced horizontal movement, in this locality, to the extent of at least 12 ft. A causeway, solidly built, across the line of faulting was broken and thrown the distance stated, the west side going to the north. Buildings constructed on the line of the earthquake were wrenched apart by this horizontal movement, one being a large barn, owned by a man named Skinner, the other being Shafter's creamery. In that district, as elsewhere, the greatest damage was done to buildings cheaply constructed on insecure foundations. Most of the wooden structures destroyed, with the important exception of the two above mentioned, were built on stilt-like timbers from one to four feet high, without diagonal braces, and the buildings were simply thrown a distance equal to the height of the underpinning. The villages of Tomales, Olema, Bolinas and Inverness were completely destroyed and a tidal wave is said to have swept Tomales bay, which is a fan-shaped sheet of water having its broadest portion opening into the ocean.

Former Earthquakes and Their Discarded Lessons.

From 1865 to 1869 San Francisco and vicinity were repeatedly visited by earthquake shocks, some of them severe. One of the most serious of these disturbances occurred on October 22, 1868. THE MINING AND SCIENTIFIC PRESS of October 24, 1868, contains the following account of an earthquake that visited San Francisco two days previous. Some of the facts stated bear a remarkable similarity to those observed recently.

COLLAPSED BUILDING ON MADE GROUND.

As to facts, they can be condensed into a few paragraphs: Time, 8 A. M., October 22, 1868; direction variously apprehended, but pretty positively either from southeast to northwest or the reverse; buildings generally having been thrown toward the southeast; motion of the surface during the severest shocks more

horizontal than vertical, but in some of the subsequent tremblings almost perfectly vertical; size and height of the earthquake waves, and direction and degree of the force relative to the earth's center unknown, for want of proper instruments to record the same, and comparison of observations in different localities; duration of the principal shock, about 45 seconds; weather dead calm and foggy in town, at Point Lobos a light breeze and hazy, as it has been more or less for weeks; thermometers and barometers about as usual. In the evening the air became beautifully clear and invigorating. The reported focus of severity and damage was, according to many observers, not far from Haywards, in Alameda county; it is safe to say that it was within a radius of 16 miles from that place. As to the degree of damage done to property, it can be understood only by taking a walk through town and observing the houses, walls, cornices and copings that have been thrown down. Probably not over a dozen buildings were utterly destroyed, but hundreds were left with marked evidences of injury. Lives lost, so far as reported at the coroner's office, six; wounded or hurt, about four dozen. Whether the rumbling sound accompanying the earthquake proceeded from the interior of the earth, or from the motion of the loose bodies on the surface, was not apparent, but was settled both ways, by guess."

In the issue of November 7, 1868, appeared the following advice, by George Gordon, on construction of buildings:

First.—That extreme care be taken with foundations, no matter whether on solid or made ground: let the entire bed-frame on which the building rests be a unit, like a ship's keel, and strong enough to bear twice the weight of the building if set up on posts ten or twelve feet apart, and so tied together that you could lift it bodily by a derrick and swing it about.

Second.—Dispense with the use of brick, stone or cast iron, except as an exterior protection against fire. Give these materials nothing else to do.

Third.—Rely on timber and wrought iron entirely to carry the load and resist motion. Mortise all timbers and rivet all iron. Use boiler-plate with angle-iron riveted to it above and below all openings, as sills and caps. No form of iron procurable in this market is so simple, cheap and strong as these combined.

Fourth.—Dispense with lath and plaster, and face the inside walls, and make the ceilings with tongued and grooved lumber. Put up every board and lay every floor so as to form diagonals—bracing in every direction. In nailing, put every nail squarely through the face of the boards and discard the carpenter's foible of blind nailing.

Fifth.—The lower the ceilings and the more numerous the rooms in a building, the stronger the structure. * * * * It is certain that entire safety may be assured to life and property on solid ground by proper attention to the construction of buildings, though we should have earthquakes as severe as are recorded; and it is as certain that all improperly typed walls, or poor mortar and poor bricks, will be tumbled down to the peril of human life, as that earthquakes will occur as they have in the past. Especially should all walls with fronts veneered with stone be immediately taken down. It is mean and cowardly to patch up these structures and plaster up the broken chimneys, trusting that the shock that will hurl them to the dust will not come in your time, or until you have sold the property.

A book published in May, 1869, entitled "Rowland's Earthquake Dangers, Causes and Palliations," contains the following introductory paragraphs:

Truth compels the admission that a portion of California, including the locality around San Francisco, is, at indefinite periods, subjected to the action of earthquakes. It fortunately so happens that the physical geography around this city is of such a character as to largely modify, if not wholly obviate, many of the dangers which are found sometimes to occur when earthquakes take place at or near the seaboard. Allusion is more particularly made to earthquake (tidal) waves and landslips.

The first is found not generally destructive, excepting in the case of harbors immediately open to the ocean, or near the debouchure of bell-mouthed rivers or bays. Landlocked as the harbor of San Francisco is, even if an earthquake ocean wave 60 ft. high was to break on the outlying western shore, it could only penetrate into our harbor by the width of the narrow passage of the Golden Gate, and as it rapidly expands after its entrance to the north, south and east within a short distance from the narrowest part, and would have to travel some miles before its effect could be felt in San Francisco, ere its arrival at that point it would be much modified by the resistance it would have received.

The other danger we are not likely to encounter to any ruinous extent, is that which might probably arise from landslips, notwithstanding the extension of the city front into the bay from time to time, through the interested influence of speculating land-grabbers with former legislatures; as much as possible has been accomplished to bring about so undesirable events as landslips. Owing to the fact that our bay is a comparatively shallow one, we are not likely to witness a newly and solidly constructed wharf, as in the case of the earthquake at Lisbon, destroyed and replaced by deep water in consequence of a landslip. Though partial fissuring amongst the unstable ground of our water lots may take place, and irregular shrinking and elevation of foundations so situated may occur, sufficiently so as to be calculated seriously to damage massive and elevated brick or stone structures which may be erected on such made and generally unconsolidated ground; but a serious landslip need not be apprehended.

In fact, as is well known to its residents, the damage caused by earthquakes at San Francisco and around its bay almost wholly took place on alluvial soil, or made ground, as at Lisbon, the South American cities, and many other places; the next greatest amount of damage having occurred where buildings had been erected on foundations most nearly allied in character to those just noticed.

Scientific Blasting.

(Reprinted from the MINING AND SCIENTIFIC PRESS of August 26, 1905.)

Occasionally miners are required to perform difficult blasting operations, where buildings, flumes or other structures in the vicinity are endangered and must be protected. Experienced workmen can usually overcome these difficulties by the judicious pointing of holes and by the careful use of powder. Not long since, in a city which it is needless to name here, it became necessary to remove a number of concrete piers which had been constructed in the basement of a large brick building. These piers were foundations of large size made from the best material by competent engineers, and had been placed in position as foundations for heavy machinery and had been in use for more than ten years. It became necessary to remove these foundations, and it goes without saying that it had to be done without injury to the building. The foundations were built on a concrete floor and extended upward to about the level of the main floor of the building—the street level. For a day or two, men were engaged in the attempt to remove these concrete piers with picks, hammers and gads, but they made most discouraging headway. One of those interested made inquiry of an expert miner, H. P. Gordon, and asked if the foundations could be mined or blasted out. Mr. Gordon examined the proposition, felt satisfied the job could be done and accepted the contract. After drilling two holes and firing them, there seemed to be no longer an experiment in the proposition and the contract was undertaken. For a period of 35 days, from four to seven miners were employed under his direction in drilling and blasting these concrete piers. In addition to these miners, a crew was employed sledging the larger pieces of concrete and in shoveling the debris into wagons. During this time a total of 470 holes were drilled in the concrete, the most of them being 30 in. deep, a few of them being short block holes; 1,600 ft. of fuse, 170 lb. of No. 2 dynamite and 470 detonators were used. The result of these municipal mining operations was 740 wagon-loads of broken concrete, about 2,220 tons. The work was continued to a successful conclusion, no damage whatever was done, and these unusual operations did not even attract the notice of the passer-by nor of those occupying the neighboring buildings. All work was done during the day, the blasting being accomplished whenever the round of holes was ready. As no permit was obtainable for work of this character, it had to be done secretly; but no unusual precautions were observed. The holes were well tamped with moist clay and each hole was loaded with nearly one and a half sticks of powder, the block holes requiring less.

The success of this operation shows that blasting may be successfully accomplished without damage within the limits of a metropolitan city if the necessary care is exercised in the work.

Drilling along the new iron range west of Duluth has progressed so favorably that both the Pickands-Mather and the United States Steel Corporation interests are putting down shafts. The ore occurs in large bodies, and is of moderate grade, but lies too deep for stripping and hence can not be mined as cheaply as on the Mesabi.

Illusions in the Mining Field.

Written for the MINING AND SCIENTIFIC PRESS by A. LAKES.

Nature is both elusive and illusive. She seems to like to deceive us and crack jokes at our expense, hence the appropriateness of the term lusus naturae, or sport of nature. Every geologist must have met with some of these illusions in his field experience, hence I may be permitted to recall a few that came under my own observation. I remember at an early period in my geological career, digging in some Tertiary formations characterized by fossil leaves and lignite coal, and finding rounded masses which had so close a resemblance to certain fossil corals that I thought I could even name the species to which they belonged. On sending them to a well known paleontologist he pronounced them to be concretions of clay of the kind known in Germany as "teuten." A little later I discovered and sent to an Eastern fossil collector, whose specialty was corals, the stump of a palmetto tree, such as is not uncommon in the Tertiary beds of the table mountains of Colorado, and is there associated with fossil nuts and palm fronds. He wrote to say that we were mistaken as to the fossil being that of a palmetto. It was a coral of Silurian age; and he named the genus and species to which it belonged!

In making the geological survey of a range of mountains in Colorado I came across a belt of limestone, the age of which it was important to know. Fossils, therefore, were eagerly looked for. One day an outcrop of this rock was found, apparently studded with large fossil corals. The specimen was sent East to an eminent paleontologist, and the corals proved to be inorganic concretions in the rock. On another occasion, in Idaho, a belt of rock was found that seemed to settle the disputed age of the formations of that region, by its being profusely spotted with large round spots showing the radiate structure of Paleozoic corals such as those of the cyathophylloid family. The formation was provisionally dubbed Lower Carboniferous limestone. Later experience with the same rock in other parts of the field showed these forms to be those of some radiated silicate mineral of inorganic origin. Moreover, acid proved the rock not to be a limestone but a quartzite.

Noted scientists may sometimes have their illusions. The first discovered horns of the great Cretaceous dinosaur triceratops were supposed by one paleontologist to be the horn cores of the great prehistoric bison. Another equally noted paleontologist was accredited with mistaking the cervical for the caudal vertebrae of a gigantic sea saurian, and in his restoration he placed the head of the animal on the end of its tail. Imagine the wrath of a great sea dragon on awaking from his millenial sleep and finding his head stuck on to the tip of his tail!

If such eminent doctors have their illusions, a wide margin must be allowed for those who have not made geology or mineralogy a special study when they tell of discoveries of petrified rattle snakes, eels, terrapins and cocoanuts, not to mention petrified human corpses and human remains, even in solid granite; also for the prospector in the mining field who says that his prospect hole is in phonolite and contains iridium, tantalum, uranium, tellurium, nickel, cobalt and tin, although to you it may appear to contain only straight hornblende schist.

Igneous rocks are apt to be confounded with those of true sedimentary origin and vice versa. In the early days of the Leadville discovery a whitish gray rock, laminated, crystalline, and apparently stratified and covering large areas, was at first taken for a quartzite of sedimentary origin. An Eastern petrographer, who had never seen the behavior of the rock in the field, from microscopic examination alone, pronounced it also a quartzite, necessarily of sedimentary origin. Later field observations showed this rock to occur as an igneous dike and intrusive sheet, cutting up through the other formations. It now is well known as the "white porphyry;" it is quartz-felsite, and is intimately connected with the ore bodies of Leadville.

Illusions are apt to occur also in stratigraphical and structural geology. In the South Park range there is a remarkable arch visible from a great distance, and locally known as the Horseshoe. This has been pointed out as an example of a symmetrical anticlinal fold. It is simply a body of limestone and quartzite forming the sloping flank of the range which has been eroded into an amphitheater with walls in the form of a horseshoe. The dip and strike of strata viewed from a distance are often as illusive as the familiar example of an irrigating ditch cut along the side of a mountain that appears to carry its water up hill.

In the mining field illusions often occur as to the real size, thickness and position of veins. In one case, responsible parties reported a gold-bearing quartz vein of almost incredible thickness, but examination proved it was a vein whose slab side, exposed by erosion, formed the flank of a mountain. The real thickness was only a foot or two.

In the Carolinas and other Southern States, owing to the country not having suffered from the effects of the great Northern ice-sheet, erosion of rocks and veins is gradual, and it is not uncommon to find the ruins of a vein lying, like those of a fallen wall, close to the present outcrop. So orderly and closely parallel and continuous were these fallen blocks of quartz in one instance that came to my notice, that the thickness of the vein measured across its strike was estimated at 100 feet. A tunnel driven below, where the vein was unbroken and in place, found its true thickness to be only ten feet.

Re-duplication of the outcrop of a vein along a steep hill side by local faulting is often a fertile source of illusion, resulting in long cross-cut tunnels being driven in expectation of intersecting several parallel veins. The dip of a vein outcropping on a side hill is often illusive and in an opposite direction from that subsequently determined by development in depth. The idea that huge quartz veins are necessarily valuable and productive in proportion to their width and length, is an illusion that can only occur to the novice in the mining field.

That the archaeologist, as well as the geologist, has had his illusions from the days of the Pickwickian "Bill Stumps his mark" to the present is exemplified by a man who told me that in digging a well he had come upon a deposit of petrified wood and bones (presumably human) and amongst them a petrified grindstone!

The recent catastrophe in California demonstrates once more the superiority of the miner's product as a medium of exchange. Thousands of dollars of paper money have been lost to the owners; and not only this, but those same thousands have been presented to the banks that issued the money. When a paper bill is destroyed the owner loses and the bank that issued it gains. The destroyed bill can never be presented to the bank for redemption.

State Geologists.—At a meeting held at Chicago on March 31, an organization was effected of the State Geologists of the Mississippi Valley. Messrs. Lane of Ohio; Norwood of Kentucky; Blatchley of Indiana; Buckley of Missouri; Haworth of Kansas; Bain of Illinois, and Assistant State Geologist Bownocker of Ohio, were present. W. S. Blatchley was made chairman and H. F. Bain secretary. It is proposed to arrange for field conferences from time to time and for the frequent interchange of reports and notes of progress among the members of the association. It is expected that through friendly criticism and advice the work of the various surveys may be unified and improved.

A Story in Stone.

Written for the MINING AND SCIENTIFIC PRESS by T. A. RICKARD.

Look at it for a moment. Nearly oval in outline, warm gray in color, it has a surface of irregular texture suggesting that it is composed of minerals of different hardness which have been worn unevenly. It is a piece of granite. Without the aid of a magnifying glass you can see the clear blue-gray of the grains of quartz, the pink-white of the particles of feldspar and the shifting gleam of the bright spangles of mica. It is a waif from the mountains that overlook Denver, in Colorado; a stray bit of stone that was out of place on the tennis court where I picked it up, several years ago. Investigation proved that it came thither amid the sandy loam employed in preparing the smooth surface necessary to the finish of a good tennis court. The material used for this purpose came from certain excavations in a neighboring street where a successful mine-owner was building himself a mansion. Originally, long before Denver existed, even before the buffalo or the Indian roamed over the prairie, this pebble was swept down from the mountains by the flood-waters of the river Platte, which in receding, left the deposits of sand and clay now forming the foundations of the city. As a child wandering over the beach, picks up a shell and putting it to her ear, listens while the wind plays through the delicate portals of pink and white, and hears a voice like the murmur of the sea that tells of strange things far beneath the wave, so we also may listen while this pebble mutters to us garrulously, and tells of its distant home and future destiny. If time can bestow nobility then indeed this bit of stone may command respect. The life of a generation is to the age of this pebble as a dewdrop to the sea. When the morning stars sang together, it held up the foundations of the round world; and when man was yet an unthinking savage, it crowned the crest of the mighty mountains. Its birth belongs to the beginning of days and its childhood was chilled by the cold of the earliest dawn. To trace its origin we must penetrate through the mists of a dim remoteness guided only by that fairy of science which men call the constructive imagination. We judge of that which has taken place long ago by that which we see occurring today. The surface of the earth is the playground of a number of natural forces which have been at work since the beginning. The intensity of their activity has varied, but the method of their manifestation has been the same, because they are the expression of definite laws. Thus it is that the unseen frost which cleaves the mountain summit, the torrent that sweeps the shattered rock into the river which bears them onward, to lay them in the quiet depths of the ocean, indicate to us today how this pebble was formed in the ages past, when that mountain was an island and that river as yet unborn.

Draw back the veil of ages and look at the Earth as it was in the morning of time. A heavy silence broods over the dim vastness of the ocean; upon the frowning coast no bird sings and no flower grows; the winds wander over the leafless lands and stir the waters of desolate seas. There is no life, there is no sound of man or beast, there is naught save a weird expectancy that fills all Nature as in that hour when the darkness is paling before the whispering of dawn. The earth is very still, like an infant asleep. Into a quiet inlet a streamlet is falling. It is singing to the sleeping earth, telling it of the days to come when the great silence shall be broken by the voice of man, and life shall fill alike the darkling wave and the sunlit field. The waters of the streamlet mingle with the sullen surges, and bring to them the tribute of the river to the sea; not gold or silver is it, but grains of sand and bits of rock borne downward from distant hills. At times, when the wind blows and the rain falls heavily, the waters are deeply laden with dark clouds of silt and hasten to the sea as though eager to be unburdened. The sand, the bits of rock and the burden of mud are each delivered to the ocean, to be deposited in ordered sequence upon its outspread floor. This was the seed-time when were laid down the unlike particles which Earth's alchemy should eventually transmute from silt and sand into crystalline granite. The epoch of which I speak is the oldest of which geology takes cognizance, it is vaguely called Archean; so remote is it that no trace of even the elementary forms of organic life have survived, if they existed; so distant that man was not, nor was the footstep of his oncoming heard; so long ago that Time, like the schoolboy who rubs the figures off a slate, has passed his obliterating hand over the faint record written on the rocks and left no sign behind. The record has indeed been rubbed out, but modern inductive science can restore the writing. We observe Nature's handiwork today and thus infer her method in that geologic past. This is the key to all geological research.

To return to our story. The burden of the river was laid down upon the bed of the sea. More material of the same kind covered it. This process of deposition and accumulation went on for a period to measure which the years are useless as units. It took place with the patient slowness that ever seems so admirable to man, whose brief life is but a span, whose existence one unseemly haste. The filling of the ocean by the waste of the land is a matter of every-day observation. The transfer of rock to the sea, by rain, rivulet and river, has been the subject of careful investigation and measurement. By estimating the quantity of sediment carried down to the sea by such rivers as the Mississippi, the Rhine, and the Ganges, it has been determined that the level of the surface of the continental areas is being lowered at the rate of one foot in six thousand years. This estimate takes account of only such material as is transported mechanically by the rivers, and to this must be added an amount, nearly as large, carried in solution. The latter consists mostly of lime, which, being secreted by the multitudinous minute organisms of the deep sea, eventually leads to the building up of the huge thickness of limestone rocks so characteristic of lovely mountain-lands, such as Derbyshire and Savoy.

THE PALACE HOTEL AFTER THE FIRE.

GETTING A DRINK FROM A FIRE HOSE.

Thus an enormous depth of sediment was gradually laid down, covering those earlier silts and sands, wherein lay the elements of the pebble. The deep canyons of Colorado, made by the mountain torrents, afford natural sections of the earth's exterior and make it evident that the granite of the Archean period was overlaid by other rock-masses several miles in thickness. At no one place do we see the complete succession of sediments, because wind and water, rain and snow, have been at work wearing them away during the ages that have passed since they emerged from beneath the wave; nor do we find a simple horizontal bedded series of them in any place, because of the twisting and tilting which they have undergone. This folding is due to the cooling of the earth's exterior and can be explained on the rough analogy of an apple, the skin of which shrinks and crumples as it dries. Thus the granite from which the pebble came, was formerly covered by a thickness of rock exceeding the height of our highest mountains. Such a succession of sediments could not be laid down unless we suppose the ocean-floor to have sunk at a slow rate at least equal in amount to the rate of the deposition of the material. Otherwise the filling of the basin occupied by the sea would put a summary end to the process of accumulation.

Such a supposition is borne out by evidence obtainable today. Proof of a depression of certain parts of the earth's exterior is to be found in the submerged forests which occur, for instance, along the east coast of England. It is but a geologic yesterday (the Pliocene period) that the Rhine flowed across (what is now) the bed of the North Sea and emptied itself within British boundaries. Conditions such as have been described, prevailed in the particular case we are considering. The floor of the Archean sea sunk slowly, while a great thickness of sediment was deposited. The lowermost layers became hardened and consolidated by the weight of those above them. The material destined to make the pebble, lay buried in the darkness of the underworld. Heat and pressure transformed the soft silt into crystalline rock. The transformation was brought about with an infinite slowness and amid an obscurity into which science cannot quite penetrate. We do know that at great depths below the surface of the earth, the temperature is very high. This fact has been indicated by observations made in the sinking of shafts and wells. The average of a large number of careful determinations proves that there is an increase of one degree Fahrenheit for every 48 feet of descent. At a depth of less than ten thousand feet we would therefore find a temperature equal to that at which water boils at sea-level. At the same horizon the pressure from the overlying rock-masses would be equal to about 4500 pounds per square inch. It is certain, moreover, that the rock which, in the after ages, gave us this pebble, was at one time buried under a thickness of sediments far exceeding that just mentioned.

Thus long ages followed each other. The depression of the ocean-bed ceased, and deposition came to an end. A movement of elevation began. Somewhere else, doubtless, a sinking of the earth's exterior helped to counterbalance it. Nature knows not idleness. Upbuilding compensates for destruction, distribution corrects excessive accumulation. Islands commenced to dot the wide expanse of the ancient sea. The material of the pebble, however, was yet far beneath the waves and formed an humble part of those islands that in time became the summits of the mountain range which now keeps guard over Denver. The slow elevation of land continued. As the sea receded, the islands grew both in number and in size until at length they were united into a large mass of land. The evidence of the elevation of parts of the earth's surface is similar in kind to that already given in support of the statement that depression takes place elsewhere. The Pacific side of South America is rising at the present day. On the coast of Norway, at an elevation of 600 feet above the sea, there exist terraces which, from the evidence afforded by the marine shells that they contain, have been proved to be raised beaches belonging to a geological age approaching our own times. Observations have shown that the Scandinavian coast is being elevated at a mean rate of 2½ feet per century. The maximum rate, at the North Cape, is nearly twice as much. Similarly, the land of the Arctic region is also undergoing rapid emergence from the sea.

In this way the land gradually made its appearance above the face of the waters. During this long time of waiting the particles of the pebble had been subjected to the silent forces continually at work in Nature's underground laboratory, so that from sand had come crystalline quartz, from shapeless mud had sprung clear flakes of mica, and out of disordered silt there had been formed an orderly arrangement of elements composing crystals of feldspar. The rock had been prepared with an infinite patience for that later day, when, from lying buried in the footstool of the earth and hidden in the gloom of the ocean depths, it should stand on the top of the wrinkled hills and crown the very summit of the mighty mountains.

Then at length, the rock of our pebble emerged from the sea. As soon as the land arose above the ocean there began that wearing down of the rocks which we term erosion. Tearing down and building up go hand in hand in the inorganic, as life and death in the organic, world. The wind and rain, the frost of night, and the heat of day, were the agents which slowly removed the upper portions of the successive beds of rock which still covered the material of the pebble. After an interval of comparative repose the movement of elevation re-commenced. The island became a continent, the hill became the crest of the mountain range. The sun and snow, the ice and rain, are the patient tools that sculpture the shapeless mass of rock and chisel out the mountain's form. Our pebble became part of a granite peak. There it remained for untold years, a portion of a solitary pyramid of stone, day after day throwing the same clear shadow across the waste of waters, while the centuries went by as the unregarded sand that is tossed by the wandering winds of the desert.

Time, an ocean of time, flowed by. The vast duration of many a geological period passed away. The waters still washed the eastern side of the mountains and the sovereign desolation of the sea covered the prairies of Colorado and Nebraska. Even today if you ascend the Front range and look to the east, the unbroken line of the horizon and the witchery of distance will change the dull dreariness of the plains into the ocean's alpine azure.

At length, in that comparatively recent period known as the Cretaceous, the elevatory movement culminated and the granite peaks gained their maximum height. The sea so long at their feet receded, and its floor became a level plain. At a much later period, however, at a time when the Rhine flowed through the eastern part of England, the depression of a certain portion of this area resulted in the formation of a great freshwater lake which overspread the present site of Denver. Think of it as it was then, a wide waste of waters that in storm dashed vainly against the battlemented cliffs that now overlook the towns of Boulder and Golden, and in calm, reflected the severe grandeur of those peaks which were the silent sentinels that guarded the treasures of Colorado when the Spaniard came, and are now the minarets of snow that end the picturesque perspective of Denver's streets.

The material of the pebble still rested on the mountain top. It typified those things which out of weakness are made strong. What was once soft sediment had become crystalline rock; once abased in the deep, it was now exalted above all the earth and "out of the substance of it the axe of God had hewn an Alpine tower." Long ages it stood on high, fronting the dawn and glowing in the sunset; beneath it the mighty hills bowed in serried lines, and far below the prairies faded away in tremulous blue.

But its destiny was yet unfulfilled. There came a day when a mightier power than the storm, a more resistless force than the wind tore away a fragment of that mountain peak and the original of this pebble rattled down the dark ravine and fell upon the snowy surface of a majestic glacier. A drop of the rain of heaven had found a resting place in a cranny of the rock, the cold of night and the heat of day had alternately contracted and expanded this particle of water, so as to make it a resistless lever which had wrenched the stubborn rock and sent the fragments headlong down the cliff. There is a lesson here. The natural forces which command our attention, are not the mightiest. The unseen hand of the frost is tenfold stronger than the raging torrent. Many a volcano in its sudden and catastrophic outpouring of molten rock fails by such fitful activity to eject as much material as the thermal spring whose stream, bubbling daily for centuries, delivers an unvarying quantity of salts dissolved in its beneficent waters. The daily tribute seems insignificant, but the total is more than the outpouring of a Vesuvius.

The glacier received the stone and carried it forward in majestic advance through the long files of onlooking mountains, until, at the opening of a sunlit valley it was delivered to the stream, the waters of which were fed by the melting ice. Borne along, now more rapidly, partly pushed and partly carried, it became worn by attrition so as to lose its sharp edges and to assume its present shape. The chip of rock broken from the mountain crest became the pebble of the stream. Rest it had none, continually traveling onward and downward, sometimes lingering at the bottom of a quiet pool while the trout darted past, sometimes making sweet music as it played among the harpstrings of dark water that fell down the sunless ravine, but journeying ever onward to fulfil its destiny.

The mountain torrent delivered it to the river; the Platte received it, and bore it to the plain.

Then came a day when the heavens were darkened by hurrying stormclouds, when lightning flashed from peak to peak, when floods of warm rain fell upon the snowfields and every rivulet became a river, every river a boiling torrent, when a great rush of water swept down from the mountains and spreading over the plains, covered them with the sand and gravel in which our pebble was found.

But the end is not yet. That pebble, like all created things, has a course to run and a destiny to fulfill. It must return to the condition from which it came, and so complete the cycle of change. We cannot stay its wandering, we may put it on a shelf or throw it into a corner, but it will fulfil its purpose nevertheless. The day will come when we shall be deemed "ancients of the earth," and this geologic age in which we live will recede into the distance to become the "morning of the times" to those that follow. Then this pebble, shivered by the frost of night and shattered by the heat of day, will again be resolved into fragments, to be gathered by the rain and given to the river; and the river will bear them to the ocean where they shall again "sow the dust of continents to be."

This ends the story. There is poetry even among the pages of geology. The history of this globe of ours is a grand epic the cantos of which cover geologic periods of vast duration. The ancients felt this, for they loved to speak of the earth as a sentient being whose changes were typified in their own lives. Much of that simple feeling has come back to us in spite of the artificiality of modern days, and has been voiced by the great poet of our time.

"There rolls the deep where grew the tree,
O Earth, what changes hast thou seen!
There where the long street roars hath been
The stillness of the central sea."

The production of spelter in 1905, as given by Charles Kirchhoff, of the United States Geological Survey, was as follows:

States.	1900.	1901.	1902.	1903.	1904.	1905.
Illinois and Indiana	38,750	44,896	47,096	47,659	47,740	46,606
Kansas	62,136	74,240	86,564	88,388	107,048	112,974
Missouri	14,741	13,083	11,087	9,994	12,150	11,844
Colorado				877	4,871	6,599
East and South. States	8,259	8,603	12,180	12,301	14,893	24,513
Total	123,886	140,822	156,927	159,219	186,702	202,586

Platitudes are a stumbling block to the shallow novelty hunter, and axioms are a weariness to the multitude; but to the earnest they are the renewal of wisdom every morning; they rekindle and illuminate the common sense of humanity which at times burns very low. Those which we have considered are among the most helpful. Three things are vain in our university life: faith without works, morality without religion, and precept without example. All our investigating and teaching and professing; all our sapience and assurance and mannerisms, will go for naught without a labor which is worship, a sympathy which is self-denial, and permanent standards which we adopt only for the better realization of the ideals which they express.—William M. Sloane at Columbia University.

Concrete. The proportions of materials used in making concrete vary according to the use to which it is to be put. It ranges from one part cement, to two to four parts clean sand, and four to ten parts clean crushed stone. If mixing must be done by hand, (a good automatic mixer is preferred) it should be done in the following manner: The sand and cement must be thoroughly mixed dry, then sufficient water added to make a plastic or wet mortar, and the whole thoroughly mixed again. The stone having been previously wet down, should then be added, and the whole mass mixed until every stone is completely covered with mortar. The concrete thus mixed should be immediately placed in position and rammed until excess mortar shows over the entire surface. Where surfaces are to be exposed, either a facing of one cement to two of sand must be used and placed in position as the mass of concrete advances, or else the cement should be forced back by pushing down flat-bladed shovels along the face of the form, thus allowing the richer mortar to run in next the form which makes a smooth impervious surface. No concrete which has attained a partial set in the mixing bed should be used.

Perspective in Mining.

(An Address to the Engineering Society of Columbia University.)

Contributed to the MINING AND SCIENTIFIC PRESS by J. PARKE CHANNING

The melancholy Jacques in 'As You Like It' says, "Call me not fool till Heaven hath sent me fortune." Call me not fool till Fortune hath sent me the opening up and equipment of a mine; for in mining there is so much that is not teachable, nevertheless learnable, that unless a man has this instinct, inherent in all capable persons, he can never hope to achieve success as an engineer. Each mine is, so to speak, a law unto itself, and not until the engineer recognizes this can he get true perspective in mining.

When you leave school and start out in practical life there are certain things that you have heard in your studies which have impressed themselves upon you. The reason for that impression would be hard for you to say. It may be that some particular thing had interested you because of some previous experience of yours. As a result you are really not able to define the proper relations between things, and that is one of the reasons why a man, after he graduates, should not start immediately on consulting work, or to take entire charge of any enterprise.

It should be remembered that your course in the school is simply one of preparation; in other words, if you want to learn the mining business you have got to go into the mines and study it, just as if you were going to learn the dry-goods business you would have to go to a dry-goods store; to learn banking you would begin as a messenger or clerk and work your way up. The only advantage of going to a school of mines is that you get a technical education; you have a certain ground-work, which helps you out, and you also have gained a very important thing in knowing how to study, and knowing how to put two and two together so as to make four, and not three or five.

When a man goes out I would advise him to get a position at some mine or metallurgical works; it is not always desirable that it should be a particularly large mine or works; often he gets a better knowledge of what is going on by working in a smaller mine. When you take your first position in a mine I would advise you to work underground. This gives you an opportunity of watching mining work—sinking, drifting, stoping, timbering, tramming,—and it particularly gives you your first idea of the proper relation of things.

About fifteen years ago I was running the East New York mine at Ishpeming, Mich., and Mr. T. F. Cole, who is now manager of all the iron mines of the United States Steel Corporation, was running the Queen group of mines at Negaunee, Mich. We used to compare cost sheets, and his cost of development amounted to 2.5 cents per ton and mine amounted to 25 cents per ton. The reason for this was that his ore-body was in area ten times as large as mine, and, although my shafts and crosscuts were of the same length as his, the decreased tonnage was against me. This simply shows how the cost of development has got to be watched in its reference to the size of the ore deposit.

Take for example the opening of an iron mine at Lake Superior; after first striking the ore, the proper thing to do is to sink a small one-compartment shaft, one big enough for a good size bucket and ladder. With a shaft of this size you can get down to the ore and you can yet out a good deal of ore. After you have gone down a hundred feet and have your drift, and have some idea of the size and shape of the orebody, you can, if you find the conditions warrant it, put in a larger shaft.

I have seen prospecting or development schemes wrecked by the man in charge spending a lot of money and time in sinking what he called a "working shaft," and when he got down found that there was nothing to work, or at least it could have been worked through a small shaft. In prospecting or small mine work you don't want to put in any brick set or water-tube boilers, and you don't want too large an engine. You want to get a cheap portable locomotive or upright boiler. It won't hurt to burn a few extra cords of wood.

On the other hand, you also want to try to get the idea of how far you should go on equipment without going to the point of over-equipment. Suppose, for example, that you finally take hold of a mine that is developed and is producing ore for shipment, and you find the mine is fairly well equipped when you get there. You may find a great many things that do not satisfy you or do not come up to your ideas. You may find a shaft-house that was badly arranged; you may find that the hoisting engine is one that uses too much steam, and the compressor is not the right thing; that the shaft is crooked, and there is no skip only a bucket. Now, don't be in too much of a hurry to tear all of these out; go ahead and see what you can do with them, until you get to the point that you can definitely see and figure it out in dollars and cents, just how much you will save if you were to sink a new shaft or straighten out the old one; or if you were to build a new engine house or put in a new engine.

Some of the men who were at Copperhill, Tenn., last summer remember the excellent plant we had at the Burra Burra mine; there was a brick house containing water-tube boilers; there was a big power-house which contained a first-motion hoisting engine, together with a cross-compound, two-stage, air compressor, with room to put in another one. There was also a shaft crusher house with its paraphernalia. When I equipped that mine I had at the same time the idea of later putting in a similar equipment at the London mine, and I had the plans drawn and everything arranged for it. But, after carefully thinking the matter over and seeing the tonnage that came from the latter mine, I finally came to the conclusion that I would make a great mistake to take this mine, which was only 500 ft. long and 30 ft. wide, as compared with the Burra Burra, which was 1,600 ft. long and 80 ft. wide, and give it the same equipment, notwithstanding the fact that it would be very nice to have two or three mines all provided with exactly the same type of equipment. So, instead of putting in a duplicate of the plant we had at the Burra Burra, I simply bought a cheap geared hoist and put it back of the London shaft in a small building covered with corrugated iron, and we used the same boilers that had been used there since the beginning of the development work.

The more you work the more you will find out that there is absolutely nothing that cuts down cost as much as tonnage. Another suggestion is this: When you start up a new mine don't be in too much of a hurry to build a nice house for the manager or superintendent, or too grand an office building. That is one of the things that an English engineer at a new mine looks after before anything else. The first thing he does is to build himself a house, and then he goes ahead and develops the mine. If your mine happens to turn out all right it is very good to have lived well while developing it; but if it does not turn out all right, then the house that you built will be a monument to your folly. While I don't advise you to open up a mine and live in a hut or tent all winter, you must use proper judgment as to the kind of a house you do build.

Take, for example, the cost of underground haulage; you know that the tendency nowadays is to do underground haulage, wherever possible, with electric locomotives. It figures out as very economical, and the electrical people will be only too glad to estimate on the cost of installation and operation, but you must remember that it is the opinion of most mining men that for medium distances, say 500 or 600 ft., you can do nothing better than to use man power, for the reason that you have to give the man loading the cars a rest and he gets this rest, if the grades are properly made, by pushing his car out and waiting a minute or two at the shaft until it is dumped, and then pushing the car back again. This is a change from loading the ore, and so he trams really for nothing.

At one of the mines in Bingham Canyon, Utah, they mine about 1,000 tons per day, and it comes out from one adit, where it is handled by four horses—two on each shift. At one of the adjoining mines they put in an electric tramming plant, and yet the tonnage they have could readily be handled by two horses. It does not take much figuring to see that two horses are cheaper in first cost and up-keep than an electric installation. So, therefore, in adopting any particular apparatus, or any particular method, you must take into consideration the tonnage and conditions under which it is operated.

When you come to metallurgical work this factor will be strongly emphasized. Remember that you do not want to get things too automatic. I remember when I was talking with the late Richard P. Rothwell, of "The Engineering & Mining Journal," about Mr. Edison's iron-ore plant out in New Jersey; he said that the plant was too automatic, and that once in a while there should have been an Italian with a shovel. You will notice that at some concentrating mills they may have a certain product that has to be handled or moved to some other part of the plant for re-treatment. In a small mill that amount is so slight that one man could shovel it as it accumulates, so that under these circumstances it is no use putting in an elevator or some other apparatus to handle this small amount of material. In a large mill, however, it may be really necessary to have something to carry your concentrate and middling from various points where they are produced to a central point.

In metallurgical work, modern practice is along the line of labor-saving devices, but in a small blast-furnace plant, where you have but one furnace, it is a question whether it would pay you to put in a so-called automatic charging apparatus. This is the method in use at large plants, where the ore is run into cars and pulled by an electric locomotive to the furnaces. I believe that there is no doubt that one could get better metallurgical results in copper-blast furnaces by hand-charging than by dumping the charge from cars, but the cost would over-balance the metallurgical saving.

In places like Mexico, where wages are only 75 cents to one dollar per day, it is sometimes impossible to get enough men to do the work, which, of course, necessitates your putting in labor-saving devices, not to save money, but to run at all. When we started in Tennessee labor was a dollar per day, and we seriously considered whether it would be advisable to put in a charging apparatus for the furnaces. But I felt that in the South it would be difficult at times to get labor, and so, fortunately, I put in electric charging cars, and they have been a great success. This question of shortage of labor is important in an agricultural country. Take for example in Mexico: In the springtime the men go off to plant their corn, and when it comes autumn they go off to harvest it. You notice the same thing in Tennessee. In the spring the men go to plant their crops, and when the time comes to harvest, off they go; they do this regardless of whether it would pay them better to attend to their farms or not. For instance, in Central Mexico, where laborers receive two or three dollars a day, a man will leave his position and go to harvest a $30 crop and lose $60 in wages.

A man can frequently be penny wise and pound foolish in refusing to advance the wages of good men. So do not always be looking at your payroll with the idea that the best way to economize is to cut down wages. The first thing that an untrained man does when he goes to a mine is to try to find some way to save money. He looks at the payroll and finds that it amounts to $10,000 per month and that the supplies are $5,000, and that the mine is running behind. He concludes that the only way to remedy the matter is to cut wages. He does this; his men loaf, or the best leave him, and he runs still worse behind.

You want to be careful to see what work per man per day you get, so therefore it is essential to remember when you are engaging labor to pay about the same wages that are being paid by others in the district, and be slow about reducing wages, but see that the men work. Try rather to keep your wages a little bit higher than anybody else, so that you can get the best men; let the other fellows keep the poor men. If you get a good man and pay him 25 cents more per day, he will probably do a great deal more work.

Perhaps the young men who were down in Tennessee remember the two big trammers we had at the Burra Burra mine. One of the men has been with us at least four years. He is a stout, husky fellow, and would load just as many cars as two ordinary men would do. The ordinary man would load ore at 18 cents per car and perhaps get out 20 cars per day, while this one man would get out 16 or 18 cars himself. Now, then, think of the money we would save if all our men were of that kind. It would mean that, if we wished to, we could practically double the output of our mines.

Another thing you want to bear in mind is this: Never be afraid to engage a man who knows more than you do; that is just the kind of a man you are looking for and just the one you want. A young man, as a rule, never wants to engage a man, or have any man under him, who knows more than he does. If you engage a foreman, get one that knows all about the handling of men. If you get an engineer, get an engineer that knows something that you do not know, one who has had lots of experience at other mines; his experience will be of great benefit to you in solving new problems that will arise.

While I have referred more to the economical details of operating, there is another perspective view which takes a long time to get, and that is a comparative idea as to value of mines—whether there is really a mine or not—or whether it is going to be a small mine or a large mine; and the only way you get that is by looking at as many different mines as you possibly can. Never lose a chance when you are traveling or looking for a job to go into a mine and through its workings. If you visit a mine of any importance, try to get a position in the underground workings, because that is one of the things they cannot teach a man and which can only be acquired by long experience and by looking at different properties.

I might say that your college experience has enabled you to make a quick decision. Really the main thing in mining is the capacity to see a property in a par-

tially developed stage and from that inspection be able to determine whether it is going to be a mine. You find that it has 50,000 or 60,000 tons of ore in sight, and that it seems to have the earmarks of a large deposit, and you will advise your people to take it. If you have the courage of your convictions, if you think that it is good, stick to it and do not let the property go by. It is a great deal better for a man to make a mistake once in a while in getting hold of a property that does not turn out well than it is to let a good one go by. Still, however, if a young man makes two or three of these mistakes, it is likely to go against him in the long run; so I say to you, that when you start out, keep away from making these examinations, or, at least, from consulting work. It is very nice for you to go in as assistant to some engineer and help him in sampling and making determinations as to the value of mines, but do not get yourself into a position where you are called upon to pass judgment upon mines, because you may get yourself into some bad predicament, which will take a long time to live down.

I do not want you to understand that I would recommend a man starting out to begin as an assistant for an examining engineer. It is pleasant work, but I think that if one starts out in it he is liable to get rather a bad habit. Remember that the really successful consulting engineer is that man who has the capacity to size up a mine and to determine its value, and who thoroughly understands the cost of operating it. The whole tendency to-day is toward the mining of low-grade orebodies, and the question of operating expense is one of vastly more importance than the question of sampling and assaying the ore. For example, take the large porphyry orebody in Bingham Canyon, Utah; a man who examined it stated that it averaged less than 2%, yet his samples checked those of the mine manager within 0.01 per cent.

I recently examined a concentrating property in Nevada and the ore ran slightly under 3%, my samples checked on one of the mines within 0.03% and on the other mine within 0.02% of the results of the management. So you see that sampling, to a certain extent, is mechanical. In a large concentrating proposition of this kind the main thing is, what is it going to cost to mine and treat the ore. The original report on this mine by the manager had been taken over to Paris by the senior member of a large banking house and the figures as to the grade of the ore and the cost of treatment submitted to several French engineers, who simply laughed at the thing, and said it was impossible to treat ore of that grade. My examination showed that the conditions were exactly right for a big property—one that could be handled and show a large profit. The trouble with the French engineers was that they had not kept up with the latest practice in concentrating or the latest methods in reverberatory smelting, and, while they were only two or three years behind, they might just as well have been twenty years behind the times. Therefore, I say to you that one of the most important things for a successful consulting engineer to have is a good knowledge of operating; the only way to get a true idea of operating is to work your way up from the bottom.

There is also one other important thing in mine examination and mine operation, and that you have to study and pay particular attention to, and that is the geology. If it is copper, you must keep yourself posted thoroughly on secondary enrichment; if you do not, you will have difficulty in getting along. It was about eight years ago that I examined the Highland Boy mine in Utah; the fourth and fifth levels were then opened up and showed an average of about 7.3% copper and considerable gold and silver, but I could see plainly that a good deal of that copper was in the form of chalcocite, which I knew was secondary. Another engineer, who came out about the same time, looked the property over, and, although he agreed with my sampling and assaying, he predicted that the sixth level would only go one per cent; he gave too great a weight to secondary enrichment; later developments showed that the lower levels went four per cent, and the result was that his people lost a fine property. This simply shows the necessity for keeping thoroughly up on the literature of ore deposits, because it is being added to day after day with great rapidity. Of course, this is not as absolutely essential to you as a knowledge of operating, because there are certain geologists who make a specialty of studying ore deposits. In case of necessity, you can get a man of this kind to help you out, and you perhaps may be able to make certain economic conclusions which he was not able to see. Some of the big mining companies keep an economic geologist at work all the time. In a small mining company that is impossible, and the geologic work devolves upon the mining engineer.

When you get a mining engineer you want to get a man that has been well schooled, one who understands geological conditions and is able to lay out future work. This has been done in the Butte mines in the last three or four years, and I believe there is not a single crosscut in the mines of the Amalgamated that is not laid out on paper in the office before a stroke of work is done underground. Of course, you get a much better training now in geology than I ever got, not because your professors are any better, but simply because the subject is more thoroughly understood than it was twenty years ago.

Therefore, I say to you to study economic geology just as much as possible, because the question of ore deposition is one of such vital importance that you must forever have it before you. Whenever you see an orebody, and it is a particularly rich one, you want to look at it carefully and study the conditions and try to determine whether these conditions exist a hundred or a thousand feet down, or whether they are only local conditions. This capacity to see is one of the things that you can only learn by going around and seeing, and remembering what you see.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The light-colored flint-like rock from Nashville, El Dorado Co., Cal., is felsite.

The porphyritic rock from Virginia City, Nev., is andesite-porphyry. It shows no indication of mineralization, in a mining sense.

The rocks from the Black Bear Mine, Trinity Co., Cal., are No. 1 greenstone, probably diorite much altered; No. 2, a metamorphic clay rock.

The green-stained rock from Lusk, Wyoming, is quartzite, a metamorphic sandstone. The green mineral is copper carbonate (malachite).

The rock from Soulsbyville, Cal., is pegmatite, a coarse-grained dike granite. The large white crystal in the specimen is albite, (lime-soda feldspar).

The rocks from Pichacho, Cal., are: No. 1 amphibolite-schist; No. 2 felsite containing much finely disseminated pyrite; No. 3, diorite; No. 4, rhyolite tuff; No. 5, hornblende-andesite; No. 6, augite-andesite.

Unless the manganese ore discovered by the Montana prospector in his tunnel near Marysville contains silver and gold, in payable amount, it is very doubtful if the ore is of present value. Solid manganese ore (the only valuable kind in any place), needs no concentration. Very often a manganese outcrop covers a gold and silver vein.

The rock from Paterson district, Nevada, is meta-diabase. A thin section of this rock shows typical uralite resulting from the alteration of augite crystals, the nucleal portions of which, in several instances, are perfectly preserved, exhibiting clearly the characteristic cleavage approximating 87°. The uralite also shows in part the hornblende cleavage, though considerable portions are fibrous. The black borders of magnetite about these altered augites and also surrounding the biotite, are typical. It is a most interesting rock. Veins may occur in rock of this description, but it is improbable that the particular piece sent for identification came from the immediate vicinity of a vein, or ore deposit.

The rocks from Goldfield, Nev., marked R. H. M. are as follows: No. 10, a crystalline-granular mass of hornblende and soda-lime feldspar, with little quartz (Diorite); No. 11, Rhyolite tuff; No. 12, Diorite-aphanite; No. 13, Diabase; No. 14, a very silicious altered rock, probably originally Diorite; No. 15, Felsite; No. 16, Diorite; No. 17, crystallized quartz in a metamorphic clay rock, which would ordinarily be called slate. The quartz has crystallized from solution in a mass of brecciated slaty rock, and it seems probable that the larger fragments of the rock mass have been surrounded by granulated or pulverized material which was more readily dissolved, carried away and replaced by the quartz, atom by atom, than the large pieces of rock. It is inconceivable that the angular fragment of slate was suspended in space in an open crevice while the silica slowly deposited around it.

Personals.

J. H. Curle is in Japan.

Arthur Winslow has returned to Boston.

H. W. MacFarran is at Bingham Canyon, Utah.

Walter G. Perkins is now stationed at Ely, Nev.

John Hays Hammond has returned to New York.

R. H. Toll is examining mines in Boulder county, Colorado.

H. P. Garthwaite has returned from San Francisco to Salvador.

E. H. Jeffries has moved from Denver, Colo., to Yreka, Cal.

Leonard D. Sivyer is examining mines near Tonopah, Nevada.

Albert P. Low is now director of the Canadian Geological Survey.

R. G. Brown has his office now at 2031 Sutter St., San Francisco.

W. S. Noyes has an office now in Room 25, Albany Block, Oakland.

George S. Binckley, on his return from Mexico, is now at Berkeley.

D. M. Riordan of New York is at the Bully Hill mine, in Shasta county.

Arthur H. Halloran has returned to Berkeley from the Nevada gold fields.

Frederick Grundy has left Los Angeles to examine mines near Florence, Arizona.

S A. Worcester, of Victor, Colorado, is engaged in professional work at Telluride.

W. Spencer Hutchinson, of New York, is examining mines at Grants Pass, Oregon.

H. L. Charles was in San Francisco during the fire; he has returned to Butte, Mont.

Leonard Beckwith has been appointed mine inspector for the Mysore district in India.

J. D. Spargo is now superintendent of the Enterprise Mining Co., at Kingman, Arizona.

F. Lynwood Garrison, on his return from Santo Domingo, is on a visit to Joplin, Missouri.

H. W. Turner has returned to Portland, Oregon, from Kiam, Alaska. He is now at Berkeley.

Edward Westall, Supt. of the Marguerite mine, Sierra County, Cal., was in San Francisco lately.

L. P. Shackleford, of Juneau, Alaska, was on a visit to San Francisco during the catastrophe.

F. Wallace White will be at Haileyburg, Ontario, Can., for the coming three or four months.

Bruno Newman has been appointed engineer of the Santa Francisca mine at Asientos, Mexico.

H. H. Miller, has been appointed manager of the Mineral Development Co., at Guanajuato, Mexico.

U. S. Grant, of Northwestern University, will explore for iron ore in northern Minnesota this summer.

D. C. Jackling and R. C. Gemmell of Salt Lake City, have been visiting the iron mines in Minnesota.

A. C. Crider, late of the United States Geological Survey, has been elected State Geologist of Mississippi.

George E. Collins of Denver has been appointed general manager of the Newhouse tunnel at Idaho Springs.

Horace V. Winchell retains a connection with the Amalgamated Copper Co., becoming consulting geologist.

L. K. Armstrong is making an examination of the Q. S. Mine near Loomis, Wash., in company with A. M. Dewey.

E. W. Biedler, superintendent of the Palmer Mountain Tunnel and Power Co. was in California on his way to New York.

Frank H. Taylor of the Westinghouse Company has resigned as vice-president in order to take a prolonged rest in Europe.

J. J. Rutledge, consulting engineer of Baltimore, is making an examination of certain of the Illinois coal-fields for the State Geological Survey.

Samuel Calvin has been made State Geologist of Iowa again succeeding F. A. Wilder, resigned to undertake exploration for gypsum in Virginia.

Horace V. Winchell, chief geologist for the Amalgamated Copper Co. at Butte, has resigned. Mr. Winchell has received an appointment with the Great Northern Railway Co. and will reside at St. Paul.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Sand used in concrete should be sharp, clean, and free from clay, lime, loam or organic matter, and should be thoroughly cleaned.

Porphyry accompanying a vein in any kind of rock is an indication of depth rather than size of ore deposit or richness of the ore.

It seldom pays in mines to drill holes deeper than 6 to 7 ft. even with machines, except possibly in large stopes, where deeper holes may occasionally be employed to advantage.

In some States legislation has been passed requiring district mining recorders to turn their records over to the county recorder. Such legislation is valid, and must be complied with.

Felsite is an intrusive dike rock, and not a volcanic or effusive rock. In the latter class the nearest approach to felsite is rhyolite, from which it is often difficult to distinguish it without the aid of the microscope.

Some of the gold mines of Georgia afford examples of the occurrence of coarse gold in slaty and schistose rocks without the appearance of any vein structure. The gold in one of these mines, the Boly-Fields, occurs with bornite, pyrite and dolomite.

There are doubtless numerous cement-making plants in Mexico, as cement has been employed in the building of the more important structures, such as bridges, aqueducts, etc., for nearly 400 years. 'Concentrates' is not informed as to the whereabouts of these works.

Bad running ground in mine drifts may sometimes be passed in safety, and securely held permanently, by the use of concrete. The forms must be quickly placed and the concrete made of liberal thickness in order to resist the crushing from the rock.

Portland cement is a product of a mixture of clay and calcium carbonate in definite proportions, calcined at a high temperature, and reduced to a fine powder. Natural cement is a similar product made in the same way from a natural argillaceous limestone. It also often contains carbonate of magnesia.

A fall of three inches per mile in a smooth, straight channel will give a velocity of about three miles per hour. The river Ganges, in India, has a fall of 800 ft. in a distance of 180 miles from its mouth. In flowing this distance a floating object requires more than a month to descend this 800 feet.

Auriferous sulphide ores occur in almost every kind of rock that is recognized as a distinct species. Granite, diorite, diabase, andesite, slate, schist and limestone are all wall rocks of gold-bearing veins. Volcanic glass and extremely basic rocks, like basalt, are not known to be gold bearing.

The owner of a mine must give to the owner of an adjoining claim extra-lateral support, that is to say, he must carry on mining operations in such a manner as will prevent the caving of the adjacent ground into the excavation he makes, and in the event of ore caving into his workings from the adjoining claim he cannot appropriate this ore to his own use. He is also liable for damage done.

The atomic theory regards matter as composed of infinitely small particles, called atoms, which are united to form molecules. The matter which comes within the conception of our senses is produced by the aggregation of an innumerable number of these molecules. These atoms and molecules are supposed to be in a state of perpetual motion, though always occupying a definite position with relation to each other.

Silver cyanide is soluble in an excess of potassium cyanide, with the formation of a double cyanide of silver and potassium, but at a certain point in the mixture of silver nitrate and potassium cyanide, the silver cyanide becomes insoluble and falls as a grayish flocculent precipitate. The quantity of silver nitrate necessary to be added before this precipitation occurs is recorded on a burette, and from the reading is determined the strength of a given cyanide solution.

The cost of concrete work varies greatly, depending upon the character of the work and proportions of cement employed. In break-waters, and in certain river and harbor improvements, it ranges from $4 to $10 per cubic yard; in sidewalks, curbs and gutters from $10 to $18 per cubic yard. In first-class foundations for machinery, the cost per cubic yard is about the same as for sidewalks.

The failure of a party to comply with a mining rule or regulation can not work a forfeiture, unless the rule itself so provides. There may be rules and regulations which do not provide that a failure to comply with such provisions shall work a forfeiture. If so, a failure will not work a forfeiture. (Bell vs. Bed Rock H. & M. Co., 36 Cal. 214.) This is the rule adopted by the courts of California and Arizona, but the contrary rule is applied in Nevada and Montana.

Where conditions are suitable, a good reservoir can be built by simply covering the inner surface of an excavation in sand and gravel with cement mortar. In one instance a reservoir was so formed, by coating to the depth of 1½ in. with cement mortar the sloping sides of an excavation in sand and gravel when the surface was damp. The mortar employed consisted of one part cement to five parts sand. This basin has held water without leaking for years under a head of 16 feet.

The mining laws of California do not require that mining claims be recorded, and provide no penalty for failure to record. Consequently the claim located in September, 1905, which was properly staked, in accordance with the legal requirements, is still a valid location, and the attempt of another to re-locate in November, 1905, is unavailing, as he has no shadow of title to the claim. Some States require recording of locations, and failure to place the location on record invalidates the location.

Agitation of finely pulverized auriferous sulphides in cyanide solutions, has resulted in satisfactory extraction at many places, and where power is inexpensive this method is probably to be preferred to any other. As high as 96% extraction was obtained by Dr. Scheidel on slime from the canvas plant of the Utica mine at Angels, Cal., but the extraction fell to below 70% on the ordinary concentrate from the vanners. This seems to indicate that fine grinding is what is required for high extraction from sulphides.

The final blowing out of a large copper furnace presents no peculiar features. The blast should be reduced as the charge sinks, and as soon as the slag stops running, the breast-wall, and if extensive repairs are imminent, some of the rear and end panels should be knocked in, and all stock and fuel dragged out, until a tolerably even bottom is reached, which needs no preparation for the succeeding campaign. A blast furnace may sometimes be blown out satisfactorily by charging only coke and limestone. It is said to leave the furnace clean and do no damage to the walls.

In a few mills, feeding by hand is still practiced, but it is doubtful if the most painstaking hand-feeding is as satisfactory as the work of the best automatic feeders. Those who favor hand-feeding contend that the five stamps in a battery are not equally efficient, and that hand-feeding will equalize this difference in crushing capacity; while this is true, to some extent, hand-feeding is not always intelligently performed. A man who has brains enough to discriminate between the performance of the individual stamps of a battery is usually worth more in some other position than that of ore-feeder.

In the early history of the Combination mine at Goldfield, Nevada, the high-grade ore, running between $150 and $250 per ton, was shipped. As the value of the ore increased the transportation and reduction charges also increased. The company milled ore running very much below $150 per ton. In one portion of the mine a small shoot of ore was found which contained over $1000 per ton. To avoid paying excessive transportation and smelting charges it was decided to mill this high-grade ore. Over $750 per ton was obtained in the batteries and on the outside plates, and the tailing was carefully impounded, dried and shipped. This tailing (not concentrate) containing less than $300 per ton, came below the special high rate, and as the smelters paid 95% of the value, the company realized an unusually high percentage of the precious metal content of their ore, at a minimum cost.

Production of spelter in Kansas was very close to full capacity. Illinois will show a decided increase in output in 1906 and 1907. Reports from producers of spelter show that stocks declined from 6,089 net tons on January 1, 1905, to 4,486 tons on January 1, 1906, a decrease of 1,360 tons. Since the imports of spelter in 1905 were 521 tons, as compared with 341 tons in 1904, and since the exports of domestic spelter and the re-exports of foreign spelter were 5,535 tons in 1905, as compared with 10,149 tons in 1904, the estimated home consumption figures out 199,125 tons in 1905, as compared with 180,911 tons in 1904 and 154,381 tons in 1903. As in iron and steel and in other metals, the consumption of spelter in 1905 broke all records and was very close to 200,000 net tons.

It is not an uncommon thing to find bright gold in the tailing from gold mills, that will not amalgamate. This gold may not be particularly fine, but is covered with a film of some substance which prevents contact of the quicksilver with the gold. The film may be very thin, so much so as to be transparent, but it is sufficient to prevent amalgamation. This film may usually be removed by attrition, such as would result from grinding in a pan or arastra. It is a well-known fact that the simple Mexican arastra is one of the best amalgamating devices in use, and it is no doubt due to the fact that the arastra brightens the gold particles and thus prepares them for amalgamation, in a far better manner than is possible with stamps or other pulverizing devices which lack the abrasive action of the arastra or the grinding pan.

Purple of Cassius was discovered in 1683 by Cassius of Leyden. It contains gold and tin oxide, and is employed in coloring glass with various shades of violet, crimson and purple. There are several methods of preparing this substance, one of the best known being the following: Half a gram of gold is dissolved in aqua regia, composed of 16.8 grams hydrochloric acid, and 10.2 grams nitric acid, and the solution is then diluted in 14 liters of water. To this solution is added, drop by drop, a solution of a mixture of proto-chloride and ter-chloride of tin is dropped, little at a time, into 18 finely divided tin is dropped, little at a time, into 18 grams aqua regia, made as directed above but with the addition of 5 c.c. water. The reaction is checked by cooling if it is too violent, and the solution of tin chloride formed is allowed to cool. The precipitate of purple oxide thus obtained is beautifully colored when it has been washed with boiling water.

There is a certain amount of galvanic action in amalgamating plates, both inside the battery and on the apron and sluice-plates. Some millmen attempt to increase the effect of this galvanic current by connecting the plates with electric wires. Too little attention has been given this subject to make it possible to state whether these attempts have resulted satisfactorily or not. The introduction of lead into amalgam causes it to become pasty, and results in loss of gold. The galvanic action of iron on the copper plates is greatly increased if the ore be first subjected to roasting. In those mills where electricity is employed, as an aid to amalgamation, the plates are connected with the negative pole, while the positive pole is formed by a plate of lead or iron dipping into the pulp. As a result, the mercury has a tendency to keep clean and bright, but the collection of base metals in the amalgam is promoted by the electric current, and a lower grade bullion is the consequence. This method should not be employed where the ore contains much lead, copper or zinc.

The Julian Process was invented at Johannesburg, South Africa. After chlorination of the ore in a barrel, mercury is added to the charge and the barrel again revolved. The result of this is to amalgamate the coarse gold in the ore, and to reduce the gold chloride. Chloride of mercury and metallic gold are formed, the latter amalgamating with the excess of mercury. The charge is then emptied out and passed over a set of amalgamated copper plates, on which the gold amalgam is partly retained. The tailing is then passed through a series of electrolytic cells each of which is provided with a bath of mercury at the bottom, while an electric current is passed through the water. In these cells, the compounds of gold and silver, soluble in the water, and all floured mercury and amalgam are supposed to be collected. The process has not come into extensive use, although it embodies some ingenious ideas, in taking advantage of certain well-known chemical reactions. The process is considered too complicated for general use, though it may be applied with success on certain unusual ores.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

BLAST FURNACE VS. REVERBERATORY.

THE EDITOR:

Sir—Mr. Neill's questions in reference to the comparative advantages of the blast furnace as compared with the reverberatory have reference, as I understand it, to the treatment of copper-bearing ores carrying more or less gold and silver. The questions and replies I give as follows:

1. On what should the choice of furnace type be principally based? Character of the ore, fuel, fluxes, building materials?

In the southwestern United States, as in New Mexico and Arizona, where oxidized ores of copper abound, these have been smelted directly to black copper in the blast furnace, producing a slag containing 1.5 to 2% Cu; but of late years, where sulphide ores have been available, matte smelting has been preferred, since the slag produced, carrying as little as 0.3 to 0.7% Cu, occasions less loss of copper. In smelting to black copper, some experiments made by Mr. J. D. Cooper of the Calumet and Hecla smelter, while in Arizona some years ago, have shown, that by the use of hard coal, it has been possible in the case of black-copper smelting, to bring down the percentage from the 2% mentioned above, to less than 1% in actual practice. However, these superficial ores are decreasing in quantity, and the smelting of them with sulphides is the prevailing practice.

We may say, therefore, that the ores which we have in view are sulphide ores carrying copper, and, in the case of pyrite smelting, such ores, carrying but little copper, but containing the precious metals, are those chiefly sought. These ores, as they come to the smelting works, are more or less finely comminuted, and, in treatment, their mechanical condition must be considered. Were the ore directly charged to the blast furnace, the force of the blast would cause a serious loss in flue-dust; whereas, in the reverberatory, the hearth is comparatively quiet, and, after charging, any dust caused by the dropping of the charge, soon settles. The reverberatory furnace does not burn off the sulphur as the blast furnace does, and hence, the ore going there must first be roasted. In this operation there is also a loss of dust, though to a much less degree than in the blast furnace. In the older practice of copper smelting in the blast furnace, it was customary to roast much of the ore in lump form, since it was then not affected by the blast, and, through the removal of the sulphur, it lessened the amount of the matte made. The practice, as we can see in pyrite smelting, is to diminish the amount of the fuel as much as possible, and to burn off in the blast furnace a large portion of the sulphur that the ore contains.

Sulphide ores, carrying iron with silica enough either in them or in the accompanying ore, to flux them, that is, self-fluxing ores, are favorable both for reverberatory and for blast-furnace treatment. Where the ore, however, is high in silica, the reverberatory, though it will work with quite silicious slag, has its limitations, whereas, by the addition of the required amount of limestone, the blast furnace can be run satisfactorily. It may be asked, why cannot the same thing be done in the case of the reverberatory? To this, one can say, so it can, but the difficulty is that these fluxes eat into the sides of the furnace. In this connection the blast furnace has an advantage in that, with its water-jacketed sides, operation is continuous, while, in the reverberatory it is necessary to stop periodically to patch or fettle the furnace, and, at longer intervals, to close it down in order to make radical repairs.

The percentage of fuel needed for either operation needs to be seriously considered. In the case of the reverberatory this has been brought down from 33 to 21% in recent practice at Anaconda. These differences are not at all such as are found in blast-furnace work, where the coke in the smelting of oxidized ore may be as much as 15%; while in pyrite smelting, as low as 2 to 3%, or even no fuel at all, has been used.

As regards the character of building materials, Mr. Neill has probably in mind the character of brick needed for building a reverberatory furnace. We have been accustomed to the use of the clay fire-brick, but practice is coming around to the extensive use of silica brick for the sides and roof of the furnace, and, as I have seen, for the bottom, also. This brick steadily expands in heating, so that cross-slits have to be made to allow for longitudinal expansion amounting to three inches in ten feet. Such brick is very durable when used in a furnace producing a silicious slag of 35 to 40% SiO_2, and resists the highest heat.

2. What are the comparative costs per ton of daily capacity of each type of furnace? In the case of the reverberatory, this cost should include the expense of the necessary roasting plant.

Referring to Hofman's 'Notes on the Metallurgy of Copper in Montana,' we may make a comparision between the cost of smelting in a 56 by 180 in. blast furnace and a reverberatory furnace with 20 by 50 ft. hearth dimensions.

Blast Furnace. 400 Tons of Charge Daily.

Labor (3 shifts)	$ 70.17
Fuel, 44 tons @ $7.50	330.00
Power for blast	48.00
Limestone, 25%, or 100 tons @ $0.50	50.00
	$498.17
300 tons ore @	$1.66
Briquetting fine	.10
Prime cost per ton	$1.76

Reverberatory Furnace. 112.5 Tons Daily.

Labor	$ 42.00
Fuel, 37 tons @ $4	148.00
Limestone, 4.5 tons @ $0.50	2.25
	$192.25
108 tons ore @	$1.78
Roasting	.35
Prime cost per ton	$2.13

The above results are for labor and materials only, but they serve to illustrate relative advantages. Recent practice at the Washoe plant of the Anaconda Copper Mining Co. will decrease these figures on each side. Taking again the available data, one may make an estimate for fuel and labor sufficient to give an idea of comparative results as follows:

Blast Furnace. 1600 Tons of Charge Daily.

Labor (3 shifts)	$ 120.00
Fuel, 160 tons @ $7	1,120.00
Power for blast @ $0.12 per ton charge	192.00
Limestone, 400 tons @ $0.50	200.00
	$1632.00
1200 tons ore @	$1.36
Briquetting fine	.10
Prime cost per ton	$1.46

Reverberatory Furnace. 275 Tons of Charge Daily.

Labor (3 shifts)	$ 42.00
Fuel, 56 tons @ $4	224.00
Limestone, 11 tons @ $0.50	5.50
	$271.50
266 tons ore @	$1.02
Roasting	.35
Prime cost per ton	$1.37

In the above figures it has not been attempted to determine actual costs, but only to reckon the variable constituent prime cost, leaving out fixed charges. Thus, while these figures enable us to institute comparisons, they are far from expressing the actual total cost.

3. What is the comparative space requirement for an equal tonnage?

Allowing that the space for storage will be the same per ton, whether the ore goes to one or other type of furnace, we shall find that a larger area is needed for the roasters and reverberatory furnaces together than for the blast furnace building, briquetting plant and power-house. Figuring on this basis, I have found for buildings, 58 sq. ft. of area needed for reverberatory treatment against 8.5 square feet for the blast-furnace plant, or nearly in the proportion of 7 to 1. It so happens that in the present practice of the plant the ratio of production is as 6 to 1; this is a curious coincidence.

4. What is the comparative cost of mechanical equipment for equal tonnage?

The ore intended for the reverberatories, under the conditions just given, is in the most favorable condition for roasting; containing, as it does, enough sulphur so that no extraneous fuel is needed for that operation. For such an ore, and to reduce the cost as low as 35c per ton, a mechanical furnace is required. The cost of such a mechanical equipment may be considered as fully offsetting that of the power plant needed for operating the blast furnace and the briquetting plant.

5 What are the comparative costs of power, labor, fuel and repairs?

Repairs, in the case of reverberatories, are a large item of expense as Mr. E. P. Mathewson has shown in your issue of March 24. In small furnaces some fettling is done after nearly every charge, while, in the largest, it is executed every month or six weeks. Another serious drawback to reverberatory smelting is that the sand bottom may come up, occasioning a loss of charge, and compelling the shutting-down of the furnace to dig out the old material and to make repairs. At the best, a large reverberatory must be cooled down every month or six weeks, after drawing off the slag and matte, and repaired by banking up the sides with sand or coarsely ground quartz rock. This cools down the furnace and delays operations. At least every six or eight months, radical repairs have to be made, which involve cooling down the furnace entirely, so that the workman may get in to make repairs. The arch, bridge, and sides of the furnace, at least near the fire-box, must be rebuilt. The blast furnace, on the other hand, with its fore-hearth, when in successful operation, needs but little repair. Even when the furnace is down, it can be cooled and its hearth or crucible speedily repaired. A fore-hearth, in most cases, may be made to last indefinitely, the trouble being rather that of filling up than of corrosion.

6. What are the comparative amounts of capital tied up in furnaces of each type, and how does this affect the cost per ton of daily capacity or of output?

Mr. E. P. Mathewson in the article already referred to, has given the costs of plant under both methods of treatment, in which he includes the concentrating plant. Were this excluded, the cost of plant would vary according to output. That is, a blast furnace with its building and equipment, and producing 1600 tons daily, would cost no more to erect than a 275-ton reverberatory furnace with the eight McDougall roasters needed to supply it with ore. If we accept this comparison, the ratio of cost, and of interest on that cost, are nearly as six to one. I recall an estimate of such a cost based upon daily output as being $400 per ton for a blast-furnace plant. Against this we would have $2400 as the cost of an equivalent reverberatory plant. This figured at 7% interest to 350 days' operation of the former and on 300 days of the latter (because of shut-downs for repairs) would make an additional cost in one case of 8c and in the second of 56c per ton.

7. What are the limiting necessities in the way of fuels for each type?

We are tied down practically to the use of coke in blast-furnace work. If the coalfields producing coking coal are near-by, then the smaller quantity of the more expensive coke offsets the larger amount of coal needed in reverberatory practice. Again, with non-coking coal near-by, the cheaper fuel has the advantage. Where the coalfields are distant the question of freight comes in, so that the ratio of cost between the coal and coke is less and in such cases is to be preferred. This has been brought out when considering the relative costs of the various grades of coal, where it can be shown that where the freight cost is high, the better-grade coal is the cheaper, in spite of the lower figures at which the lower-grade coals are offered.

8. What are the comparative losses in slag, dust, or middle products?

In the new reverberatories of Anaconda the charges are dropped into the furnace near the fire-box end of the hearth, and are there for the most part melted down, consequently the rest of the furnace for a distance of 50 to 75 ft. is a settler or fore-hearth, where a thorough separation is effected between the slag and the matte. As a result, the slag is but a fractional percentage higher than that of the blast furnaces of the same plant, and where a 16-ft. fore-hearth is used.

While there is no middle product in the regular operation of a reverberatory, it must not be forgotten that the extensive hearth becomes soaked up with matte, thus locking up values which are only recovered when an old hearth is broken out and a new one put in. This becomes a more serious matter in proportion to the amount of precious metals in the ore undergoing treatment. Such values, even when recovered by

smelting, owing to loss in slag, owing to expense of getting out the bottom, and of treatment, make an additional cost of $3 to $5 per ton, at least.

The flue-dust made by the blast furnace, even where the coarse ore is treated and the fine briquetted, is, in copper practice, another source of loss, since that product must be briquetted and re-smelted, thus undergoing double treatment. Besides this, such fine makes trouble in the furnace, occasioning accretions, raw ore at the tuyeres, and other troubles. Indeed, were it not for the assistance arising from briquetting, the losses would be much greater than they now are. In older blast-furnace practice, a 5 or 10% loss of flue-dust was not uncommon.

9. What are the defining limits of each type in regard to slag composition?

One hears and knows of high-silica slags such as those made at Mansfield, in Germany, carrying as much as 65% SiO_2, and of instances where, as in pyrite smelting, a low-grade matte is produced of 55% SiO_2. While such slags are often clean, they are viscous and slow-running, so that, for large output, a 40% silica slag is preferred. For a correspondingly liquid slag for reverberatory practice this limit of 40% should not be exceeded. One reads of slags, so silicious that they contain pieces of undecomposed quartz from the charge which pieces never have been melted, but have had their valuable metal extracted. Such slags have to be skimmed by the rabble, and are in no way suited to the conditions calling for a freely-flowing slag, which issues from the furnace as at Anaconda at skimming time at the rate of 5 tons per minute.

10. How do these differences in slag figure out in regard to slag composition?

In silver-lead smelting in the Rocky Mountain States, silica is estimated as costing 10c per unit or 20 lb. per ton to smelt. Hence, where the slag can be raised an additional 10%, as from 35 up to 45% SiO_2, it is equivalent to $1 saved in smelting. But, if at this regular percentage, the tonnage of the blast furnace drops off, it may cause a loss equivalent to this gain.

11. What method of charging do you advocate for a copper furnace assuming the atmosphere to be oxidizing?

Automatic charging does very well, crude as it appears to be, for the blast furnace, and, if necessary, it could be supplemented by a little hand-feeding where the furnace seems to need it. The older way was satisfactory where the amount of charge was small (100 tons or so), but for the large furnaces such methods are inadequate and expensive; so mechanical charging has been substituted. This consists in dumping into the furnace, direct from charge-cars or from buggies, sometimes as much as five tons at a time. It is to be understood, however, that these charges are added so as to keep the surface of the charge in the furnace as even as possible.

12. Would you bind, in some manner, all the fine for use in the blast furnace? Incidentally, what are the difficulties of treating fine ore in the blast furnace?

I should bind or briquette the fine by all means, especially, where a suitable binder is to be had. At Anaconda they are fortunate in having a slime or fine tailing resembling clay, which carries 2 to 4% copper and some silver, and which makes an excellent binder. In the practice at that place the fine ore and this binder are pugged and put through an end-cut briquetting machine, having an output of 840 tons of the mixture daily. It is charged moist to the blast furnace, not being dried at all. The briquetting is done with a force of nine men, including the foreman, and, hence, the cost per ton may be put at a low figure. Where, as is often necessary, a lime binder is used, the cost would be greater and the toughness of the briquette less. The evil resulting from an undue proportion of fine, comes from the choking of the furnace, the formation of crusts or accretions where this fine material adheres to the side walls, and the working down of fine ore through the charge until it appears at the tuyeres in an unmelted condition, introducing raw ore into the melting-zone of the furnace.

L. S. AUSTIN,

Michigan College of Mines,
Houghton, April 24, 1906.

THE GEOLOGICAL AGE OF THE EARTH AS COMPARED TO THE LIFE OF THE SUN.

The Editor:

Sir—In the April number of the 'Review of Reviews' there is an article on the age of the earth, which calls for this criticism. It appeals to a recent discovery regarding the apparent transmutation of radium into some other element, with the accompanying liberation of heat, as an explanation of the source of the sun's energy, related to the geological history of the earth. The writer, along with all the others who have written on the subject, overlooks the very apparent fact that the energy of the sun cannot be expended except on matter. Where there is no matter with one of the properties of matter, such as solid, liquid, or gas, there can be no loss of energy. If it were possible to expend energy on nothing, then O x Energy=O, so that energy is destroyed, which is contrary to the law of conservation of energy.

It may be argued that outside the earth's atmosphere, and in fact pervading all space, there is a fourth condition of matter without mass, which is called the ether, which serves the purpose of a medium of transmission for the sun's energy, and also of heat and light between the stars. On the earth the sun's energy is rendered sensible in terms of mass and temperature, so that where there is no mass the temperature must be absolute zero. This condition does not exist on the earth or in its atmosphere, but the temperatures at great altitudes, at the equator or elsewhere, show that the temperature of untenanted space is approximately absolute zero. How could it be otherwise? Heat being the effect of inter-atomic vibration, and there being no atoms to vibrate, the heat must be zero. That brings us back to the question of the loss of heat energy by the sun. It has all along been assumed that the sun radiates, or let us say loses, heat and energy equally in all directions. This is an absolute impossibility unless there is matter with mass at lower temperatures than the sun's to intercept each ray, or in other words, a solid mass of stars covering the entire sky. Even if each ray were intercepted if infinitely prolonged, the chances are in favor of it striking a bright star or sun as hot or hotter than our sun from which it would receive as much heat as it gave, and therefore lose nothing. If, therefore, the loss of energy by the sun is limited to matter with mass at lower temperature than its own, that loss will be a small portion of one per cent of what it would be according to all past teaching, by which it lost energy equally in all directions regardless of whether there was matter there to receive it or not. If the loss of energy is reduced in this manner, the time it would last is correspondingly increased, and the physicists and astronomers need not worry over the age of the earth or appeal to radium to make up the shortage.

The worst feature of this matter as regards science is that it shows that there are snobs in science as well as in other walks of life. Anything published or written by the bearer of a great name is spread broadcast at telegraph speed, while a patent fact sent in from an obscure writer will go to the waste-paper basket even if accompanied by stamps. For example, the substance of the above article as an explanation of the age of the earth as compared to the computed life of the sun was written and sent to several so-called scientific publications, and presumably destroyed, in spite of the fact that there is good sound reason in every statement. It is too much to expect that a beggar will pluck away the last of his rags, and stand exposed to the world, for are they not the badges of his profession? It is likewise too much to expect that an unsolicited criticism of an idea advanced by so great a name as Darwin should ever get past the waste basket.

HANDLING MEN.

THE EDITOR:

Sir—Through the medium of his article on 'Handling Men Underground,' appearing in your issue of March 3, Mr. R. B. Nickerson has precipitated a discussion which should be prolific of good results. I have read his contribution with much interest. In it he describes what may be considered the two extreme types of mining boss, neither of whom, to my mind, can be expected to secure the most desirable results, as has also been pointed out by Mr. Edward W. Ralph, under 'Discussion' in the issue of April 14.

This is one of the most important problems for the mine manager. He must select a superintendent or foreman in whom he places full confidence, and if a mistake is made in filling this important position, it may mean commercial failure, where success might otherwise have resulted. In the first place, before a man is fully competent to undertake the duties of the office of foreman he must have had his share of practical experience, such as will enable him to judge correctly the performances of the men working under him. It is a mistake, in my opinion, to place a tyrant in charge of men. An overbearing manner will not prove a satisfactory substitute for experience. In a single day the workmen will form a correct estimate of the capacity and character of their 'boss,' and will act accordingly. Even the most crafty foreman is not omnipotent, and the men will take advantage of his absence at each opportunity. Upon his unexpected approach, the signal is passed along, and although he may occasionally catch the idler, the net result of sneaking, espionage and underhanded methods is a loss of efficiency; the working force is disorganized, and the appearance of earnest activity is spasmodic; it is only a 'bluff.'

The antithesis of the spying foreman is he who fraternizes with the men, ever ready with a jest, and with the extended hand of good-fellowship. The men may speak of him as "a good man to work for," but they will usually take an unfair advantage of his leniency, almost as quickly as they will of a driving foreman, though possibly in a different spirit. They recognize in the easy foreman a friend, inclined to overlook shortcomings, and they will not fail, as a rule, to take their labors less seriously and earnestly than honest purpose should suggest. The crew is 'harmonious,' but it is also controlled by a spirit of leisurely effort; the laggard sets the pace for all. Put this same crew, or any one of them, on contract work and the difference in results is truly astonishing. Give the men an opportunity to display their skill and the latent force which lies in them, show a substantial appreciation of their work, and the pathway to satisfactory results is smoothed.

The foreman who is most successful is he who has had practical experience, who is a good judge of men and their work; who treats the men with firmness, divested of harshness, so that the men will respond promptly. Miners not only expect, but demand, just treatment from their employers, and the foreman who is firm, but just, who treats his men with decency, while maintaining his dignity, is the one who will accomplish the greatest economic, as well as the best social results, provided he is also competent to form a proper estimate of the individual and collective capacity of his men.

The foreman never ready to listen to a suggestion from those under his direction, or even to seek advice from them, is, if not a failure, at least not at his best. He may safely do both without loss of dignity or control. It has been demonstrated, not only in mines, but in industrial enterprises of entirely different character, that where the men are encouraged to use their brains as well as their hands, better results are always accomplished.

W. H. STORMS.

Berkeley, April 20, 1906.

Cements.—The term 'puzzolan cements' is applied to finely ground mixtures of slaked lime with certain argillo-calcareous materials. These added materials may be either natural products like the puzzolan, trass and sanitorin of the European cement trade, or basic slag from the blast furnace. In America natural puzzolanic materials have never been used, though they are known to exist at various points in the West. Slag, however, has been extensively used in the manufacture of slag cement. Slag cement, properly so-called, is the product obtained by pulverizing, without calcination, a mixture of granulated blast-furnace slag and slaked lime. This product, though in reality a member of the class of puzzolan cement, is often marketed as a portland cement in spite of the fact that it differs from portland cement in method of manufacture, ultimate and rational composition and properties. —Edwin C. Eckel.

Copper in Virginia.—The most noted copper region of Virginia is in the southwestern portion of the State in a belt of crystalline rocks passing through Floyd, Carroll and Grayson counties. The region is part of the eroded Blue Ridge upland marked by well-rounded summits and deeply-trenched streams, and is referred to as the Floyd-Carroll-Grayson plateau. The region was actively prospected in the early fifties and the rich secondary copper ores found beneath the gossan were boxed and shipped to Baltimore. During 1854-5 there were eight producing mines on the gossan lead; the aggregate amount of ore shipped for the six months from January 1855 to July 1855 being 1,454,363 lb. The ore averaged about 25% copper and at that time the metal was worth 26c per pound.—W. H. Weed and T. L. Watson in Economic Geology, Vol. 1.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

BLAST FURNACE VS. REVERBERATORY.

THE EDITOR:

Sir—Mr. Neill's questions in reference to the comparative advantages of the blast furnace as compared with the reverberatory have reference, as I understand it, to the treatment of copper-bearing ores carrying more or less gold and silver. The questions and replies I give as follows:

1. On what should the choice of furnace type be principally based? Character of the ore, fuel, fluxes, building materials?

In the southwestern United States, as in New Mexico and Arizona, where oxidized ores of copper abound, these have been smelted directly to black copper in the blast furnace, producing a slag containing 1.5 to 2% Cu; but of late years, where sulphide ores have been available, matte smelting has been preferred, since the slag produced, carrying as little as 0.3 to 0.7% Cu, occasions less loss of copper. In smelting to black copper, some experiments made by Mr. J. D. Cooper of the Calumet and Hecla smelter, while in Arizona some years ago, have shown, that by the use of hard coal, it has been possible in the case of black-copper smelting, to bring down the percentage from the 2% mentioned above, to less than 1% in actual practice. However, these superficial ores are decreasing in quantity, and the smelting of them with sulphides is the prevailing practice.

We may say, therefore, that the ores which we have in view are sulphide ores carrying copper, and, in the case of pyrite smelting, such ores, carrying but little copper, but containing the precious metals, are those chiefly sought. These ores, as they come to the smelting works, are more or less finely comminuted, and, in treatment, their mechanical condition must be considered. Were the ore directly charged to the blast furnace, the force of the blast would cause a serious loss in flue-dust; whereas, in the reverberatory, the hearth is comparatively quiet, and, after charging, any dust caused by the dropping of the charge, soon settles. The reverberatory furnace does not burn off the sulphur as the blast furnace does, and hence, the ore going there must first be roasted. In this operation there is also a loss of dust, though to a much less degree than in the blast furnace. In the older practice of copper smelting in the blast furnace, it was customary to roast much of the ore in lump form, since it was then not affected by the blast, and, through the removal of the sulphur, it lessened the amount of the matte made. The practice, as we can see in pyrite smelting, is to diminish the amount of the fuel as much as possible, and to burn off in the blast furnace a large portion of the sulphur that the ore contains.

Sulphide ores, carrying iron with silica enough either in them or in the accompanying ore, to flux them, that is, self-fluxing ores, are favorable both for reverberatory and for blast-furnace treatment. Where the ore, however, is high in silica, the reverberatory, though it will work with quite silicious slag, has its limitations, whereas, by the addition of the required amount of limestone, the blast furnace can be run satisfactorily. It may be asked, why cannot the same thing be done in the case of the reverberatory? To this, one can say, so it can, but the difficulty is that these fluxes eat into the sides of the furnace. In this connection the blast furnace has an advantage in that, with its water-jacketed sides, operation is continuous, while, in the reverberatory it is necessary to stop periodically to patch or fettle the furnace, and, at longer intervals, to close it down in order to make radical repairs.

The percentage of fuel needed for either operation needs to be seriously considered. In the case of the reverberatory this has been brought down from 33 to 21% in recent practice at Anaconda. These differences are not at all such as are found in blast-furnace work, where the coke in the smelting of oxidized ore may be as much as 15%; while in pyrite smelting, as low as 2 to 3%, or even no fuel at all, has been used.

As regards the character of building materials, Mr. Neill has probably in mind the character of brick needed for building a reverberatory furnace. We have been accustomed to the use of the clay fire-brick, but practice is coming around to the extensive use of silica brick for the sides and roof of the furnace, and, as I have seen, for the bottom, also. This brick steadily expands in heating, so that cross-slits have to be made to allow for longitudinal expansion amounting to three inches in ten feet. Such brick is very durable when used in a furnace producing a silicious slag of 35 to 40% SiO_2, and resists the highest heat.

2. What are the comparative costs per ton of daily capacity of each type of furnace? In the case of the reverberatory, this cost should include the expense of the necessary roasting plant.

Referring to Hofman's 'Notes on the Metallurgy of Copper in Montana,' we may make a comparision between the cost of smelting in a 56 by 180 in. blast furnace and a reverberatory furnace with 20 by 50 ft. hearth dimensions.

Blast Furnace. 400 Tons of Charge Daily.

Labor (3 shifts)	$ 70.17
Fuel, 44 tons @ $7.50	330.00
Power for blast	48.00
Limestone, 25%, or 100 tons @ $0.50	50.00
	$498.17
300 tons ore @	$1.66
Briquetting fine	.10
Prime cost per ton	$1.76

Reverberatory Furnace. 112.5 Tons Daily.

Labor	$ 42.00
Fuel, 37 tons @ $4	148.00
Limestone, 4.5 tons @ $0.50	2.25
	$192.25
108 tons ore @	$1.78
Roasting	.35
Prime cost per ton	$2.13

The above results are for labor and materials only, but they serve to illustrate relative advantages. Recent practice at the Washoe plant of the Anaconda Copper Mining Co. will decrease these figures on each side. Taking again the available data, one may make an estimate for fuel and labor sufficient to give an idea of comparative results as follows:

Blast Furnace. 1600 Tons of Charge Daily.

Labor (3 shifts)	$ 120.00
Fuel, 160 tons @ $7	1,120.00
Power for blast @ $0.12 per ton charge	192.00
Limestone, 400 tons @ $0.50	200.00
	$1632.00
1200 tons ore @	$1.36
Briquetting fine	.10
Prime cost per ton	$1.46

Reverberatory Furnace. 275 Tons of Charge Daily.

Labor (3 shifts)	$ 42.00
Fuel, 56 tons @ $4	224.00
Limestone, 11 tons @ $0.50	5.50
	$271.50
266 tons ore @	$1.02
Roasting	.35
Prime cost per ton	$1.37

In the above figures it has not been attempted to determine actual costs, but only to reckon the variable constituent prime cost, leaving out fixed charges. Thus, while these figures enable us to institute comparisons, they are far from expressing the actual total cost.

3. What is the comparative space requirement for an equal tonnage?

Allowing that the space for storage will be the same per ton, whether the ore goes to one or other type of furnace, we shall find that a larger area is needed for the roasters and reverberatory furnaces together than for the blast furnace building, briquetting plant and power-house. Figuring on this basis, I have found for buildings, 58 sq. ft. of area needed for reverberatory treatment against 8.5 square feet for the blast-furnace plant, or nearly in the proportion of 7 to 1. It so happens that in the present practice of the plant the ratio of production is as 6 to 1; this is a curious coincidence.

4. What is the comparative cost of mechanical equipment for equal tonnage?

The ore intended for the reverberatories, under the conditions just given, is in the most favorable condition for roasting; containing, as it does, enough sulphur so that no extraneous fuel is needed for that operation. For such an ore, and to reduce the cost as low as 35c per ton, a mechanical furnace is required. The cost of such a mechanical equipment may be considered as fully offsetting that of the power plant needed for operating the blast furnace and the briquetting plant.

5 What are the comparative costs of power, labor, fuel and repairs?

Repairs, in the case of reverberatories, are a large item of expense as Mr. E. P. Mathewson has shown in your issue of March 24. In small furnaces some fettling is done after nearly every charge, while, in the largest, it is executed every month or six weeks. Another serious drawback to reverberatory smelting is that the sand bottom may come up, occasioning a loss of charge, and compelling the shutting-down of the furnace to dig out the old material and to make repairs. At the best, a large reverberatory must be cooled down every month or six weeks, after drawing off the slag and matte, and repaired by banking up the sides with sand or coarsely ground quartz rock. This cools down the furnace and delays operations. At least every six or eight months, radical repairs have to be made, which involve cooling down the furnace entirely, so that the workman may get in to make repairs. The arch, bridge, and sides of the furnace, at least near the fire-box, must be rebuilt. The blast furnace, on the other hand, with its fore-hearth, when in successful operation, needs but little repair. Even when the furnace is down, it can be cooled and its hearth or crucible speedily repaired. A fore-hearth, in most cases, may be made to last indefinitely, the trouble being rather that of filling up than of corrosion.

6. What are the comparative amounts of capital tied up in furnaces of each type, and how does this affect the cost per ton of daily capacity or of output?

Mr. E. P. Mathewson in the article already referred to, has given the costs of plant under both methods of treatment, in which he includes the concentrating plant. Were this excluded, the cost of plant would vary according to output. That is, a blast furnace with its building and equipment, and producing 1600 tons daily, would cost no more to erect than a 275-ton reverberatory furnace with the eight McDougall roasters needed to supply it with ore. If we accept this comparison, the ratio of cost, and of interest on that cost, are nearly as six to one. I recall an estimate of such a cost based upon daily output as being $400 per ton for a blast-furnace plant. Against this we would have $2400 as the cost of an equivalent reverberatory plant. This figured at 7% interest to 350 days' operation of the former and on 300 days of the latter (because of shut-downs for repairs) would make an additional cost in one case of 8c and in the second of 56c per ton.

7. What are the limiting necessities in the way of fuels for each type?

We are tied down practically to the use of coke in blast-furnace work. If the coalfields producing coking coal are near-by, then the smaller quantity of the more expensive coke offsets the larger amount of coal needed in reverberatory practice. Again, with non-coking coal near-by, the cheaper fuel has the advantage. Where the coalfields are distant the question of freight comes in, so that the ratio of cost between the coal and coke is less and in such cases is to be preferred. This has been brought out when considering the relative costs of the various grades of coal, where it can be shown that where the freight cost is high, the better-grade coal is the cheaper, in spite of the lower figures at which the lower-grade coals are offered.

8. What are the comparative losses in slag, dust, or middle products?

In the new reverberatories of Anaconda the charges are dropped into the furnace near the fire-box end of the hearth, and are there for the most part melted down, consequently the rest of the furnace for a distance of 50 to 75 ft. is a settler or fore-hearth, where a thorough separation is effected between the slag and the matte. As a result, the slag is but a fractional percentage higher than that of the blast furnaces of the same plant, and where a 16-ft. fore-hearth is used.

While there is no middle product in the regular operation of a reverberatory, it must not be forgotten that the extensive hearth becomes soaked up with matte, thus locking up values which are only recovered when an old hearth is broken out and a new one put in. This becomes a more serious matter in proportion to the amount of precious metals in the ore undergoing treatment. Such values, even when recovered by

smelting, owing to loss in slag, owing to expense of getting out the bottom, and of treatment, make an additional cost of $3 to $5 per ton, at least.

The flue-dust made by the blast furnace, even where the coarse ore is treated and the fine briquetted, is, in copper practice, another source of loss, since that product must be briquetted and re-smelted, thus undergoing double treatment. Besides this, such fine makes trouble in the furnace, occasioning accretions, raw ore at the tuyeres, and other troubles. Indeed, were it not for the assistance arising from briquetting, the losses would be much greater than they now are. In older blast-furnace practice, a 5 or 10% loss of flue-dust was not uncommon.

9. What are the defining limits of each type in regard to slag composition?

One hears and knows of high-silica slags such as those made at Mansfield, in Germany, carrying as much as 65 SiO_2, and of instances where, as in pyrite smelting, a low-grade matte is produced of 55% SiO_2. While such slags are often clean, they are viscous and slow-running, so that, for large output, a 40% silica slag is preferred. For a correspondingly liquid slag for reverberatory practice this limit of 40% should not be exceeded. One reads of slags, so silicious that they contain pieces of undecomposed quartz from the charge which pieces never have been melted, but have had their valuable metal extracted. Such slags have to be skimmed by the rabble, and are in no way suited to the conditions calling for a freely-flowing slag, which issues from the furnace as at Anaconda at skimming time at the rate of 5 tons per minute.

10. How do these differences in slag figure out in regard to slag composition?

In silver-lead smelting in the Rocky Mountain States, silica is estimated as costing 10c per unit or 20 lb. per ton to smelt. Hence, where the slag can be raised an additional 10%, as from 35 up to 45% SiO_2, it is equivalent to $1 saved in smelting. But, if at this regular percentage, the tonnage of the blast furnace drops off, it may cause a loss equivalent to this gain.

11. What method of charging do you advocate for a copper furnace assuming the atmosphere to be oxidizing?

Automatic charging does very well, crude as it appears to be, for the blast furnace, and, if necessary, it could be supplemented by a little hand-feeding where the furnace seems to need it. The older way was satisfactory where the amount of charge was small (100 tons or so), but for the large furnaces such methods are inadequate and expensive; so mechanical charging has been substituted. This consists in dumping into the furnace, direct from charge-cars or from buggies, sometimes as much as five tons at a time. It is to be understood, however, that these charges are added so as to keep the surface of the charge in the furnace as even as possible.

12. Would you bind, in some manner, all the fine for use in the blast furnace? Incidentally, what are the difficulties of treating fine ore in the blast furnace?

I should bind or briquette the fine by all means, especially, where a suitable binder is to be had. At Anaconda they are fortunate in having a slime or fine tailing resembling clay, which carries 2 to 4% copper and some silver, and which makes an excellent binder. In the practice at that place the fine ore and this binder are pugged and put through an end-cut briquetting machine, having an output of 840 tons of the mixture daily. It is charged moist to the blast furnace, not being dried at all. The briquetting is done with a force of nine men, including the foreman, and, hence, the cost per ton may be put at a low figure. Where, as is often necessary, a lime binder is used, the cost would be greater and the toughness of the briquette less. The evil resulting from an undue proportion of fine, comes from the choking of the furnace, the formation of crusts or accretions where this fine material adheres to the side walls, and the working down of fine ore through the charge until it appears at the tuyeres in an unmelted condition, introducing raw ore into the melting-zone of the furnace.

Michigan College of Mines,
Houghton, April 24, 1906.

THE GEOLOGICAL AGE OF THE EARTH AS COMPARED TO THE LIFE OF THE SUN.

The Editor:

Sir—In the April number of the 'Review of Reviews' there is an article on the age of the earth, which calls for this criticism. It appeals to a recent discovery regarding the apparent transmutation of radium into some other element, with the accompanying liberation of heat, as an explanation of the source of the sun's energy, related to the geological history of the earth. The writer, along with all the others who have written on the subject, overlooks the very apparent fact that the energy of the sun cannot be expended except on matter. Where there is no matter with one of the properties of matter, such as solid, liquid, or gas, there can be no loss of energy. If it were possible to expend energy on nothing, then O x Energy=O, so that energy is destroyed, which is contrary to the law of conservation of energy.

It may be argued that outside the earth's atmosphere, and in fact pervading all space, there is a fourth condition of matter without mass, which is called the ether, which serves the purpose of a medium of transmission for the sun's energy, and also of heat and light between the stars. On the earth the sun's energy is rendered sensible in terms of mass and temperature, so that where there is no mass the temperature must be absolute zero. This condition does not exist on the earth or in its atmosphere, but the temperatures at great altitudes, at the equator or elsewhere, show that the temperature of untenanted space is approximately absolute zero. How could it be otherwise? Heat being the effect of inter-atomic vibration, and there being no atoms to vibrate, the heat must be zero. That brings us back to the question of the loss of heat energy by the sun. It has all along been assumed that the sun radiates, or let us say loses, heat and energy equally in all directions. This is an absolute impossibility unless there is matter with mass at lower temperatures than the sun's to intercept each ray, or in other words, a solid mass of stars covering the entire sky. Even if each ray were intercepted if infinitely prolonged, the chances are in favor of it striking a bright star or sun as hot or hotter than our sun from which it would receive as much heat as it gave, and therefore lose nothing. If, therefore, the loss of energy by the sun is limited to matter with mass at lower temperature than its own, that loss will be a small portion of one per cent of what it would be according to all past teaching, by which it lost energy equally in all directions regardless of whether there was matter there to receive it or not. If the loss of energy is reduced in this manner, the time it would last is correspondingly increased, and the physicists and astronomers need not worry over the age of the earth or appeal to radium to make up the shortage.

The worst feature of this matter as regards science is that it shows that there are snobs in science as well as in other walks of life. Anything published or written by the bearer of a great name is spread broadcast at telegraph speed, while a patent fact sent in from an obscure writer will go to the waste-paper basket even if accompanied by stamps. For example, the substance of the above article as an explanation of the age of the earth as compared to the computed life of the sun was written and sent to several so-called scientific publications, and presumably destroyed, in spite of the fact that there is good sound reason in every statement. It is too much to expect that a beggar will pluck away the last of his rags, and stand exposed to the world, for are they not the badges of his profession? It is likewise too much to expect that an unsolicited criticism of an idea advanced by so great a name as Darwin should ever get past the waste basket.

HANDLING MEN.

THE EDITOR:

Sir—Through the medium of his article on 'Handling Men Underground,' appearing in your issue of March 3, Mr. R. B. Nickerson has precipitated a discussion which should be prolific of good results. I have read his contribution with much interest. In it he describes what may be considered the two extreme types of mining boss, neither of whom, to my mind, can be expected to secure the most desirable results, as has also been pointed out by Mr. Edward W. Ralph, under 'Discussion' in the issue of April 14.

This is one of the most important problems for the mine manager. He must select a superintendent or foreman in whom he places full confidence, and if a mistake is made in filling this important position, it may mean commercial failure, where success might otherwise have resulted. In the first place, before a man is fully competent to undertake the duties of the office of foreman he must have had his share of practical experience, such as will enable him to judge correctly the performances of the men working under him. It is a mistake, in my opinion, to place a tyrant in charge of men. An overbearing manner will not prove a satisfactory substitute for experience. In a single day the workmen will form a correct estimate of the capacity and character of their 'boss,' and will act accordingly. Even the most crafty foreman is not omnipotent, and the men will take advantage of his absence at each opportunity. Upon his unexpected approach, the signal is passed along, and although he may occasionally catch the idler, the net result of sneaking, espionage and underhanded methods is a loss of efficiency; the working force is disorganized, and the appearance of earnest activity is spasmodic; it is only a 'bluff.'

The antithesis of the spying foreman is he who fraternizes with the men, ever ready with a jest, and with the extended hand of good-fellowship. The men may speak of him as "a good man to work for," but they will usually take an unfair advantage of his leniency, almost as quickly as they will of a driving foreman, though possibly in a different spirit. They recognize in the easy foreman a friend, inclined to overlook shortcomings, and they will not fail, as a rule, to take their labors less seriously and earnestly than honest purpose should suggest. The crew is 'harmonious,' but it is also controlled by a spirit of leisurely effort; the laggard sets the pace for all. Put this same crew, or any one of them, on contract work and the difference in results is truly astonishing. Give the men an opportunity to display their skill and the latent force which lies in them, show a substantial appreciation of their work, and the pathway to satisfactory results is smoothed.

The foreman who is most successful is he who has had practical experience, who is a good judge of men and their work; who treats the men with firmness, divested of harshness, so that the men will respond promptly. Miners not only expect, but demand, just treatment from their employers, and the foreman who is firm, but just, who treats his men with decency, while maintaining his dignity, is the one who will accomplish the greatest economic, as well as the best social results, provided he is also competent to form a proper estimate of the individual and collective capacity of his men.

The foreman never ready to listen to a suggestion from those under his direction, or even to seek advice from them, is, if not a failure, at least not at his best. He may safely do both without loss of dignity or control. It has been demonstrated, not only in mines, but in industrial enterprises of entirely different character, that where the men are encouraged to use their brains as well as their hands, better results are always accomplished.

Special Correspondence.

LONDON, April 18.

According to a statement recently issued, the Orsk Goldfields, Ltd., has a nominal capital of £600,000 in £1 shares. Of these 500,000 shares, credited with 15s paid up on each share, have been issued to the Siberian Proprietary Mines, Ltd., the vendor, in payment for the lease and options referred to below. The whole of these 500,000 shares have now been paid up in full, thus providing £125,000 for working capital, including rent and general expenses of the company. The remaining 100,000 shares are being held in reserve, and provision will be made thereout for the final payment for the properties and for further plant. The chairman of the company is Sir J. West Ridgeway; there are two continental directors and Heyman Orkin is the managing director.

The Orsk goldfields are situate in the Russian steppes in the Province of Orenburg about 250 miles south of Tscheliabinsk, on the Siberian railway, and about 200 miles northeast of Actubin, on the Orenburg-Tashkend railway. The primary object of the Company's operations is the development and exploitation of a valuable network of veins, which are being already worked in a primitive manner, and a systematic prospecting of the property with a view to further discoveries. The area to which these operations will extend is, in the aggregate, upwards of 16,000 acres. Mining operations on a limited scale have been in progress within certain narrow limits for the past six years, about 40,000 tons of quartz having been treated (according to the books of the present owners) for a yield of about 50,000 oz. of bullion (25 dwt. per ton), valued at 67s. 6d. per oz., which is equal to £168,750 or 84s per ton of ore crushed. This does not include any recovery from tailing, over 35,000 tons of which have yet to be dealt with. The profits accruing during these operations are represented as having amounted to £80,000, the mills running only 300 working days in the year, being closed down on Sundays and holidays. The profits for 1905 alone are said to have been about £20,000. Out of their total profits the owners have spent £20,000 for mills, machinery, (including one excellent 120 h. p. engine), buildings, telephone installation, etc., all of which are in good order. The ore is extracted under a system of tribute. The tributers used to pay, until the end of last year, about £5 per day, but now they pay £3 per day, for the use of each Chilean mill; that is, they are charged about 6s. per ton of ore crushed, and they receive the bullion from the three middle plates only. They are bound to sell the bullion to the owners of the mill at a specified price. The bullion from the first and fifth plates remains the property of the owners of the property, as well as the gold which is in the tailing.

The six Chilean mills now in operation are unable to cope with the present production. The existing reduction plant is to be doubled, after which it is estimated the profits will be increased by about £50,000 per annum, bringing up the total to £320,000 per annum. Labor, both skilled and unskilled, is stated by Messrs. John Taylor and Sons, who have lately been employed by the Siberian Proprietary Mines Ltd., in making a report on the property and surrounding conditions, to be plentiful, good, and very cheap. According, also, to their report, living in the district is cheap, and can be made comfortable. The climate is healthy and the people are well disposed. The Novgorodov reef, averaging 4 ft. in width, has furnished by far the largest proportion of the gold as yet taken out, and has averaged over a period of five years, according to the books of the late owners, 84s per ton. The assay of the Sofonofski reef, averaging in width 1 ft. 4 in., gave an average of 21 dwt. or 85s. per ton (excluding one assay of 7 oz. 18 dwt. or £32 per ton) and the Miaski reef, with an average width of 3 ft., gave 16 dwt. or 65s per ton.

Amongst the prospectuses issued this month, one of the most important is that of The North Cerro Muriano Copper Mines Ltd., formed under the auspices of John Taylor & Sons. The capital is £250,000 of which £75,000 is working capital. The property consists of an area of about 387 acres situate about 10 miles from the city of Cordova, Spain, and adjacent to the Cerro Muriano mines. According to a report by Mr. Alexander Hill, six distinct lodes have been traced upon the surface of the property to be acquired and there is every probability that they will be found to be of similar value to that now being worked in the Cerro Muriano mines. The prospectus states that the prospective value of the lodes is enhanced by the existence of extensive ancient workings, as in the case of the Cerro Muriano lode, where payable ore has been already developed below the old workings.

The report of Charlotte Plains Consolidated Gold Mines Ltd., (Deep lead area, Victoria, Australia) for 1905 states that the work of putting in drifts from the jump-ups, for the purpose of draining the wash-dirt, has been going on steadily, and some rich prospects of gold have been struck. As mentioned in the cable of March 19, a large body of black sand has now been met with, assaying up to 30 oz. of gold per fathom. The returns so far taken from these drifts, which, it is pointed out, are only in the shallow ground as yet, and from which no rich return was expected, are 184 oz. of gold from 275 fathoms of wash-dirt. A piece of quartz richly studded with gold was obtained in the sluice of the Charlotte Plains, and the assistant Government Geologist is of opinion that the reef or leader from which it became detached must be close at hand. The indications therefore point to exceptionally rich pockets and to the wash-dirt so far opened out being all more or less gold-bearing.

A report is issued from another 'deep lead' property in Victoria. The secretary of Loddon Valley Goldfields Ltd. states that the erection of the new auxiliary jump, completed in November last, which enables pumping to be carried on notwithstanding stoppages for repairs, has had a marked effect in the reduction of the water, the reports from the mine showing that the average pressure, which at the end of October last indicated 558 lb. per sq. in. at the bottom of the bores, has now been reduced to 27¾ lb. In anticipation of the wash being entered at an early date, the new shaft necessary for handling it has been sunk closer to the lead and timbered to about 450 ft. It is now being carried down to 535 ft., to allow of the effective drainage of the lowest parts of the lead. In view of the satisfactory position as evidenced by the rapid reduction of the water-pressure, it was decided to create and issue 30,000 new shares of £1 each to provide additional funds. The shareholders are reminded that Mr. Waldemar Lindgren, of the U. S. Geological Survey, in his report, which was circulated amongst them, estimates the gold contents of the property at £1,700,000, and possibly considerably more, and anticipates that the wash can be treated expeditiously and inexpensively when once the water is under control.

The Golden Horseshoe Estates Co. Ltd. (Kalgoorlie) held their eighth annual meeting last week. The capital is £1.500,000 in £5 shares. The net profit for 1905 was £305,604. The total ore treated at the mine and shipped to smelters during the year amounted to 223,035 tons, producing 196,680 ounces of bullion, containing 106,152 oz. fine gold, the extraction, excluding gold from re-treatment of tailing, being 88.91 per cent. The total cost per ton, including development, together with an allowance of 15 per cent for depreciation on plant, etc., amounted to £1.12s.5d., as against £2.5s.9d. for 1904. The chairman, Sir John Purcell, called the special attention of the meeting to the matter of ore reserves. He explained for the benefit of those shareholders who are not conversant with mining technicalities that he excluded entirely from consideration the quantity of ore estimated to be within a certain area, but not ready for stoping, and dealt only with ore reserves actually in sight and blocked out on three sides. This when worked out makes 931,307 tons, containing 700,352 oz. fine gold, of the value of nearl three millions sterling. He thought that this, of itself, must be regarded as satisfactory and encouraging, seeing that the ore actually in sight and ready for stoping is sufficient to supply their 150 stamps at the rate of 20,000 tons per month for a period of four years to come. Referring to the grade of the ore the chairman mentioned that 139,977 tons now considered of no value are included in the ore reserves. This had been done in order to allow for the necessary inclusion of waste from walls and intrusions of mineralised country, and the proceeding is based upon the assumption that, in the course of stoping, eight inches of each wall will come away with the ore. On this basis of working, the actual grade of ore to be treated in the current year will approximate closely to the estimated grade of the blocked out reserves. The chairman said the manager reported that in 1904 the allowance in question was not fully taken into consideration. They were of opinion that the policy of working the stopes to their full width and breaking, together with the ore, some eight or more inches of the walls is a correct one. The last 50 stamps were erected in order that lower grade ore might be profitably treated. In 1904 the average grade per ton was 22 dwt. In 1905 the average grade was somethin_ over 15 dwt. Thus in 1905 a far lower grade of ore was treated, with good profit, than was dealt with in 1904. The extraction from the ore treated in 1905 was a little less than in 1904. This is accounted for by the fact that in 1905 only 8,139 tons of ore were sent to the smelter, as against 18,059 so dealt with in 1904. On the subject of working costs, the chairman was glad to say that during the year 1905 they had succeeded in effecting a considerable reduction. The total working cost per ton of 2,240 lb., excluding development, was £1.8. 7 for 1905, as against £1.19 0 for 1904, or a drop of 10s5d. per ton. This year, by means of the improvement in the plant, the tonnage would be brought up to 20,000 tons per month, and the extraction maintained. Referring to recent "calumnious statements, unfounded insinuations and covert suggestions" affecting the mine, the chairman said: "We are told, forsooth, that the bottom is out of the mine—that we have but two years of ore reserves—and the like. Well, with the knowledge we have of our general manager over a period of years, we fully and confidently credit him when he assures us that, working them out on a most conservative basis, our ore reserves, developed and actually in sight, are sufficient to maintain the present output for four years."

The following from last night's 'Globe' is worth quoting: Writing from Johannesburg to a Liverpool friend, under date March 16, Mr. Rudyard Kipling gives in characteristic fashion his impressions of "Chinese slavery." Heading the letter, "This from the tortured Transvaal—Winston holding the tongs afar off," he writes: "It's a poor situation that the Book can't find a text for, and the Minor Prophets are full of 'em. When in doubt consult the Apocrypha. Things are bewilderingly bad here. A whole colony standing up to be shot at by their own people is an awful sight. I've been seeking the Chinese slaves in their loathsome dungeons. It looks rather better grub than in barracks, and I couldn't see any bars and padlocks. One downtrodden serf came in with the materials for a spread for some friends—wheaten bread at sixpence a loaf, corned beef and vinegar. He spent 2s6d. There's no restriction on good workmen going about as they please, and—well, the whole agitation at home makes me sick when I think of English cottages, sanitation, and food. If only the fools would come out and see for their crazy selves. But they won't."

MELBOURNE, March 3.

The new year has begun with mining in a decidedly flourishing condition at Bendigo and with depression at Ballarat. Bendigo is indeed a marvellous district. Geologically, of course, its saddle formations have invested it with a world-wide interest. To Victorians, however, the great question is the area in which these formations exist, and what is their vertical depth and how deep are these saddles gold-bearing. Today the New Chum has proved the presence of a gold-bearing saddle at 4,200 ft., and the Victoria Quartz, also on the New Chum line, has proved golden quartz to exist below 4,000 ft. The point of interest yet to be proved is the extent of these formations, and both companies are at work continuing their shafts to the depth of the center-country winze so as to open up levels and define the dimensions of the saddle as well as its quality. From 3,000 to 4,000 ft. is a depth that very few mines indeed have attained. Consequently it is hardly fair to take the results achieved below 3,000 ft. as a criterion of what the field is likely to do at that depth; still, there is the case of the New Chum Railway which at 3,000 ft. worked a saddle which gave shareholders profits amounting to £100,000. Mr. George Lansell is also breaking profitable ore in his No. 180 mine at 3,310 ft. Thus two out of the six or eight mines down below 3,000 ft. have got gold in payable quantities. Of equal, if not greater interest, is the possibility of the horizontal extension of the gold field. Up to the present time, Bendigo has won from within an area two miles wide and eight miles long, £82,000,000 worth of gold. In the middle of two miles are 13 anticlinal folds of the country. Really, however, the bulk of the mining work has been done on three main lines known as the New Chum, Garden Gully and the Hustler's. Not one of these lodes, however, has failed to produce gold at different times, but the superior richness exposed by the main lines has, as stated, led to their receiving the greatest attention. Mr. E. J. Dunn, the geological authority on the region, who out of pure love for his work has gone into harness again as director of the Victorian Geological Survey, is so profoundly impressed with the developments at depth, the extension of the field both north and south and the better prospects obtained on the side lines from the main anticlines, that he now deliberately applies the term 'illimitable' to the gold resources of Bendigo. It is not enthusiasm which makes him speak in that way. He does so with a full realization of the responsibility of his words and he says: "If the enterprise of

50 years is examined, it bears only the smallest relation to the possibility of the field as indicated by the actual work done. Knowing the gold that has been got, one is quite justified in predicting that there are centuries of work ahead of Bendigo. The great strength of Bendigo lies in the fact that its base is so well established that the industry will go on automatically. The companies have so many shafts and so many working faces being pushed ahead that although one mine may decline so many more will come in view that interest in the field will always be sustained. In Bendigo today it has become a matter of so many miners put on and so many ounces of gold won, that is, of course, providing the labor is employed with discretion." To this testimony can be added that of Mr. F. Greenard, mining inspector of Western Australia, who, after spending ten days on the field, has left it full of enthusiasm for its possibilities, for its winding plants, for the good ventilation, for the capacity of its mining men and for the intense loyalty of its people to the district. This last is the most gratifying feature to Victorians. We do not want outsiders to go to Bendigo because, as a rule, they come and spend money, lose it and then blame the field. The Great Southern is an example of this. When the claims were abandoned by John Bull after splendid sinking and but little driving on the saddles, it was taken up by the local company, which now appears to be on the high way to success. In conclusion, it may be said that the February returns of the field are the highest for many years, thus giving weight to Mr. Dunn's panegyric.

Turning from local to inter-state matters, the great event of the week has been the flotation of the Hampden-Cloncurry copper mines in north Queensland. The property is away in the extreme north of Australia, some 200 miles south of the Gulf of Carpentaria and was taken up originally by some of the old Broken Hill people, notably, Messrs. Knox, Schlapp, William Orr, and J. Harvey Patterson. It was intended to float a company with a capital of a million strong to build a railway from Normanton via Cloncurry to the mine. Negotiations, however, were blocked by the labor party in the Queensland Parliament. That party at the time was determined to prevent the construction of any privately-owned railways in the State. Coats, the great English cotton manufacturing firm, were understood to be prepared to finance the venture. However, with the rejection of the railway scheme the project fell through. For six years the company has had to wait for capital. The collapse of the Chillagoe mines helped to keep the field back, but the development of the O. K. and the Mt. Holloy mines, together with the high price of copper, has re-directed attention to the resources of the locality. The flotation provides for the creation of a company of 200,000 shares of £1 each, of which 100,000 go to the holders in the present company, and are fully paid up. They, in their turn, pay an underwriting commission of 25,000 shares to Messrs. W. L. Baillien, Lionel Robinson, Bewick Moreing & Co., and their associates for underwriting an issue of 50,000 shares at £1 each to provide working capital. In addition, 50,000 shares go into reserve. The company is thus being floated under very strong financial support. It may be added that prior to the deal being carried through, the underwriters got the call of more than half the interest held by the holders on the original company in the 100,000 shares; but this fact has not come out. Reports on the property are to the effect that copper worth £1,000,000 sterling is 'in sight' down to the water-level. A part of the promoters' scheme is to build a tramway from the Government line to the mine, but this project is to form part of a second flotation.

TORONTO, April 28.

Though the snow in northern Ontario is still deep in the woods, it has disappeared sufficiently along the river banks and in exposed localities to allow of active prospecting work, and thousands of treasure-seekers are busy in the Cobalt and adjoining districts. The rush is largely to the north of the Cobalt area proper, where a wider field presents itself, as so much of the township of Coleman and the adjacent townships of Bucke and Lorraine have been staked out, that the opportunities of the prospector near the scene of present productive development have greatly decreased. Hence the movement of the genuine prospectors—as distinguished from those who expect to make money by stock speculation, gambling in real estate, or catering to the wants of the miners,—is largely to the region further north.

The rush in this direction has ben stimulated by reports of the finding of rich gold-bearing quartz in Playfair township, some 80 miles north of Cobalt. Charles Hurd, who had been one of the party engaged in the survey of the township, brought back to Haileybury samples of quartz assaying $17,000 per ton from a deposit in the center of the township. Veins of quartz are reported to occur frequently in the locality, and in the northwest of the township cobalt bloom has been discovered, from which there is reason to infer that the other metals of the cobalt rocks may also exist. Large numbers from Haileybury and New Liskeard, as well as new arrivals, are trying their fortunes in this untrodden field. The Temiskaming and Northern Ontario railway has been built to within about 30 miles of Playfair, and the "end of the steel" is becoming more and more the objective point of the prospector. With the building of the road further north, which will be continued until it effects a junction with the new Grand Trunk Pacific near Lake Abitibi, every station will become more or less of a mining center and point of distribution from which prospecting parties will strike off into the woods and obtain supplies, so that even if the productiveness of the mines in the immediate vicinity of Cobalt continues, that town will lose much of its importance as a distributing focus and "jumping-off place." At present, however, building is going forward with great energy—whole streets of hotels, boarding-houses and business places are being run up, and speculation in town lots has run wild. The latest development is a real estate proposition put forth by a big syndicate of Toronto and Winnipeg capitalists who have secured 640 acres of land about 2½ miles north of the town, and laid it out as the North Cobalt townsite, in the hope that the business interests of Cobalt may eventually be centered there. Of course the settlers and investors in the present town are highly indignant over this widely advertised project, claiming that North Cobalt has no right to its name.

According to all the principles of sanitary science, Cobalt ought long before this to have been devastated by typhoid or some contagious disease on account of the defective sanitary arrangements, but so far no such outbreak has taken place, and, in fact, a recent inspection by an official of the provincial Board of Health showed the health of the place to be exceptionally good. Stricter methods, however, are being enforced by the recently organized municipal body, and the drinking of unboiled water is prohibited until a supply of uncontaminated water can be secured.

At the Foster mine a rich vein has been struck, five inches wide, in which free silver largely predominates. At the Nova Scotia mine a vein has been found carrying 8,000 oz. per ton. Near Clear Lake, about a mile from the townsite, a prospector named Charron has discovered a rich vein about five inches wide. The University or Glendinning mine, the property of George Glendinning, W. J. Blair and H. L. Kerr, has been shipping ore since November last, the returns from the output amounting to about $100,000. The shaft has been sunk to about 80 ft., and there are two drifts on the 70-ft. level, one having been worked for 90 and the other for 50 ft. The vein averages 15 in. wide, and is worked overhand, the waste rock raising the level of the drift instead of having to be hauled to the surface and dumped. A Rochester syndicate has secured the McKinley and Darragh mine, which will probably be joint-stocked and placed on the market.

Many smelter projects have been brought forward, but the mine owners are now for the most part less interested in that question, since a company including some of the leading operators undertook to start a refinery at Hamilton which will account for the cobalt, arsenic and nickel contents of the ore, as well as the silver.

The Government mining bill is now before the Ontario legislature. The principal feature is the substitution of a uniform method for the obtaining of mining rights for the various and conflicting systems in vogue under the present law. It proposes that all prospectors must take out a license, paying $10 annually. On making an actual discovery of valuable minerals they must stake out the claim and record it in the record office of the mining division. Each claim is to be a square of 20 chains to a side. The claim is subject to inspection, and if found satisfactory the prospector is required to do 180 days' work, distributed over three years, unless he chooses to complete it in less time. He may then buy the land, paying $3 per acre in surveyed localities or $2.50 per acre in unsurveyed territory, and acquires thenceforth an indefeasible title. Some objection has been raised to the latter provision, many contending that working conditions should be permanently imposed to prevent the evil of land being held unworked for an indefinite period by speculators, but the measure appears likely to go through substantially as introduced. In cases where, owing to depth of soil or overlying rock, the mineral does not outcrop, and trenching, sinking a shaft or boring with the diamond-drill are necessary to make an actual discovery, a working permit may be issued, giving the holder exclusive possession for six months on condition of his working the property five days each week.

The bill is to be supplemented with another measure fixing the taxation of mining lands, and providing for the giving of bonuses by the Province to smelters. No royalties on output will be imposed, but mining lands will be taxed eight cents per acre in unorganized districts, and five cents per acre in municipalities. Out of the funds accruing from this tax and the fees, etc., imposed under the Mining Act, $60,000 per year will be set apart for five years for bonusing smelters according to output on the following scale: nickel, six cents; copper, one cent; arsenic, one-half cent; and cobalt, five cents per pound. The limit of the amount to be paid to the refiners each year is $25,000 for nickel, $15,000 for copper, and $10,000 each for cobalt and arsenic, and should the output call for an amount exceeding appropriation, a division pro rata will be made.

Prof. Miller, the Provincial geologist, starts for the Gillies timber limit, just south of the Cobalt area, next week, accompanied by several assistants, to make a thorough survey of the mineralized section of the limit and a contour map. This is understood to be a preliminary step to the contemplated working of the deposits as a government undertaking.

The Canadian Geological Survey is sending out a large number of field parties to make geological and mineralogical investigations during the season. A. E. Barlow and party will trace the extension of the silver-bearing formation of the Cobalt area eastward into Quebec Province. Some important researches will be prosecuted in the Yukon and British Columbia. In the Yukon Territory, R. G. McConnell and J. Keele will make an estimate of the gold remaining in the gravels of Bonanza and Hunker creeks, near Dawson, and Mr. Cairns will study the silver deposits of Windy Arm. In British Columbia, R. W. Brock, W. H. Boyd and G. A. Young will complete an exhaustive study of the Rossland camp, and conclude their investigations in the Lardeau district. C. Camsell will explore the mining area of the Similkameen district, and Mr. Leach will investigate the prospects of coal and other minerals in the Bulkley valley. E. D. Ingall will visit all the leading iron districts to obtain material for a bulletin on the iron resources of Canada.

Frank Cochrane, Minister of Lands and Mines, announced in the legislature of the 23d inst. that anthracite had been found in New Ontario, specimens of which had been submitted to him. He declined to enter into particulars or specify the locality, but it is believed that the specimens came from deposits on the Albany river, which forms the dividing line on the north between Ontario and Manitoba.

JOHANNESBURG, March 26.

No greater proof could be found for the assertion that the troubles of the Transvaal are principally political, than the annual reports of the mines. This is the harvest time of the year for mining reports. At almost every meeting reference is made to the uncertainty occasioned by the Liberals, and the feeling of dismay occasioned by such men as Winston Churchill in his speeches in the House of Commons. In the majority of cases, the year ending December 31, 1905, was a very successful one, but the chairmen of companies warn stockholders of the probable dangers of 1906.

The annual report of the Rand Mines, Ltd., is always anticipated as one of the events of the year in mining circles. Mr. L. Reyersbach, presiding at the annual meeting held in Johannesburg last week, gave a masterly review of operations for 1905. The profits for the year are £1,786,179. The average working costs, calculated over the whole of the tonnage milled was 23s. 3.133d. per ton. There were 1145 stamps at work during the year, crushing 2,023,239 tons, from which 850,503 oz. (valued at £3,572,133) were extracted. The yield per ton for the year was 35s., 3.732d. Compared with 1904, an average of 135 additional stamps were in operation, and the tonnage milled was increased by 311,491 tons. The value of the yield per ton shows a decrease of 1s., 2.885d., and working costs an increase of 1s., 4.627d. per ton, the total decrease in profit per ton being 2s., 7.512d. The decrease in the yield is due in most cases to ordinary fluctuations in the character of the reefs. The enhanced working costs are attributed to a considerable increase in the amount of development done; also to an increase in hand-stoping, 37.6 per cent having been broken by hand, as against 7 per cent for the previous year, and finally to the effect which Chinese labor has had on the working costs,

owing to the laborers being unaccustomed to mining work.

The report shows that tube-mills are "going strong." Seven are now running on the subsidiary companies of the Rand mines; sixteen are being erected or are under order. It is thought that a further 1s., 3d. per ton milled will be extracted by the use of tube-mills.

The chairman of the Rand Mines, Ltd., shows conclusively how fatal the scheme of "white unskilled labor" would be for the Rand. If these mines are to be worked at a profit, under present conditions, it is absolutely necessary to have an abundant supply of Chinese or Kaffir laborers. Mr. Reyersbach shows that it is not the wealthy man who will suffer most through the diminution of the labor supply by unfriendly legislation. He can afford to wait, or he can apply his wealth to investments in other parts of the world. It is the artisan, the clerk, the engineer who will suffer most; the man who has invested his hard-earned savings in the mines. Some people think that the huge wealth of the Rand Mines, Ltd., is owned by a few millionaires. The annual report shows that the assets of the Rand Mines, Ltd., are owned by no less than 2,919 registered shareholders, a great number of whom live on the continent of Europe.

At the annual meeting of the Witwatersrand Township, Estate and Finance Corporation, the chairman referred to the prevailing depression due to present political conditions, by stating that the "gaunt specter of starvation stalks the streets day and night." We can almost feel the chilling effect of his shadow on our people, and for each man who comes under the influence of his ominous presence, there is enrolled a bitter and determined opponent of the dictatorial and blighting policy of the present British government.

SALT LAKE CITY, April 29.

Work has begun in the rebuilding of the branch railway between the mines of Alta and Sandy. The old horse-tram running from Wasatch to Alta is to be replaced by a standard road. Steam or electricity will be used as motive power.

The Columbus Consolidated at Alta has recently made connection with the main fissure on the 300-ft. level. The ore is identical with that on the level above, and no time will be lost in determining the extent of the new find.

Orders for two battery engines, to be used in the equipment of the Utah Copper Co.'s mill at Garfield, have been placed with the Allis-Chalmers Co., Milwaukee. Two more of the same type will be installed as the work progresses. Upon its completion the plant will supply 6000 h. p., and the cost of construction will probably exceed $100,000. It is estimated that the structural steel used in the various parts of the plant will amount to 12,000 tons.

One of the most important of recent strikes is that made lately by the Ohio Copper Co. at Bingham. In the latest stope on the 500-ft. level there has been uncovered four feet of native copper ore. The metal occurs in thin sheets, some of them $\frac{1}{16}$ in. wide and a foot long.

Developments at the Bingham Central, at Bingham, continue to be of an encouraging nature. The recent strike in the Jackling tunnel has exposed a fine body of ore of the same nature as the usual copper ore of the camp. In the Whitley tunnel a good grade of argentiferous lead ore is now being extracted.

The last shipment from the Big Fourteen property, of Stateline, has aroused considerable interest. The car was divided into first and second-grade lots. The first grade carried 475.5 oz. silver and 5.9 oz. gold, netting about $400 per ton, while the second class went 124 oz. silver and 1.4 oz. gold, bringing it close to $100 per ton. Two sacks of selected ore showing assays of 4,137.7 oz. silver and 46.34 oz. gold, and having a market value of $3,600 per ton, were also in the lot. The mine is being worked by lessees.

The past week proved to be a record breaker for the Tintic district. With twenty-one mines contributing, a total of 232 carloads of ore was shipped during the week.

An official report states that the California and Comstock mines, at Park City, have consolidated and will henceforth be operated under one management. Work will be started at once to bring these mines again into the list of producers.

The management of the Ohio Copper Co., at Bingham, is developing the lead ore deposits in its Winnemuck mine, and in a crosscut on the 140-ft. level has encountered three feet of high-grade ore.

In the development of the Harrington and Hickory mine of the Majestic holdings in Beaver county, large bodies of ore have been encountered. The company has been making irregular shipments to Salt Lake smelters during the past few months, but it is expected that operations will be carried on upon a much larger scale this summer.

It is generally believed that F. Augustus Heinze has secured control of the Bingham Consolidated. The option that Mr. Heinze secured when he acquired control of a large block of stock expired Friday, and it is believed that this option was taken up. The investigation of Bingham by Mr. Heinze has aroused unusual interest, and the outcome of the big deal is eagerly awaited.

On Friday the management of the Utah Apex company, of Bingham, let the contract for the new tramway which will extend from the Andy tunnel to a spur of the Copper Belt railroad. The contract was awarded to the Trenton Iron Works. The tram, known as the Bleichert tramway, will cost in the neighborhood of $40,000, and will make a span of 2200 feet. With a capacity of 200 tons per day the output of the mine will be greatly increased and the expense reduced to the minimum.

The new concentrating plant of the Godiva mine at Eureka, which was recently completed, has proven a great success, and is now in regular commission. The new mill has a capacity of 150 tons per day.

The last shipment from the New York, at Park City, carried 20% lead, 125 oz. silver and $1.80 gold.

Upon the completion of the big plant at Garfield the Boston Consolidated, of Bingham, will double its present tonnage. In the main stope seventeen sets have been erected and are still in ore. The daily output could easily be increased to 400 tons, but at present the smelters can handle only 200, and in the meanwhile a great reserve is being stored up.

BUTTE, April 23.

Among the forty or more new mining companies organized within the past six months to explore and develop copper properties in Butte, about a dozen of them are active, with good prospects of developing new producing mines. The Butte-Milwaukee Copper Co. expects to begin mining on the Pollock within a month or six weeks. The Pollock is a developed property which has yielded a lot of good ore in the past, and the company has four other claims on the same vein. They are the Colonel Sellers, Bird, Box Car, Florence and Stonewall. For 4,000 ft. the company owns ground on the Pollock vein. All the claims are patented. In addition to the Butte properties the company owns seven claims in Argenta mining district. John F. Cowan, of Butte, is president of the Butte-Milwaukee.

The Butte Copper Mining Co. is another active company among the new ones. The water has been pumped from the workings of the Trifle and in a few days mining will be resumed. The two Anselmo mines and the two Emmett mines will be opened later. The mines of the company lie just west of the Gagnon of the Amalgamated company and the Silver King of the Coran company, and the veins of the two latter mines pass through the new company's ground. The company expects to be able to ship ore from the old workings of the mines within a few months.

The East Butte Co. has completed its main three-compartment shaft to a depth of 350 ft., and is now sinking from that point. The shaft will be sunk at the rate of about 100 ft. per month and when the 500-ft. point is reached a crosscut will be started north and south through the entire width of the company's ground, while at the same time sinking will continue. It is the intention to put the shaft down to 1,200 ft. The lessees in the other shafts of the company are hoisting 200 tons of ore daily, of which 50 tons is first class, and is shipped to the Washoe smelter, while the remainder is treated at the company's concentrator in Butte. The 25 per cent royalties paid by the lessees is sufficient to meet the expense of development and improvements being made and is increasing the treasury reserve at the same time. The net earnings for April will aggregate $40,000.

The Butte Hill Copper Mining Co. has acquired 11 claims in the northern part of the district on the North Star lode, comprising about 173 acres. A shaft has been sunk to a depth of 135 feet, and is going down at the rate of four ft. per day. There is a fine vein showing in the shaft, the ore assaying for a width of four feet 30 oz. silver and a fraction over one per cent copper per ton. James Higgins, for many years one of Marcus Daly's superintendents, is president of the company, and Maurice Eisenberg is vice-president. Mr. Eisenberg is also vice-president of the Butte Copper and Zinc Co.

The Butte & Bacorn property, which is sinking its main shaft on the Colleen Bawn, is also on the North Star lead.

The Raven Mining Co. has opened the north Snoozer vein, and have 'in sight' about 150,000 tons of ore. Development continues on both veins on the 1200 and 1500 ft. levels, in the course of which the company is taking out nearly 100 tons of ore daily.

The Columbus-Butte Mining Co. appears to be in financial straits and has appealed to the stockholders to put up 2 cents a share on their stock to keep up the work on its mine. The company has been running behind ever since it started work, but the directors have been advancing money and taking stock in order to keep up the work. They announce now, however, that they have reached their limit.

The Pennsylvania mine of the Boston & Montana Co. was shut down for several days the past week because of the inability of the company to get timbers.

The name of the Butte & London Copper Co. has been changed to the Butte & London Copper Development Co. The change was made at the request of the London members of the board of directors, so as to indicate that the company is an exploration concern and is not yet engaged in mining copper. A statement, filed with the county clerk at Butte, shows that the company has $407,101 in the treasury and $30,000 worth of machinery on hand, and is the owner of the Greendale placer claim, on which it is sinking, and which it values at $5,000,000. The shaft of the Greendale has reached a depth of 250 ft., and is in rock in which a vein capping has been cut.

The North East Butte Copper Mining Co. has been incorporated with a capitalization of $1,000,000, by Butte and Oklahoma men. The Calumet and Butte Development Co., under the laws of Arizona, has been incorporated by Michigan men from Calumet and Hancock. A. M. MacKenzie, of Hancock, is in charge of the operations of the company at Butte.

The Butte Commercial Copper Mining and Development Co., the Butte Central Copper and Smelting Co., and the North Butte Mountain Copper Co., are among the latest companies incorporated, mostly by Butte men.

The West Butte Mining Co. has taken over half a dozen claims under option, in addition to the purchase of the Columbia, on which the original capitalization was based. It now controls the Columbia, Excelsior, Saturn, Vanderbilt, Henrietta, Donegal, Mint, Montrose and Flagstaff. The claims are to be developed by sinking the main shaft on the Columbia, now 140 ft. deep, to a depth of 1,200 feet.

It is stated on good authority that F. Augustus Heinze, who has secured control of the Bingham mines in Utah, is associated with J. A. Coram in the American Consolidated Copper Co., and that the latter's plans have been completely changed. The intention now is, so it is stated, to take in not only the Davis properties in Butte, but also the Bingham property, the Montana Coal and Coke, the Smokehouse Co. and Coram's California company. The promoters of the new company say that within a reasonable time after its complete organization it will be able to produce 100,000,000 pounds of copper yearly. Mr. Coram and Mr. Heinze have been in Butte for several weeks. Mr. Heinze has also become interested again in British Columbia. He has taken an option on 40 claims, mostly copper, along the line of the Grand Trunk Pacific railroad, the amount involved being $5,000,000. He is also interested in a project to build a smelter in the new Cobalt district, to cost $750,000. A site, consisting of 670 acres, has been secured for the smelter near Haileybury.

In March the Butte Coalition Co. produced 2,750,000 pounds of copper. The Butte Copper Exploration Co. is making good progress in sinking on the Six O'Clock group. The work has averaged more than five feet per day, and it is expected to reach a depth of 1,000 ft. by September.

Tin From Straits Settlements.—Consul-General Wilber furnishes from Singapore the statistics of tin exports from the Straits Settlements to the United States as follows: The total shipments of tin from the Straits Settlements for 1905 amounted to 63,710 tons, 18,905 tons going direct to the United States, 35,294 tons to England, and 9,511 tons to continental Europe. A small falling off in exports to the United States was caused by the high rates of exchange and by the advance in freight rates during October, November, and December by the New York shipping conference. The shipments to England the past two years materially increased, while those to the Continent gained gradually during the past four years. Many indirect shipments for the United States go from Singapore to England and the Continent which if shipped direct would materially increase the declared exports of tin to America from this region and cause more return cargoes of merchandise.

MINING SUMMARY

CALIFORNIA.

INYO COUNTY.

(Special Correspondence.):—Patrick Clark, of Spokane, has ordered a complete hoisting plant, operated by gasoline, for the shaft on the Copper Blue claim of the Furnace Creek Copper Co., in Death Valley, California. James Porter reports that the shaft is down 100 ft. and that the bottom is all in 30% ore—malachite and copper glance. It has been decided to sink the shaft 500 ft. and to crosscut at the 250 ft. level. Dennis Clark, vice president of the company, says they expect to have a smelter next summer.

Spokane, April 14th.

SAN BERNARDINO COUNTY.

As illustrating the dangers to those strange to the desert region, Peter Wilson has been taken to Needles to be treated for dementia. While Wilson was unloading machinery at Vontrigger, the new mining camp between Goffs and Manvel in the eastern part of this county, he wandered away and for three days roamed over the sand dunes, in all that time having no water or food. When found he was partially clad, his shoes and stockings were gone and his feet were bleeding from several lacerations received on the jagged rocks. This is the third man who has wandered away in the sand dunes in this manner within the past two weeks, though the first two did not fare so badly as Wilson.

COLORADO.

SAN JUAN COUNTY.

The Silver Lake mill, three miles from Silverton, was totally destroyed by fire at 4 o'clock on the morning of the 20th inst. The loss is estimated at $250,000, fully insured. The fire was doubtless of incendiary origin, as when the watchman discovered the blaze, which started in the office of the mill, and called for assistance, the hose was found cut, making headway against the flames impossible. But for this the fire could have been easily subdued.

The Silver Lake is the property of the Guggenheim smelter trust and was formerly owned by E. G. Stoiber. The capacity of the mill was 300 tons per day. There were 150 men working there at the time of the fire. No other buildings were damaged. It is thought rebuilding will begin as soon as possible.

NEVADA.

CHURCHILL COUNTY.

Surface rock that carries a high percentage of copper, a fair percentage silver, and a trace of gold has been found in Bliss canyon in the Jackson range. The discovery was made by J. Winkler who has staked out claims in the vicinity. Assays of the rock brought into Winnemucca by Winkler show 27.8% copper, 7.2 oz. silver, and a trace of gold. He will begin development this spring. Jackson mountains are about 65 miles from Winnemucca and have long been regarded as an excellent mining field. The advent of the Western Pacific will hasten the development of that region which is rich in high and low-grade ore. The present survey of the Western Pacific passes within a few miles of Jackson mountains and will make the shipping of ore profitable, where at present it is almost out of the question except in the case of high-grade rock.

The company shaft of the Manhattan Nevada Gold Mines owning the Georgey group at Central, is down 77 ft. The shaft was sunk through the vein, which pitched at an angle of 60°, and the bottom of the shaft is not yet through the ore.

A stamp mill has been erected just off the Georgey ground, and the Milling company obtained permission to sink a well on the Manhattan Nevada Gold Mines Company's property. A site was selected in the lowest portion of the property, near the mill, and the well started. Before they had obtained a depth of ten feet, ore was struck, and at the water level, about 60 ft., good milling ore encountered. The mill people are now negotiating with the owners of the Georgey group to get a contract for the handling of the ore from the well. Enough high-grade ore taken from the Manhattan Nevada Gold Mines can be furnished to keep the mill running.

LINCOLN COUNTY.

(Special Correspondence).—President Ripley, of the Santa Fe railroad, says that the Searchlight-Barnwell railroad will be completed within three months.—A new engine and pump have been ordered for the Santa Fe mine, which has been handicapped with a large flow of water, and preparations will be made to handle 200,000 gallons per day.— The Searchlight Mining & Milling Co. has struck ore in the east drift of the 250 ft. level. This ore is impregnated with coarse gold.— The Cyrus Noble Extension is doing systematic trenching to locate the exact position of the ledges of the adjacent property before determining the best position to sink the main shaft. This company has secured two more fractional claims.— The Superintendent of the Big Six Mining Co. is to install hoisting and pumping machinery. This company has struck a large flow of water at the 240 ft. level, which greatly interferes with further operations until adequate machinery is installed. The Cyrus Noble is forging to the front as one of Searchlight's best producers. All work is being rushed to its fullest capacity, especially with the underground work where drifting to the north is progressing to determine the extent of this ledge. Regardless of the heavy expense this company has been put to by the many new improvements in building and machinery, a dividend will shortly be declared.—An accidental discovery has been made at the Pompeii mine. The barrels into which water has been pumped direct from the shaft were found to contain several inches of sediment that by assay was found to carry thousands of dollars per ton thus showing that this mine is no exception to the rule of the district, that rich ores lie below the water level. A new electric pump is to be installed at this mine with a daily capacity of 500,000 gallons.

The cyanide plant of the Duplex Company is completed. The 18,000 tons of tailing of this company it is estimated will be handled at a cost of 50c per ton.— In El Dorado district the new hoist of the Venus is now on the ground and development will continue.— Ore is now being taken out of the Mountain Group in many different places, and a great deal of it is being sacked and prepared for shipping. The Rand shaft is all in ore. The developments in general at El Dorado canyon are surpassing the expectations of the owners, and according to present indications this district should give an excellent account of itself.

Searchlight, April 8, 1906.

(Special Correspondence).—The effect of the recent disaster in San Francisco has been felt in the Searchlight district to a certain extent, yet the wheels of progress did not stop, nor will the loss be felt to any exceeding extent, as Searchlight had little or no securities on the San Francisco exchange. Contributions to the stricken city were sent immediately, amounting to $1,085.—Grant Bros., railroad contractors, who have the contract for building the railroad from Manvel to Searchlight, have agreed to complete the road in 90 days, and are rushing work.—Another company operating within the town limits is the Nevada-Searchlight. This new company has acquired the mineral rights under both the Grand Central and the Arizona townsites, which are adjacent to the main portion of Searchlight.—The Buster group of five claims is held by Dawson & McKenzie under a working bond. These claims lie in the Nob Hill district. Mr. Allen, who will remain in charge of development, states that it is the intention of the company to start on the main vein. Several hundred feet of depth can be secured with such a tunnel.—The Quartette mine has opened up the orebody on the 900-ft. level, demonstrating that this mine has ore at that depth. The Bay State shaft that this company is sinking west of the principal workings is being rushed, and as soon as water is secured in this shaft the 20 new stamps now on the ground will be added to the 20 now in operation.

El Dorado District:—Reports from the Venus show constant improvement as work progresses. Some of the ore runs into the thousands; the ore-shoot is large and contains an average of $30 per ton. With cheaper railroad facilities this district will make many shipments of excellent ore.

Searchlight, April 24.

NYE COUNTY.

(Special Correspondence):—With the connection now being made between this camp and the Clark R. R. where we are to have a Station (No. 73), prospectors and mine owners here are jubilant, as it is evident we will now have an outlet for our ore. Only the destruction by last month's storms in Meadow Valley, Wash., between Las Vegas and Caliente, has prevented our station's earlier completion. The citizens here are building a large road leveler which is to be dragged forth and back between here and the station 12 miles distant, by 12 mules, until we have a good road, clear of rocks, brush, and hummocks and making a straight line, broad and level, over which to run a line of automobiles.

Since my last letter several prospects have been sold. Mr. Lake sold five claims for $2,500. Wm. W. Smith sold a group for $2,500. Boller, West & Co. sold three locations, just opened up on an eight foot vein. These sales were for cash except the last mentioned, which went for $1,000 cash, balance in stock, so it is evident there is something of promise in this part of Nevada also. This district is certain to come to the front after a time but it has been, up to date, completely isolated. Thomas & Co. will put in a mill this summer. Swain & Co., Colorado people, are figuring on a custom mill and cyanide plant, having abundance of water. This company is preparing to do business, as they have some as fair prospects as any in the district.—Parties are coming in looking for business openings, a new hotel among other things, and a Salt Lake branch store.—It will be possibly two weeks from this date until we can announce the completion of the road to Station 73, by which time our auto road will be completed, and then Johnnie will come to the front as an ore producer. The veins of this camp are large and attract the attention of mining men who see them. With the improved conditions we expect to do business.

Johnnie, April 21.

J. A. Kirby, general manager of the Montana-Tonopah Mining Co., has made public the quarterly report of his company for the months of January, February and March of this year. During the quarter 3,061 ft. of development and exploration work was done. On the first level 100 ft. were crosscut, and high-grade ore was found. On the second level the miners drifted 269 ft. into the vein, and cut several shoots of shipping ore, which will be developed. On the third level crosscuts have been met with satisfactory results, according to the report. Drifting east and west from the crosscut on the fourth level, the company raised 30 ft. on the vein in ore. Some of the drifting has been on good ore. On the fifth, which is the lowest level, drifting has been done east and west on the veins. In the east drift the company expects to cut an orebody inside of 50 ft.

Shipping ore is being stopped on all levels, it is stated, and several shoots of first-class ore on different levels have been neglected because of the limited hoisting capacity. During the past three months 2,638 mine cars of shipping ore; 1,151 cars of mill ore, and 13,442 cars of waste were hoisted. A new steel gallows frame has been erected, and will be in use in a few days, and a new hoist is expected in the near future.

The Consolidated Manhattan Gold Mining Co. at East Manhattan has a vein which outcrops boldly. The superintendent states that the ledge is fully 150 ft. wide. Pannings have been made at different points on the outcrop with good results. The company is developing this property by a tunnel on the Blue Bird claim, and, it is the intention to continue this tunnel opening up all ledges which traverse this hill. The face of the tunnel is in ore of low grade.

WASHOE COUNTY.

Recently a party examining the old Harris mine, to get knowledge of a group of claims adjoining it, made a valuable discovery. The vein was uncovered a few days previously by a blast made by the foreman. Mr. Stevens and Mr. Seibert knew that they had uncovered a good ledge, which was but one of the incidents in the plan of development as laid out for the mine, and examination of the ledge itself was not made. While a tour was being made through the tunnel the new ledge was carefully examined. There, plainly in view, was seen free gold. It was a sudden revelation and reminded one of the times when Edward Harris, owner of the mine, used to pound out by hand and mortar, thousands of dollars from rock knocked off the ledges with hammer and pick, with never a dollar's worth of machinery on the ground. Every mine in the district is making unusual progress and one discovery succeeds another in striking frequency. Within the last month astonishing headway has been made in this camp. The Rocky Hill extension has uncovered three of the ledges of the famous Rocky Hill mine. The Galena Hill property made a strike of rich galena which set the district agog.

The Willow Creek people, Mr. Clapp, superintendent, have uncovered a four-foot ledge of solid argentiferous galena, and now comes the discovery of this phenomenal ledge in the Harris. Such is the story of Washoe. Much prospecting is being done and new locations are being made. Among the new moves in the camp is the incorporation of the Harris Extension property. The Harris extension Company has taken eight claims adjoining the Harris mine. The incorporators of the Harris Extension are holders in the Rocky Hill, the Rocky Hill Extension and the Harris mines.

Nulty and Cocking have transferred their holdings in

the vicinity of the Rocky Hill mine to J. M. Fulton and associates. The price is $30,000. The property is a group of claims traversed by several dykes and ledges. Little development work has been done, but sufficient to show that the property is valuable.

WHITE PINE COUNTY.

A two-foot ledge of solid argentiferous galena, assaying 70% lead, was discovered last week by Bud Gallaher, three miles north of McGill's ranch on Duck creek. The ledge outcrops on the surface for 500 ft. Sixteen claims have been located in the vicinity of the strike, and prospectors are giving the district a more thorough examination than it has ever received before. The new discovery is 17 miles northeast of Ely, and the Nevada Northern will pass within two miles of it.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence):—At the Mountain Boy, in driving on the old workings, 30 sacks of ore were taken out the week ending April 14, which sampled $1100 per ton.—In the Ben Hur on the 300 ft. level, drifts have been driven 150 ft. on the pay shoot, from the crosscut. Small streaks of ore were encountered in driving and stoping that were rich in gold, and silver sulphide. A part of the stope above the 300 ft. level has been opened up to within 20 ft. of the 230 ft. level, but this seems to have no connection with the two ore shoots above. A winze is being sunk on the pay shoot below the 300 ft. level.—In the Copper Key a drift is being driven southward from No. 2 tunnel to get under the pay shoot developed on the level above. The face is in quartz. The difference of elevation between No. 2 level and the lowest point ore was found above is 210 ft.—In the Protection Fraction, a seam of coal was discovered two years ago within the city limits of Republic. A bond has been given with the right to mine, and men are now employed opening the prospect. About three feet of coal is in sight.

(Special Correspondence).—Fourteen carloads of ore were shipped in April from the Pearl Consolidated mine, but the grade was low. On the bottom, level ground is being prepared for stoping 165 ft. north of the shaft. A sample from the back assayed $12.20, and a muck sample, from the ore after it was broken down, ran $12.45 per ton. A crosscut started from the south drift on this level has not reached the hanging wall. There is an immense quantity of low-grade ore in the Lone Pine workings, and also exposed on the vein which runs 3000 ft. through the Pearl and Surprise claims, but it will all remain valueless until a method can be found suitable for its treatment at a low figure. The latest from the Lone Pine crosscut is an assay of $13.30 per ton.

Republic, April 28.

OKANOGAN COUNTY.

(Special Correspondence).—Operations on a larger scale than heretofore are to begin on the Leadville group of thirteen claims on Palmer mountain. A. S. Hickey, who was sent out from Columbus, Ohio, eighteen months ago, bonded the property in January, 1905, and last January took up the bond and paid $30,000, and a company has been organized for development. The principal claim is the Leadville, which has an average width of five feet, and has been partly developed by a shaft 160 ft. deep and a tunnel now in 565 ft. Three separate vein systems are traceable on the group, the principal vein on the Leadville being an extension of the Pinnacle, from which a large tonnage was formerly treated at the Black Bear mill, and some pockets of ore rich in gold were extracted. A 14-ft. vein traverses the Galena and Galena Fraction claims, the ore assaying $7.50 per ton, principally gold. The Denver City has a vein opened in five different places, showing an average width of three feet of gold ore. All of the veins carry some galena and a little silver. On the Leadville 80-ft. level a drift was run 70 ft., showing the vein four or five feet wide, the ore assaying $100 per ton. The company has arranged to spend $50,000 for development before ordering machinery. It is expected the company will acquire the right of way through one of the Pinnacle tunnels, drive 1,000 ft. on the Leadville vein and incidentally prospect others on the group. On the Galena a tunnel has been driven 100 ft., which will be pushed 200 ft. further to crosscut the vein at a depth of 300 ft.. The claims of this group have been prospected by John Judge, the original owner, for 19 years.

The tunnel on the Q. S. mine has advanced 900 ft. and crossed 78 ft. of the main vein, the ore averaging $10 per ton in copper and gold. Of 55 assays, 36 ran over $40, and 19 ran $13 per ton. Several other samples were lower. This vein crops from 100 to 300 ft. wide. The tunnel cuts the footwall at a depth of 600 ft. For a considerable length the cropping forms a perpendicular face, rising 150 to 200 ft. above the surface. This property is owned by the Q. S. Gold Mining and Smelting Co. A. M. Dewey is president and general manager. F. Moritz, formerly in charge of the Belle mine, in the Coeur d'Alene, for Finch and Campbell, of Spokane, Wash., is superintendent. The Q. S. group consists of a solid block of claims 4500 ft. long and 3600 ft. wide. Six men are employed, and the force will be increased as soon as room can be made for the men. The old log buildings of the camp will be replaced by stone structures. The company has a water right and six mill sites on Sinlahekin creek, and at the falls of the creek, a mile distant from the mine, will be placed a turbine wheel, and an electrical plant and pole line will be established for transmitting power to drive drills at the mine. It is planned to begin work this summer with an initial capacity of 1000 h. p. The construction of a mess, bunk and store-house will be one of the first things done. Connection can be made with the Vancouver, Victoria and Eastern branch of the Great Northern system by building a spur from the north end of Palmer lake, nine miles to Loomis and thence eleven miles to the mine.

The Capitol Mining and Milling Co., owning five claims in the Methow district, is sinking a shaft. A crosscut at a depth of 60 ft. shows the vein 37 ft. wide, with ore averaging $14 per ton in gold. A tunnel is being driven to cut the vein at a depth of 200 ft., which it is expected will be finished about June 20. The ore will be concentrated. Work is now being conducted with two shifts.

The Prize Mining Co. is constructing a box chute from the brow of the hill, above the Similkameen river, 2000 ft. in length, to the base of it. Formerly the ore was dragged down the hill. The mill is running and producing rich concentrate.

The Rainbow group of claims on Palmer mountain, one of the oldest in the district, has been re-located by two prospectors, who found galena ore in a shaft at a depth of 35 ft.

Republic, April 27.

(Special Correspondence).—The Napoleon Mining Co. has struck the main vein in their tunnel. They will now increase their shipments materially. For some time past three tons per day have been sent to the smelters from the upper workings. An open fissure, 325 ft. deep, has been encountered. The company is arranging to put in an aerial tramway, to convey ore across Kettle river, and the Washington and Great Northern railway will construct a siding for the company's use.

It is reported that $180,000 has been deposited with the First National Bank of Chicago for an option on the Verde Antique marble quarries on Huckleberry mountain near Valley. The Verde Antique Marble succeeded the United States Marble Co., and owns 400 acres of marble. It has produced marble in great variety of color.

Republic, April 28.

STEVENS COUNTY.

The Dominion Hill Mining Co. has taken over two claims near Addy which it has been operating. The working force will be increased. A shaft is down 100 ft. on the vein, and shipping ore is being stoped on that level. It is planned to sink and stope to a depth of 300 ft. A wagon-road will be built, after which the haulage of ore to the railroad will begin for transportation to the smelters.—At the Easter Sunday trouble between the stockholders of the Waukegan and Washington Mining and Smelting Company, the owners, has been reconciled and work will be resumed immediately. At the Summit, six miles northeast of Orient, N. T. Johnson, of Spokane, Wash., the owner, is starting development.—The Central group is under bond to California people. It is situated on the northerly end of Jumbo mountain, about eight miles east of Orient. This section is recently receiving a good deal of attention from capital.

Orient, April 21.

CANADA.

NORTHWEST TERRITORY.

That the Guggenheims are interesting themselves in far northern British Columbia, is the latest news to follow the advent of Heinze into Kootenay and the Bulkley valley. The Guggenheims have recently acquired the Consolidated Cariboo and are now, it is reported, invading Atlin.

S. H. Plumbe, superintendent of the McKee Creek Hydraulic Co., Atlin, has returned from a trip east, in course of which he visited New York, Ottawa, and other points, and has several interesting things to say about mining in Atlin. The company he represents is making great headway. F. T. Hamshaw, president of the company, who brought down a large nugget the fall before last has purchased the interests formerly held by Mr. Ginaca, which gives entire control of the creek and water-rights to the company.

Mr. Plumbe, while in New York, heard many things that indicate the rapid advance of Atlin in the favor of well known mining men. He heard it stated in various quarters that the Guggenheim company has been taking a lively interest in Atlin and purposes putting in two electric or steam shovels, taking electric power from the British American Mining Company's powerhouse, on two different parts of Pine creek. The steam or the electric shovel works in dry ground. The first steam shovel to go up there was installed by the Northern Mines, Ltd., last season. The advent of the Guggenheim company marks an important stage in the development of the Atlin camps.

Mr. Conrad, of Windy Arm, on the borders of Alaska and the Canadian Yukon, has returned from London where he went to organize capital for more extensive operations on his properties. The mission to London was successful, and Mr. Conrad is now on his way north with an assured prospect of a busy and prosperous season. Windy Arm is reached from Whitehorse, and surveys which will lead to the opening up of the country have already been made. This camp will soon be one of the busiest in the north country.

A letter from L. T. Watson, of Queen Charlotte Island, to a member of the Vancouver World staff, states that Eugene Knapp, the representative of a Seattle syndicate who held an option on Mr. Watson's claims on Graham Island, has closed the deal at $80,000 and has started men to work. At the time of writing, April 4, it was Mr. Knapp's intention to leave Skidegate on April 7 or 8, for Vancouver, to purchase a complete outfit. Mr. Watson says that he has made a new strike on Harriet harbor, from which he expects big results.

YALE DISTRICT.

The total output of the mines of the Kootenay, all districts, for the week ending April 13 was 35,225 tons, and for the year to date 495,300 tons. This was made up as follows:

Boundary—Granby, Emma, Mother Lode, Brooklyn-Stemwinder, Rawhide, Sunset, Strathmore, Rambler, and Preston, the last-named being a new shipper this year, totally 26,012 tons.

Rossland—Centre Star, Le Roi and Le Roi No. 2, 7,724 tons.

Slocan-Kootenay—St. Eugene, 712; Sullivan, 500; La Plata, 37; Eureka, 90; Hunter V., 78; Broadview, 25; Whitewater, 19; Sunshine, 22, and British Empire and Green Horn, new shippers, three tons each, on trial.

The smelter receipts of ore for the week were as follows:

Hall mines, 788; Marysville, 500; B. C. Copper, 4,348; Dominion Copper, 4,697; Trail, 8,463, and Granby, 16,580.

There were no incidents of importance during the past week in the mines. The development of the Centre Star continues to yield good results. This is particularly the case with the tenth and eleventh levels of what was formerly the War Eagle. The task of connecting the Centre Star and War Eagle is in progress, a crosscut being run from the Centre Star to connect it with the War Eagle and connections have been made from the ninth level of the War Eagle and from the sixth level of the Centre Star. The object of this is so that all the hoisting may ultimately be done from the Centre Star shaft, and do away with the hoisting from the War Eagle shaft. The shipments for the week ending this evening were: Centre Star, 4,320 tons; Le Roi, 2,430 tons; Le Roi No. 2, 570 tons; total for the week, 7,320 tons; total for the year to date, 93,385 tons.

Alexander Beyers and a companion ventured into a drift on the 1650 level of the Le Roi mine at Rossland one day last week shortly after a round of holes had been exploded. The gas proved too much for Beyers, and he was overcome and became insensible. His companion, Caesar, picked Beyers up and carried him to the bottom of the winze and then up a ladder way in the winze for 70 feet. Here Caesar became exhausted by his exertion and the effects of the powder gas and came near falling with his burden to the bottom of the winze, which has an angle of 65 degrees. No matter what might happen to himself, Caesar determined to save Beyers, so he took some fuse he had with him and tied the insensible man firmly to the ladder. Then he made his way to the level above and soon had the help of several miners. Beyers was quickly brought to the surface and sent to the hospital. It took several hours to get him in a comparatively comfortable condition.

Notices of Recent Patents.

Dewey, Strong & Co. have offices at 10 Bacon Block, Oakland.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press United States & Foreign Patent Agency, the following are worthy of special mention:

BASEMENT AND LIKE VENTILATOR, No. 818,889 April 24, 1906, P. H. Jackson, San Francisco, Cal.

This invention comprises in a vault and like ventilator, a casing fixed in the covering surface, a cover therefor having exterior openings, a central closed portion with a circular flange extending down from its lower surface, an angular closed bottom to the casing, with a central opening and an upwardly extending surrounding rim, a sleeve turnable and vertically movable upon the rim, and closable against the cover flange, said cover flange being concentric with and adapted to inclose the upper end of the turnable sleeve when said sleeve is in its elevated position, said flange thereby serving to prevent water and dust from passing through the central opening to the basement.

FISHING REEL, No. 818,880. April 24, 1906, Wm. Ernst and Alva A. Patton, San Francisco, Cal.

This invention comprises in a fishing-reel, a frame, a shaft journaled therein, winding-gear and a crank connected with one end of the shaft, gearing fixed to the opposite end of shaft and a coil-spring actuated in unison with said gearing, a casing inclosing the spring and turnable by the shaft, a brake by which the casing may be arrested and the spring independently coiled and a winding-spool turntable upon the shaft and a clutch by which the spool may be connected to turn with the shaft or disengage therefrom.

BROODERS, No. 818,872. April 24, 1906, L. W. Clark, Petaluma, Cal.

This invention comprises in a brooder, the combination of an outer box, heating pipes passing through said box, a frame slidably mounted in the box and through which the said heating pipes pass, said frame having its ends cut away to accommodate the pipes, a removable cover for said frame, and a flexible sagging bottom for the frame, said bottom being in direct contact with the heated atmosphere of the heating-chamber and sagging to permit the backs of the chicks to come in light contact with it.

HORIZONTAL CYLINDER PISTON, No. 818,860. April 24, 1906, F. L. Bates, San Francisco, Cal.

This invention relates to improvements in pistons for engines in which the cylinder is of horizontal type, and is designed to relieve injurious wear and pressure of the piston upon the bottom of the piston. It comprises in a horizontal cylinder, a piston reciprocable therein, said piston-head having the upper and larger portions of its circumference normally with a smaller radius than that of the cylinder and the remaining portion normally upon the same radius as that of the cylinder-bore, snap rings fitting grooves in the piston, and having their separated ends fixed within the space covered by the larger arc of the piston-head.

GOLD SAVING APPARATUS, No. 818,834. April 24, 1906, I. P. Lambing, Denver, Colo.

This invention relates to a device for saving gold in placer, gravel, or hydraulic mining where free gold is to be found. It comprises in a gold saving apparatus, a means for separating gold from associated mineral, said means consisting of a sluice having a bottom composed of a series of rapid inclines and intermediate dams arranged substantially at right angles with the plane of the sluice, with mercury-containing channels at the junction of the lower edges of the inclines and the bases of the dams, and other mercury-containing channels located between the upper edges of the inclines and the faces of the dams and below the upper edges of the dams.

Commercial Paragraphs.

The Nissen stamp mill, handled by Fairbanks, Morse & Co. of Chicago, is being given a trial at the plant of the Boston Consolidated Company, at Bingham, Utah.

The Trenton Iron Co. has issued a new circular illustrating the Bleichert system of rope tramways.

The Smooth-On Mfg. Co., Jersey City, announces that their No. 5 Instruction Book will be sent free on application.

The California Perforating Screen Co. will locate at 367 Harrison St., Oakland, and in about three weeks will undertake to punch metal.

James C. Bennett has resigned as assistant chief engineer of the Selby Smelting & Lead Co., and will take charge of the smelting machinery and equipment department of the Risdon Iron Works. The Risdon announces that they will enter actively into the smelter field.

The Fulton Iron Works of San Francisco announce that their works escaped damage and they contemplate the construction of a new machine shop to handle the increase in business.

R. C. Berkeley has resigned as Pacific Coast representative of the Minneapolis Steel Co. and is now head of the Berkeley Steel Co. with temporary address 1694 Post Street, San Francisco.

Harron, Rickard & McCone are erecting a two-story temporary office building on their warehouse site at 7th and Berry St., San Francisco. They will occupy these new offices about May 10.

The offices of the Brunswick Consolidated Gold Mining Co., the Viloro Syndicate, Ltd., are now on the second floor of the Sturgis warehouse at 2031 Sutter St., San Francisco.

The Robins Conveying Belt Company, Park Row Bdg., New York, have issued an attractive and interesting bulletin on the conveying and handling of excavated earth, rock and concrete materials. This bulletin gives valuable information in a clear way.

The Wellman-Seaver-Morgan Company, of Cleveland, Ohio, has issued a splendidly illustrated and attractive catalog on Electric Hoists.

The control of the Engineering Agency, Incorporated, Chicago, has been purchased by A. G. Frost. In addition to branch in Pittsburg, the Agency contemplates placing representatives in New York and Denver, and the head of the Mining Department of one of the prominent western mining schools will probably have charge of the Agency's western business.

EDITORIAL.

THE MAKERS OF machinery and those who deal in machinery have suffered from the San Francisco fire by reason mainly of the loss of drawings. Most of the firms in the City have their foundries and shops on the outskirts, so that these escaped the conflagration, but all had offices in the business portion of the town and mostly along Market and Mission streets, where the fire raged. With characteristic enterprise, these firms are already at work, making and designing the machinery needed in the mines of the West. They are under the direction of the men who made San Francisco a great mining center, and no temporary disorganization or financial loss has served to stop their business. We make a suggestion to our professional friends and that is, that they return any blue prints or tracings that they have obtained during the last year from San Francisco firms, since these drawings may prove of great service. We limit the age to one year, for it is obvious that our progressive clients have no use for designs that are older than that.

A QUINQUENNIAL CENSUS shows that the population of Baltimore has continued to grow at practically the same rate as before the fire that almost destroyed it. In 1901 the local census made the total 517,035, while the Federal Census of 1900 gave Baltimore 508,957. Through an enumeration carried out by the police, it is found that the population in 1906 is 543,034, showing an increase of either 25,999 or 34,077, according to which of the statistics of five years ago is taken for comparison. Baltimore increased by 74,806 only in the ten years between 1890 and 1900. therefore there has been no falling off. There has been a decline in the ratio of negroes, the new population containing a larger proportion of whites than formerly. These facts offer substantial encouragement to our people here.

WE ARE ABLE to state authoritatively that the erection of the large copper smelter at San Bruno point, particulars of which were given in our issue of April 14, is in no wise affected by the San Francisco conflagration. On the contrary, the work is being pushed with additional energy. The original plans included only one brick building, so that the possibility of another serious earthquake will cause no serious change in the construction. It was intended to erect a brick chimney, 380 feet high, and this detail will be amended; a self-contained anchored steel stack will be substituted. The fact that this large plant will be built without delay is one of much importance to this community, for it will establ the importance of San Francisco as a metallurgical center and an ore market.

THE ADOPTION of a uniform eight-hour day in the mines and smelters of the Amalgamated Copper Company at Butte is an important event. It is a voluntary concession on the part of the great copper corporation and it ought therefore to create good feeling. The step was undoubtedly taken for sound reasons and while the loss to the company is stated at a large sum, it is more than likely that the men will do better work in return for their shorter hours. A man who works honestly for eight hours has done enough and if mine managers have fought the eight-hour movement, it is because they know that the time wasted by employees is such as to make the period of supposed labor much less than the hours indicate. A man who works his seven or seven and a half hours steadily out of the eight hours spent in the mine is more useful as a workman than one who, while underground for ten hours, dawdles or fools away a third of his time. Uniform hours and even short ones are not objectionable even from the employer's standpoint, if he can be assured of uniformly effective work. We welcome the announcement made by the managing director, Mr. John D. Ryan, that the Amalgamated Company will keep out of politics and has buried the animosities of the past. This is good citizenship and sound business.

PEDRO ALVARADO has served as the subject for plenty of inaccurate copy in the daily press. His Palmilla mine is three miles from Parral, in the State of Chihuahua, and it is usually credited with several times its actual production. Alvarado's father owned the mine and worked it in *gambucino* fashion; Pedro himself allowed lessees to come in, and it is they that five or six years ago found the rich ore. This discovery developed into a bonanza, 140 feet wide, so that the mine is making about $50,000 per month. Carloads have yielded $2,500 per ton, but the average is about 100 pesos or $50 per ton. Pedro Alvarado is no *peon* or peasant, but a *baratero* or miner, an important distinction in Mexico. He has built a house that cost a million pesos, and he has done other foolish things that have helped to create tales as to his great wealth. There are 3,000 men in his employ at the mines and these do the work that 1,000 could do, many of them being his old *compadres* and hangers on. Like most stories of the accidental rich, this one loses its romance on closer inspection.

The Need of a Library.

Professional men having offices and homes within the devasted area of San Francisco have suffered great loss by the destruction of their libraries. In extending a comprehending sympathy, we desire also to shake hands with the members of the San Francisco bar who have seen reference books of inestimable value consumed by the flames. And among those lawyers who have often disentangled the complications arising from our curious mining laws, we desire especially to tender sympathy to Mr. Curtis H. Lindley, author of 'Lindley on Mines' whose library was one that has helped many mining men during the years that are past. Men are greater than books, and we trust that the Judge is spared for many years of continued usefulness. The Bar Association of New York has given $5000, as a contribution toward the creation of the new library of the Bar Association of San Francisco. To the disputative profession, the loss of reference libraries is undoubtedly greater than it is to our own profession. To students all books have value, but to the practical engineer and metallurgist, only those that contain the most recent records of technical development are necessary. Technical books more than ten years old have little immediate value and the collections of superseded literature possess mainly a sentimental interest. Therefore the mining engineer's loss is less than the lawyer's, though bad enough.

In relation to this subject, we note that an appeal has been made for help in adding to the usefulness of the mining library started by a gift of money made by Mr. John Hays Hammond. Before the destruction of the City, there had been question whether the State Mining Bureau would or would not give space for these books in its quarters at the Ferry building, and the completion of the plan was hindered for lack of a suitable home. This hindrance is likely to be overcome now, for the need of such a library has been vastly emphasized by recent events. Mr. Hammond gave $5,000 for the purpose and it was arranged that Messrs. Charles G. Yale and Louis Janin

should be trustees, together with the State Mineralogist, ex-officio.

An appeal is being made by the trustees, all of whom are representative men, asking for volumes of scientific and technical papers, and inviting suggestions in regard to the books to be purchased. We think it likely, having regard to the widespread loss caused to the professional men of San Francisco, that several technical and engineering societies such as the American Institute of Mining Engineers, and the sister societies that represent mechanical, electric and chemical engineering will, if practicable, donate a set of their own publications. We also suggest that our friends in London, Melbourne and Johannesburg are good fellows, who, in view of the particular conditions of the case, would be likely to do their best in this regard. The best we can do at this time is to state to those mining engineers, geologists and metallurgists who are willing to help, that the address to which they can forward books is 81 Appraiser's building, San Francisco, in care of Charles G. Yale. This is the most effective help they can offer their professional brethren of San Francisco.

Railroad Building in Alaska.

The mineral development of Alaska awaits the construction of several necessary lines of railway and it appears likely that this means of transport will be largely available in the near future. At present the longest line is the White Pass & Yukon Railroad, from the coast at Skagway to White Horse, where connection is made with a water route to Dawson. This road, famous for the engineering skill with which it was constructed and for the impressive scenery it traverses, is only 110 miles long. There are three short railways on the Seward peninsula: At Nome there is a 12-mile narrow gauge road that runs to Anvil Creek; another narrow gauge, a few miles long, connects Council and Ophir Creek; the Council City & Solomon River Railroad is standard gauge, and 16 miles long. This is an insignificant amount of railroad building for a region so vast, the natural resources of which have been abundantly proved. Of course, the great river system of the Yukon has furnished transport from, and to, the interior, but owing to the shortness of the summer and the difficulties of navigation, this affords but a precarious highway for traffic.

On another page we publish a map indicating the route of the railroads projected for the development of Alaska. Some of these are assured in the near future and all of those indicated will undoubtedly be built within the next five years. Among the railroads first to be built is that which will tap the Copper River district, and proceed thence to Eagle City on the Yukon. The line will be about 500 miles long, starting at Valdez on the coast. From Valdez it is likely to be brought eastward so as to cross the Copper river and follow the water gradient northward to the Yukon. A branch line will go to the copper districts of Bonanza and Elliott creek. It has been suggested that the terminal point should be at Orca, near the salmon canneries, and that a short branch should tap the coalfields on Controller bay. These projects are in the hands of men well able to realize them, so that we anticipate rapid construction. Another railroad is to go from Resurrection bay to Fairbanks, on the Tanana river, serving as an artery to that gold mining district, which yielded $5,107,000 in 1905 and is today the most productive in Alaska. A few miles of track have already been laid from Resurrection bay along the Sushitna river; this line will go up the Sushitna and down the valley of the Cantwell river to the Tanana; eventually it may be extended to the Yukon, at Rampart. The total length will be fully 550 miles. A third railroad will cut across the Alaska peninsula, saving the tedious and often dangerous circum-navigation by way of Unalaska to St. Michael. The road will proceed northwest from Lliamna on Cook Inlet to Anvik, on the Yukon, and not far from its debouchure into Bering Sea. The length of rail to be laid is about 375 miles. Each of these roads will perform specific functions in affording facilities to mining centers already established, but beyond this they will undoubtedly afford new points of departure for exploratory work and in this way they will advance the further development of new regions. The importance of railroad facilities for this purpose warranted the request recently made to Congress for subsidies in aid of construction, but the committee on railroads rejected the bills intended for this purpose, on the sufficient grounds that Federal aid was not needed, there being every reason to believe that ample private capital would be forthcoming. This we believe to be a fact.

But beside land transport, the Territory needs adequate steamship service between the railroad terminals on the coast and the ports to the south, such as Seattle and San Francisco. At present merchandise from San Francisco destined for Nome, St. Michael and the Yukon valley is transshipped at Seattle, but in June a new line of three steamers is to be put on a direct service from San Francisco to the northern ports mentioned. At Seattle, four new steamships are shortly to be utilized to carry freight to Valdez and Nome. Therefore the arrangements for Alaskan traffic are destined to undergo rapid improvement. The development of the region warrants it, for no part of this continent gives better assurance of growing in value as a source of mineral wealth If our people exhibit the enterprise to be expected of them, San Francisco will be the gateway for the receipt of much of this metal output and the distributing point for the machinery and supplies necessary in such productive operations.

When converting pounds sterling into dollars, most of us do it mentally by multiplying with five, which is well enough. But many statistics are seriously vitiated by this careless habit: for a pound is never equal to five dollars. We know of an instance where the price of a mine was ten million dollars United States currency; the promoters in London divided ten by five and remitted two million pounds, only to find out at the last minute that they were $300,000 short—quite a tidy sum, enough to buy a pretty good mine. The error was rectified but not without some scurrying to and fro among casual arithmeticians. While the rate of exchange varies from day to day, in converting statistical data we multiply pounds by 4.85 to arrive at the equivalent dollars. Speaking of such matters, it has become the custom lately to use the term peso in place of the 'Mexican dollar' so as to prevent confusion with the dollar of the United States and Canada. But when we come to the smaller currency we note that 'cents' are still qualified by 'Mexican' or 'American' as the case may be. This occurs in giving the cost of minor articles of commerce or of cheap forms of labor We suggest the use of *centavos* for Mexican small currency and of cents for the American. Thus we shall have the *peso* and the *centavo* in contradistinction to the dollar and the cent. This usage should prove simple and safe.

By the Way.

In 'Popular Science Monthly' Mr. Joseph H. Bair, Professor in the University of Colorado, makes interesting observations on the 'Individual Adaptation to Environment.' He says that as a result of the incorporation into his environment of his cumulating knowledge, man's social and economical conditions are continually changing, but with his increased intelligence he has greater power of adapting himself to the new conditions of life which are inevitably the result. And as soon as man acquired those intellectual and moral qualities which distinguish him from the lower animals, he began to invent weapons, tools and various stratagems to procure food and to defend himself, and was but little liable to bodily modification through natural selection. When he migrated into colder climates he used clothes, built shelter, made fires. He also aided his fellows and anticipated his future. Selection seized upon intelligence and man was enabled to keep an unchanged body in harmony with a changing environment. Progress implies a continued increase of control over nature, through the gradual acquisition of knowledge of her laws.

Education, too, succeeds in maintaining the intellectually unfit by adapting them to the environment intellectually unfit by adapting them to the environment so that they are enabled to make a living and to bring up a family, thus precluding a rise in the average of intelligence in the race. Man is enabled to advance independently of heredity, and natural selection is cheated out of her work. Man can select everything in his world except his own body and mind. He is born with a body and mind which were developed by natural selection and are naturally adapted to the environment that existed when selection ceased. So adaptation to the environment in which he is called upon to live (civilization) must be accomplished through artificial means.

Civilization implies that each generation is working at a higher environing intellectual, moral and spiritual level, and with better tools, which their predecessors from generation to generation have devised and handed down to the subsequent one with usury. The essential thing in progress is that evolution has been transferred from the organism to the environment and that it is the accumulated social structure which persists. Civilization, therefore, is better characterized as a product than as the continual rise of average intellectual capacity. This product is the mold in which mediocrity is cast, and implies, merely, that the level of acquisition is becoming higher rather than the level of intelligence. The mediocre, and even the mentally poor, as well as the apt, are by means of education adapted to their environment and are thus enabled to survive and to bring up a family. Here, too, natural selection is barred from functioning, and for this reason man's mental evolution tends to a limit. One feature, inevitable in education, and which distinguishes social evolution from merely organic evolution, is the predominant part played by the fittest in raising the level of the less fit.

The question comes, can the scholar keep abreast with the times? The most strenuous effort will almost invariably fall short of its attempt. Our ideas integrate into a system. An apperceptional something functions in all intellectual life. The ideas in our minds are the standards by which we receive new truths and ideas. We crystallize into our notions about things; in other words, we form habits of thought as well as of action, and thus become fixed in our theories and attitudes. Considering, therefore, the fact that every subsequent impression upon the mind of a person is viewed in the light of what is already in the mind and fixed, it is not difficult to see why it is almost impossible for that mind to accept an entirely new point of view, no matter how reasonable that point of view may seem to one whose ideas as standards are in consonance with the new view-point.

Often it happens, however, that scholars are far ahead of their times. They are dreamers or prophets. They anticipate a more or less distant future, and their thoughts and standards all integrate into a system consistent with their point of view. There are only a few whom they can interest in their lofty conceptions. The man most popular in his time is he who gives expression to what the world gropes after, who lives what they feel, who makes their felt wants real. But the environment, intellectually as well as physically, is cumulative, and soon society will have outgrown him. He becomes obsolete. He has given them the means of stepping beyond him to a higher interest. They are now shouting to another hero who is helping them still another step higher in realization. The world keeps on shouting, but continually to new individuals.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

When adit levels are run to develop water, drifts should be run on every fissure and seam giving any indication of moisture.

Tinstone and wolframite frequently occur in the same veins, and consequently are found associated in placer deposits resulting from the degradation of such veins.

Acetylene lamps will burn in mines where candles are useless, owing to the presence of carbon dioxide, but it is dangerous for men to venture where a candle will not burn.

Micaceous iron (specularite) is frequently mistaken for galena. The former has a dark red streak, the latter a lead-colored to black streak. Free gold occurs with micaceous iron, and is occasionally associated with galena

That mine is most valuable which pays the largest profit with the least possible capital expense, and which is so situated geologically that when it is exhausted there is no doubt about it, thus offering no incentive to waste accrued profits in hopeless search for more ore.

It is a mistake to construct a mill or build a smelting plant with a capacity far in excess of the mine's ability to keep it supplied with ore. It is the wiser plan to build moderately at first and as the resources of the mine develop, the reduction plant may be extended to meet it.

Modern volcanoes do not erupt acid rocks, but east of Lassen Peak, California, at what is known as the cinder cone, there has occurred a flow of quartz basalt. The rock is fine textured, black and typical dolerite—the fine-grained basalt; but throughout the rock are scattered numerous small blebs of vitreous quartz.

To insure security all pipe-lines on hillsides and not buried beneath the surface, should be anchored to rocks, trees or to posts substantially set in the ground. Air-pipes also should be provided with expansion joints at suitable distances and, if there are any depressions in the line, these must be provided with valves for the escape of condensed water.

The 'caving system' of mining as practiced in the iron mines of Minnesota is not applicable to mines everywhere. In those mines occur peculiar structural and geological conditions which make the caving system particularly applicable, but without suitable conditions the application of this system would not only become extremely dangerous but a financial blunder.

Mine waters are a source of expense in most cases, but there are many instances where the water pumped from a mine may be utilized to good advantage, in treatment of the ore. For the purposes of concentration mine water may always be useful, but in treatment by amalgamation, minerals in solution in the water often interfere seriously, due to the presence of arsenic, chiefly, or sulphuric acid.

At some mines, mispickel is treated successfully by stamping, amalgamation and concentration, followed by straight cyanidation of the tailing, the concentrate being shipped and the tailing cyanided without roasting. In instances where the arsenical ore is too low-grade to admit of shipping at a profit, it would perhaps be the better plan to roast the ore before cyanidation, and then to use bromo-cyanide.

Most new mining districts are discovered by accident. The reason for this probably is that prospectors are inclined to search for conditions with which they have become familiar elsewhere, passing by all other occurrences as of little value. The discovery is often made by one entirely unfamiliar with geology and unprejudiced by previous experience. For this reason valuable mines are sometimes discovered in most unexpected places.

The State of California has few mining laws which add to the requirements of the Federal statutes. The legislature has passed no law which is at present in effect requiring that a certain amount of assessment work be done within 90 days of the date of location, as a part of the act of location; though Arizona and Nevada have laws of this kind. One may safely follow the United States mining laws of California.

Pocket hunters become very expert in tracing 'colors' to their source. They work according to conditions as they find them Some pockets are quickly found while others require long and persistent effort. An expert pocket hunter would naturally be expected to find a pocket from the indications sooner than a novice. It is a business requiring judgment and this only becomes mature with experience.

Owners of prospects often appear to forget that the actual value of their properties may possibly be far below the price fixed by themselves. Owners often hold such exalted ideas of the value of their property or their ores that it is impossible to do business. Claim owners sometimes read the quotations on the retail price of metals and expect to get this price or near it, for their raw product. This is, of course, an impossibility, as the smelters do not, as a rule, receive retail prices.

All kinds of sedimentary rock are known to be goldbearing in various mining districts. In California, gold occurs in limestone in the Black Hawk mountains of San Bernardino county; in sandstone in the Black Hills of South Dakota and in Colorado; in shale in Utah, and in crystallized lime at the Alvord mine in California. The metamorphic sedimentary rocks are also notably goldbearing in many places. Quartzite, slate, mica schist and marble are well known carriers of gold.

It pays at every large mine to have a complete machine shop and in some places the magnitude of operations justifies a foundry as well. In the former, repairs of every description can be made from turning out a new rocker pin for a machine-drill to welding a stem, or turning a shaft in the lathe. Cars, cages and skips also may be built to advantage in the company's shops. In the foundry all of the heavy castings can be made on short notice, and not only money but often much delay saved. Particularly is this the case at mines in an isolated situation, far from railroads.

It is not the number of blows a machine-drill strikes within a given time, altogether, that counts for progress, but also the air pressure back of the drill. In addition to this, the proper manipulation of the machine by the drill runner, is not the least important factor. A chuck-tender of two weeks' experience can scarcely be considered a competent machine miner, yet, not infrequently, such men secure situations with no more experience than that mentioned. Some mine superintendents prefer to break in and train their machine-men, claiming that the general result in the end is far more satisfactory.

The word porphyry means purple, and is the name originally applied to the purple colored rock from which many Egyptian obelisks were made. As applied to rocks, it has only structural significance. As now understood, porphyry is any rock in which distinct crystals of any mineral occur which are larger than the grains or crystals of the ground mass. The ground mass may be very fine in texture or may be quite coarse. A fine-grained, dark-colored rock in which occur white crystals of feldspar is porphyry; a fairly coarse granite in which occur crystals of feldspar an inch or two in length is also porphyry. There is also quartz-porphyry, hornblende-porphyry, feldspar-porphyry, etc. Porphyrite is a name applied to basic rocks having a porphyritic structure, as diabase-porphyrite, or diorite-porphyrite and others.

It is generally conceded by authorities that the existence of open spaces is necessary for the formation of ore deposits of any kind. These open spaces may be extremely minute, interstitial openings in a fractured, crushed rock mass, or they may be of considerable size in a coarse breccia. The ore may have been deposited in these open spaces between the pieces of the fractured rock mass or in the small cavities between the grains of porous rock, as sandstone. Some ore deposits undoubtedly have been formed by replacement—that is, as the mineral-bearing solutions passed through the rock, atoms of the rock mass were dissolved and carried away in solution, being replaced by atoms of the sulphide minerals now constituting the ore deposit. Bodies of lead, iron and zinc sulphide in limestone are typical of this method of formation, while deposits in sandstone are well illustrated in many California quicksilver mines. There is nothing to support the belief that the spaces now occupied by large ore deposits were at one time open caverns.

There are no means by which the 'drift' of a diamond-drill hole may be anticipated, though instruments have been devised by means of which their departure from a true course may be measured after the hole has been bored, or during the progress of the operation. One hole bored through given strata may drift to one side 100 ft. or more in 1000, when another hole in the vicinity passing through practically the same strata may have a very small departure from the original alignment. Holes started horizontally always drift upward, due to the fact that the cutting bit is slightly larger than the pipe line connecting it with the drilling machine, the pipe sagging a little in the bore-hole, causing the bit to work upward slowly.

Although a Colorado district court recently decided that locators of mining claims who have failed to do the annual assessment work prescribed by law in order to hold title to the same, have the right to re-locate the same as any other party who may jump the claims after the first location becomes void by reason of failure to perform the necessary work, holding that re-location would hold good at law, providing it was made before the location by the other parties after the first location had become void. It is doubtful if the United States Supreme Court would sustain this decision on an appeal. Such a ruling would have the effect of subverting the intent and purpose of the law, and the claimholder who fails to perform his annual assessment as required by law, would simply profit by his own negligence and hold his claim indefinitely without any development. Re-location once each two years would suffice to hold the claim indefinitely.

The law of Montana (Comp. St. 1887, div. 5, ss. 492-294), providing that the officers of a mining corporation shall have no power "to sell or otherwise dispose of" the whole or part of its mining grounds, mills, and plant, without such transfer being first approved by the holders of two-thirds of the stock, at a meeting at which at least three-fourths of the stock is represented, and that, if such sale be of the entire corporate property, the corporation shall be dissolved, is merely a limitation of the common law powers of directors and majority stockholders of a corporation, and does not authorize two-thirds of the stockholders of a prosperous company to sell all of its property against the protest of the other stockholders, or any of them. A transfer of all the property of a corporation to a foreign corporation organized by the directors of the former to acquire its property, in consideration of the latter assuming its liabilities, and agreeing to deliver to it its entire stock, stockholders of the former to exchange their stock for shares in the new company, or in lieu thereof to receive a fixed sum per share for surrendering them, is neither a sale nor an exchange within said provisions, conceding a sale or exchange to be authorized by such law. This is the gist of a decision of the Montana Supreme Court in the case of Forrester vs. B. & M. Consol. C. & S. Min. Co.

Disputed Location. The case of A, B and C, contending for mine locations in Arizona, is somewhat complicated, but in our opinion the title still rests in A (the company). The question of abandonment is largely one of intention, and it does not appear from the statement of the case, made by B, that there was any intention on the part of A to abandon the property. B, as a stockholder, had a personal interest in the mine, and was in the employ of the company owning them. He did a portion of the annual assessment work, and was engaged in the completion of this work on the last day of 1905, and was still so employed on the first day of January, 1906, with the knowledge and consent, if not at the direction of A. The fact that A had no ready money with which to pay B for his labor would not affect A's title to the ground, and was merely a personal matter between B and the company, A. As A was showing good faith, in so far as the government is concerned, B had no legal right to re-locate the ground either for himself or another, and C had absolutely no business on the premises whatever, being a trespasser. As A owes B $500 for labor performed, it B cannot collect the money due him from the company, A, he may bring suit and attach the property, under labor lien law, but he cannot convert the claims to his own use by the act of location.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A CRITICISM AND A SUGGESTION.

THE EDITOR:

Sir—It seems to me that one of the reasons for a certain amount of the enmity toward science as represented by geologists and existing among the ignorant as represented by machine-drill runners like myself, aside from the frequent inability of eminent geologists to agree on important specific problems, is due fundamentally to the Huttonian method of reasoning. That is reasoning from the near to the remote.

The crime that I mean to impute is the general haziness and lack of proportion in which the whole subject of geology is enveloped, from the original formation of the earth's crust down to present ore deposits. To make my meaning clear, I will give a few quotations from 'A Treatise on Metamorphism,' by C. R. Van Hise, and criticise them from my point of view without intending to attack Mr. Van Hise particularly, but rather to show how geologists lay themselves open to criticism.

In speaking of the source of the material constituting limestone, Mr. Van Hise says: "The original dominant source of the calcium magnesium carbonates is mainly the many alkaline earth-bearing silicates." Now that is all very well, but when you question the source of the many alkaline earth-bearing silicates and reason on the same lines you can only come to the conclusion that the original crust of the earth is a slag or magma of a definite composition, calculated by Mr. Clarke to be composed of oxygen, 47.29 per cent; silicon, 27.21 per cent; aluminum, 7.81 per cent; iron, 5.46 per cent; down to the smaller percentages of other elements.

Further on Mr. Van Hise says: "The source of the water of the hydrosphere is uncertain. If any considerable proportion of the water of the hydrosphere was produced by the oxidation of hydrogen during the time the sedimentary rocks were deposited, the amount of oxygen thus consumed would have been enormously greater than the amount of oxygen now in the atmosphere." Then follow some pages showing the possibility of water being formed from the hydrogen which occurs occluded in various rocks and through action of solfataric springs, etc. In regard to oxygen he says: "It appears that the chief certain source of oxygen of the atmosphere is the reduction of carbon dioxide by vegetation and a burial of a part of this vegetation in the earth. This source is vast in amount." Now, why is it not more simple and more reasonable to suppose that the water of the hydrosphere was formed from the original gaseous sphere before there was any crust to the earth at all?

Let us skip a few hundred pages of matter that does not especially concern the miner, and take up the subject of ore deposits. In California I have found that if you ask a mine manager or superintendent where the ore came from to form any particular deposit, the chances are that, with a wave of the hand, he will state that it came from below. In Missouri, however, a different state of affairs exists. The mine manager says very distinctly, "We don't give a damn where the ore came from." Nevertheless, there is a certain amount of interest in the source of the metal of any ore deposit. Martin Schwerin, for example, in your issue of March 31, wants to know in several specific instances where the ore came from—whether above, below, or from the walls.

In this connection Mr. Van Hise states: "I have little doubt that the metallic constituents of ores are in large part derived from the igneous rocks which have been intruded into or extruded upon the lithosphere." Further on, after considering various iron, lead and zinc deposits, he says: "While it is held that the metals for numerous and important ore deposits do not have their immediate source in igneous rocks, it is recognized, as stated at the outset, that ultimately the metals for all ore deposits are probably to be traced back to igneous rocks." It appears to me personally that it might just as well be stated that the ultimate source of the metals is the original sphere of gas from which the earth was consolidated as far as any assistance is afforded to a man trying to extract at a profit the ore from any particular deposit. What is of more importance in Mr. Schwerin's case is this statement: "In the case of a given ore deposit, by wise combination of the criteria given, it is generally possible to make a somewhat reliable judgment as to whether or not the ore was produced solely by ascending waters. Criteria meaning many pages on circulation of underground waters, solubility of metals in various aqueous solutions, etc.

Now, if you will kindly give me the space, I will offer, subject to criticism, my own particular notions on the subject of ore deposits: Start with a spherical body consisting of equal parts by volume, in the gaseous condition, of all the known and unknown elements. As this spherical body began to cool, the gases began to condense, combine and precipitate according to a definite law. Those elements which combine most readily with oxygen precipitating first and in the same way that in chemical mixtures the compounds crystallize in such order, and the separated solid is of such character that the freezing point of the remaining liquid is lowered, and after one compound has separated another follows, which again lowers the freezing point, and the liquid left is the last compound to crystallize. Thus hydrogen combined with oxygen to form steam, and, later, water. Silicon formed particles of silica. Aluminum formed alumina; iron, magnesium, zinc and other elements followed in their regular order, until a crust was formed on the sphere of such a thickness as to interfere with the process. Smelting processes then began to take place locally owing to the continual contraction of the sphere and other causes; that is, sections of the crust plunged in just as cakes of ice are sometimes seen floating on edge or partly forced under. The smelting processes were not always complete. They were similar to the effect produced when fluxes are added to an assay-charge already melted or to a crucible of melted gold, and there is not enough heat from above to form a slag of new composition. This produced a great variety of igneous rocks and also introduced a certain amount of the heavier, less easily oxidized, non-oxidizable and more precious metals in the shape of prills from below into the range of the converter processes. The converter processes were due to the same causes and were going on locally at the same time as the smelting processes. To illustrate this idea, ignite two hundred pounds of fine zinc shavings on a breezy day and note the disseminating effect, or hang around a copper smelting plant and watch them over blow one or two converter charges, also notice the flue-dust and fumes. The smelter and converter processes continued during the formation of the so-called sedimentary rocks and the resulting fumes of the more readily oxidized metals, and metallic particles of the less readily oxidized and non-oxidizable metals were locally deposited in them and disseminated through them.

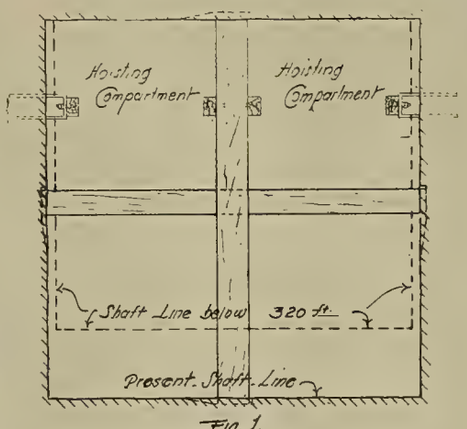

Fig. 1.

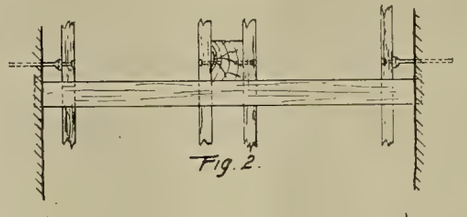

Fig. 2.

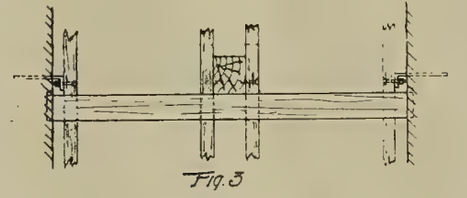

Fig. 3

That is to say: All primary ore deposits are the result of either the mechanical concentration of metallic particles and of relatively insoluble metallic oxides resulting from the erosion and decomposition of sedimentary rocks or else the result of the leaching of metallic particles, oxides, and salts through aqueous solutions, from the sedimentary rocks. The influence of intrusive bodies of igneous rock on currents of aqueous solutions of metals, through heat, and their action as barriers or as basements, has been brought out very well in the discussion following Franz Posepny's treatise on ore deposits, though there is still some cloudiness as to the nature of those aqueous solutions.

RICHARD C. HARRISON.

Tangier, Nova Scotia, April 18, 1906.

THE BEST SHAPE FOR A SHAFT.

THE EDITOR:

Sir—Another plan might well be employed in connection with the 10 by 10 ft. shaft, whereby the side buntons are done away with and brackets employed as a support for the guides, since the rock surrounding the shaft described by Mr. Burrows is so strong and coherent as to permit the use of such brackets. Let the center bunton be enlarged to such size that stiffness under the swing of the heavily loaded skip is assured, by the use of 10 by 12-in. timbers placed edgewise with the shaft; a single cross-bunton of smaller cross-section being used to separate the hoisting from the auxiliary compartments. To this main center bunton the interior guides are hung in the usual way by lag-screws. See Fig. 1, 2 and 3. At the sides of the shaft the guides are hung to brackets, single or double shanked, which are attached to the wall of the working by holes drilled at proper points, the shanks of the brackets being introduced into such holes and being permanently fixed therein by running in melted lead to fill up the interstices between the sides of the holes and the iron or even, possibly, by the use of cement. It is probable that the single-shanked bracket would be sufficient for all purposes and it would be more easily made and placed than would the double-shanked one. The face against which the guide would bear should be made perfectly flat and of a width equal to that of the guides. To such brackets the guides could be attached by means of stock bolts, double or lock-nuts being employed to prevent any possibility of their becoming loosened as with lag-screws.

A clearance of four inches would be ample where such brackets are used, and therefore with a center bunton of a width of 10 in. and a width of each hoisting compartment of four feet the shaft below its present depth could be narrowed three inches at each side, to a width in the clear of 9 ft. 6 in. With a width in the other direction across the hoisting compartments of 4 ft. 6 in., a center bunton eight inches wide, and with the subsidiary compartments narrowed in the same direction to a width of three feet, the width of the shaft in this direction would be 8 ft. 2 in. The cross-section of this 9 ft. 6 in. by 8 ft. 2 in. shaft would be 76.6 sq. ft. as against 80 sq. ft. for the 5 by 16 ft. shaft projected. Besides requiring the breaking of less rock in this construction a further economy would result in thus doing away with the necessity of making clearance for the side buntons in order that they may be brought to position and exactly aligned; with the use only of the center buntons, the squaring up of the shaft would be a less exact and therefore a more simple and rapid process than when even slight irregularities of the wall-rocks must be removed to accommodate the placing of side buntons.

The advantages of this construction, under the conditions advanced by Mr. Burrows, may be summed up as follows:

1. The shaft can be cut more readily to the required dimensions than can the single-width shaft.
2. It can be made even narrower than the assumed 10 ft., whereby a less quantity of material will be extracted than in the 5 by 16 ft. shaft.
3. A minimum of timber would be required to equip the shaft as thus constructed.
4. The brackets could be more cheaply and quickly placed than could the side buntons, and unless the iron should be subjected to the action of acid mine waters the brackets would be far stronger and more permanent than would the buntons.
5. By means of guide-bolts fastened with lock-nuts in place of the lag-screws the guides would be more securely and permanently held in place than could otherwise be accomplished.
6. Such a construction would be more economical in every way than would the application of side buntons or regular framed sets to the shaft.
7. Finally, the character of the rocks enclosing the shaft, as has been proven by other shafts at Guanajuato, is such as will permit the use of wall-brackets to the best advantages and therefore the above plan is entirely feasible.

WILBUR E. SANDERS.

Helena, Montana, May 2, 1906.

Hydraulic Mining by Pumping.

Written for the MINING AND SCIENTIFIC PRESS by DENNIS H. STOVALL.

Until one year ago hydraulic mining by pumping or forced power was something of an experiment. It had been tried in various mining districts without much success, the main reasons being lack of cheap natural power, inadequate pumping equipment, and deficient working ground.

It remained for the Golden Drift Mining Company, operating in the Dry Diggings district of southern

HYDRAULICKING ON ROGUE RIVER, OREGON.

Oregon, to successfully solve the problem of hydraulic mining by pumping. This company has amply demonstrated that where proper facilities exist, placer mining can be done by forced power, thus overcoming the embarrassment of long seasons of idleness through the summer months, of light rains and slack water supply for ditches and reservois.

In the property of the Golden Drift Mining Company are included 800 acres of ground locally called 'dry diggings,' because the very best seasons afford but 60 or 90 days' run for the giants. Rogue river, a wild, turbulent stream, at no time flowing less than half a million miner's inches of water, flows along the eastern border of this tract. M. C. Ament, the manager, believed that the Rogue river could be harnessed, and its power utilized for hydraulic mining. He was supported in this belief by his father, C. G. Ament, and other officials of the company. Liberal financial backing was given, and the dam was begun. It was a tremendous task, and two years were required to complete it. Over 4,000,000 ft. of lumber were used, and over 3,000,000 tons of rock were filled into the monster cribs, which were first pinned to the bedrock by 40-ft. piling. The dam has a length on the crest of 265 ft.; it is 120 ft. thick on the bed of the river, and is eight feet wide on deck. It has an 80-ft. abutment, 80 ft. wide. The penstock is 120 ft. wide, and has twelve 10-ft. gates by which the water is admitted to the turbines. During the year the plant has been operated, the tailing from the fumes has been dumped into the river above the dam, and this has made a solid rock-filling, which has practically raised the bed of the river up to the level of the deck, a level that is maintained for a quarter mile up-stream.

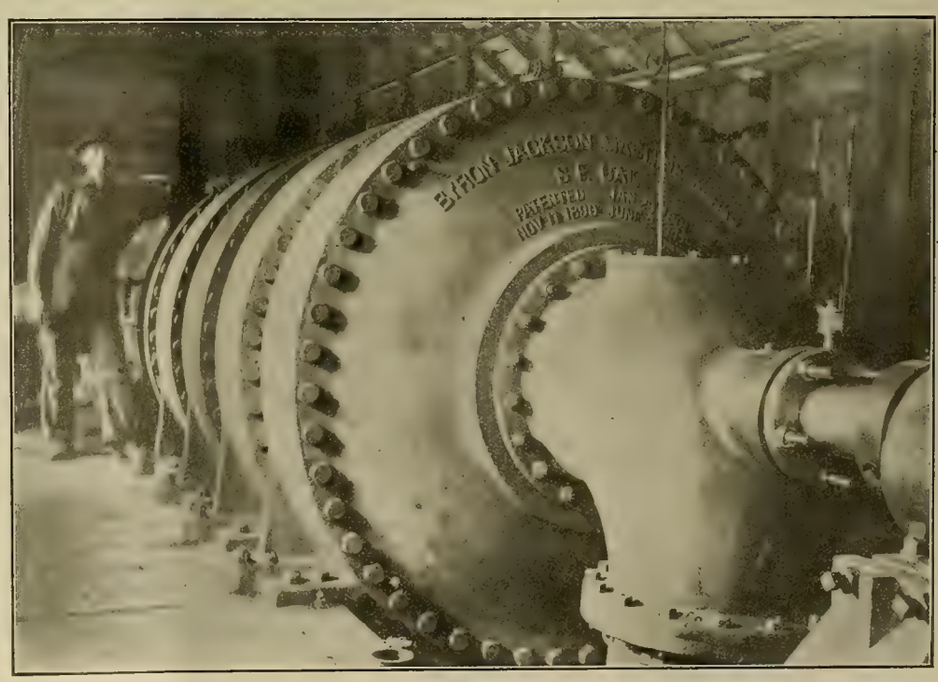
The fall of water over the crest of the dam is 20 ft., and this develops 6,000 h. p. At present, four turbines are operated, developing 1,200 h. p., all of which is delivered to the one pump. Two additional turbines are being installed, the power of which will also be delivered to the one pump, that it may operate to its full capacity. This summer ten additional wheels will be installed, and two more pumps added, by which three giants can be operated instead of two, besides affording abundant bank or by-water.

The pump, which is the heart of the plant, is of the five-step centrifugal type. It was built by the Byron Jackson Machine Works, of San Francisco, and is said to be the biggest high-head pump in the world. Its weight is 35 tons, and its tested maximum pressure is 250 lb.; the operating pressure being 185 lb. per sq. in. Its capacity is 13,000,000 gal. per 24 hr., or 9,000 gal. per min. This great volume is delivered through 1,500 feet of 22-in. steel piping, and is lifted to a height of 170 ft. before dropping into the diggings, and forking to the 11-in. giant pipes.

The highest pressure attainable with the 1,200 h. p. now developed is 145 lb. per sq. in., or 40 lb. less than the pump's normal capacity. Mr. Ament believes that the addition of the two turbines now being placed will raise the pump to its full efficiency, and give greater cutting power to the giants. The monitors have three-inch nozzles, and throw a stream 460 ft. Mining is done, however, from a distance of 100 or 150 ft. The banks are from 40 to 65 ft. high, and are easily cut by the jets. The gravel lies in strata of brown and blue, with red clay capping. The coarse gold and nuggets are found in the lower layers. The finer or average gold occurs in the pipe clays occupying the layers in the center of the banks, and the flour gold is found in the clay capping.

The system by which the pumping battery is operated is simple, the main purpose being to keep the giants always pointed to the gravel. Night and day they are operated, with only a 20-min. stop each evening to oil up. Two systems of sluices are employed, with block and strap iron riffles; while one riffle system is in use, the other is being cleaned up, thus obviating the necessity for a complete shut-down. When the big pump is closed down each evening, it releases the herculean force from behind 26,000 gal. of water, the volume required to fill the long pipe-line. To prevent the 170-ft. head from hurling this great weight of water back upon the pump, a check-valve is placed at the base of the pipe-line; and the work of starting the pump against this great volume of water is made simple by first releasing the water through a side-pipe into the race, and slowly closing it, thus switching the pump to the main line by degrees, until it attains its normal working pressure. Both the speed and the pressure of the pump are registered by gauge in the power-house.

Welding.—In the days of wrought iron, welding was the basis of all forging and of very much structural work. Today almost all structural members are made of steel, as well as a great proportion of the stock that is in the shop of the village blacksmith. This soft steel will weld and the average blacksmith and machinist, to say nothing of some engineers, who ought to know better, believe that a welded piece of steel is as good or practically as good as a new bar. While such a weld is better than nothing, and while it may have half the strength of the natural bar, and may have the full strength, it does not have the toughness, and is unfit for use in any place where failure will be dangerous, and where it can possibly be avoided. A weld of wrought iron is entirely unreliable. This is the case even where the welds are carefully made by smiths of long experience in handling steel, and with bars easily heated and quickly handled.



FIVE-STEP CENTRIFUGAL PUMP EMPLOYED BY GOLDEN DRIFT MINING CO., OREGON.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The blue rock marked J. E. R., Columbus, is a dumortierite. It has no particular value, except possibly, as cabinet specimens.

The rocks from Manhattan, Nev., are: No. 1, hydro-mica schist; No. 2, also hydro-mica schist, but finer textured; No. 3 is a silicified country rock and contains visible gold.

The small white pebbles from Columbia, Arizona, are chalcedony (quartz) and are probably amygdaloidal, having formed by infiltration of silica into air vesicles in a lava.

The gray sand from the drift mine near San Andreas, Cal., should be sent for investigation to the United States Geological Survey, in care of Dr. David T. Day, at Washington, D. C.

The rocks from Lyons Peak, San Diego county, Cal., are Norite. This is a basic rock approaching diabase in the occurrence of the minerals, among which are brown hornblende, labradorite, olivine, and oligoclase. The rock contains no quartz.

The mineral sample from Everett, Wash., marked A. W. M. is quartz, in which is disseminated pyrite. It should be assayed for both gold and silver. The presence of these metals, unless they can be seen, is not in our province to determine.

The rocks from Cerbat, Arizona, have been classified as follows: No. 1, Granite, in which is developed a semi-gneissoid structure. The minerals present are quartz, orthoclase, hornblende and muscovite; No. 2, Quartzite, containing a little copper-iron sulphide; No. 3, semi-crystalline limestone; No. 4, consists almost wholly of hornblende, though biotite, quartz and a little feldspar are also present. It may properly be called Quartz-Mica-Diorite; No. 5 is kaolinized feldspathic dike rock; No. 6, a basic dike rock, too much altered by infiltration of foreign minerals and subsequent oxidation to make determination possible; No. 7, Aplite, fine-grained micaless granite.

Sample No. 1 from Placerville, Idaho, marked A. C. G., is feldspar-porphyry. It is much altered. No. 2 is an altered eruptive rock, probably a greenstone, containing much pyrite. No. 3 is similar to No. 2, but contains more pyrite. No. 4 is evidently a portion of the same rock as No. 2, though containing more silica (quartz) and more iron sulphide (pyrite) than any of the others. Nos. 2, 3 and 4 should be assayed for precious metals, particularly No. 4.

Vein Mining in Alaska.

Written for the MINING AND SCIENTIFIC PRESS by CHESTER W. PURINGTON.

From a territory comprised within two square miles on Douglas Island, Alaska, a sum in excess of eight millions of dollars has been won in dividends from the mining of gold quartz. Although Alaska is an area of nearly 600,000 square miles, or four times the size of California, no other portion of its immense area has yet afforded a vein mine producing metal which has paid any dividends, as far as known. Considering the time which has elapsed since 1885, when the Treadwell group began producing heavily, the fact just noted is remarkable.

Alaska should be considered in three separate provinces: 1. The South Coast province, including the strip of land extending north and west from the southern boundary to Mount St. Elias, the Alexander Archipelago, and farther to the west, the land to the south of the St. Elias, Chugach, and Alaska ranges, the Kenai, and Alaska peninsulas, Kodiak island the Shumagins, and the Aleutian islands. This is the most important province from the standpoint of metalliferous veins. 2. The Bering Sea province, comprising the coastal region to the north of Alaska peninsula, bordering on Bristol bay, and Norton sound, and the Nome or Seward Peninsula region. 3. The Interior province includes all the country to the north of the St. Elias and Alaska ranges, the drainage of the Tanana, Yukon, Kuskokwim, and Koyukuk rivers, to the Arctic coast.

1. In the Alexander Archipelago portion of this province, conditions for quartz mining are fairly good, as for example transportation facilities, labor, water, abundance of timber, and the fact that there are no important producing mines on Prince of Wales, Kupreanof, Admiralty, Chichagof, and Baranof islands or on the adjacent Alaskan mainland, leads one to believe one of two things, either that the country has not been sufficiently prospected, or that those veins which have been opened up have proved too poor to work. As a matter of fact there has been a considerable amount of prospecting. The region directly about Juneau, in Silver Bow and Sheep Creek basins has produced some gold and silver from belts of stringers in the schistose rocks which there prevail. The operations are small, however, and I have never seen a published statement of the results. There have been some costly mining experiments on Baranof island. In Lat. 55° north, near the British Columbia border, there has been active prospecting on the islands and mainland since 1897. Veins carrying gold with large relative proportion of copper have been uncovered, but the product either of gold or copper has been unimportant hitherto. It must be admitted that there are large areas unprospected in the Alexander archipelago, as the whole region is covered with a formidable vegetable mat, rendering access to the interior of the islands nearly impossible, while outcrops are exposed only on the shores and in creek beds.

In the Lake Atlin district of British Columbia, prospecting has been in progress on Windy Arm, and extravagant reports have come out of bodies of high-grade silver ore enccuntered on the surface. It matters little whether these reports are correct or not, so far as Alaska is concerned, as the veins are not likely to have their extension in American territory.

In the most westerly portion of the South Coast province there are undoubtedly bodies of copper ore of considerable size in the vicinity of Mt. Wrangel (Lat. 62° north), and in the Copper River drainage. Every year come the same marvelous reports, the same squabbles over locations, yet no machinery goes into the famous copper districts, and no copper comes out except in the form of specimens. One does not hear even that the claims have been patented. In some of the islands of Prince William sound, deposits of chalcopyrite are being prospected, and some shipments are being made. It is probably safe to estimate that 100,000 lb. copper per month are being produced, the bulk of the ore being smelted at Tacoma. Here again the islands are not thoroughly prospected, and it is not impossible that important orebodies may yet be uncovered.

On the Kenai peninsula prospecting has resulted in the finding of small quartz veins, which occasionally exhibit free gold. The veins are mostly narrow, and I do not remember to have seen any exceeding eighteen inches in width.

Coming to the western portion of the South Coast province, the region to the west and southwest of Cook Inlet is fairly promising. The geological conditions in the region intersected by the Yentna river and its tributaries are such that one may reasonably look for workable gold veins. There are said to be promising copper leads at the head of the Sushitna river.

The volcanic range forming much of the Alaska peninsula, the Shumagin islands, and the Aleutians may contain payable gold deposits. It is on record that the Apollo mine on Unga island has produced over $700,000 and a statement of its financial results would be interesting, but as far as I know none has been published. The deposit is a reticulated vein in a country of fresh dacite. It is situated in a region of extremely recent volcanic rocks, and it is not unlikely that the Apollo represents the most recently formed gold deposit known. Very little prospecting for similar deposits has been prosecuted among the Aleutians and on the adjacent Alaska mainland. It would not be surprising if workable orebodies of limited size, occur.

2. There is one quartz mine producing gold in the Solomon River district of the Seward peninsula. The enterprise is small, but I believe financially successful. The publication of data concerning its production and the cost of that production would be extremely useful, as it is the sole representative of quartz-mining industry in an isolated section. There is much prospecting for gold-bearing quartz in the Seward peninsula, which may eventually result in the establishment of productive mines.

The tin-bearing veins of Cape York afford some promise of future production. Up to the present, the industry is entirely in the prospective stage. Conditions for mining are extremely difficult at Cape York.

As for the rest of the Bering Sea province, including the whole coast-line south from Norton bay to Bristol bay, there are no data for forming an opinion of its mining possibilities. A large portion of the area consists of tundra-covered flats in which outcrops do not occur; the chances are that it will always remain a great non-productive waste.

3. In the Interior province of Alaska there is no quartz mine which is producing gold, silver, copper or any other metal. Reports of copper deposits at the head of the Tanana and White rivers continue to be circulated. However rich they may be, they are without value in the present stage of Alaska development.

The placer mining districts of Fairbanks, Birch Creek, Forty-mile, as well as the Klondike district of the Yukon Territory, derive their gold from stringers in the slate and schist, and the development of any profitable mines seems not even a possibility in those districts. In the course of a trip of 250 miles from Circle to Fairbanks, where good opportunity was afforded for seeing the rocks, I observed only one quartz vein exceeding six inches in width. I believe that when the tributaries of the Kuskokwim, which head in the McKinley range, have been more thoroughly explored, gold-quartz veins of considerable value will be found.

That part of Interior Alaska which lies to the north of the Yukon river may be practically eliminated from consideration so far as the future of vein mining is concerned, as no deposit except one of extraordinary richness could be worked under the extremely rigorous climatic conditions which obtain there.

Core Drilling.—One of the ways in which diamond core drills are now being extensively used, is in testing foundations for tall buildings, dams and other structures which have to be erected on solid rock in order that their foundations may withstand enormous weights and strains. The American Diamond Rock Drill Company is now engaged on a contract to determine the nature of the foundation rock for the proposed new dam in the Croton watershed, in New York. The core drill being used for this work is adapted to drilling from 650 to 800 ft., but on a recent test it succeeded in attaining a depth of over 1000 ft. The ground was exceedingly rough, and the holes had to be drilled in a steep side hill and through materials varying from sand to heavy boulders and rock of every degree of hardness, making the work exceedingly difficult to perform. The drill was a No. 8 Marline, mounted in Style B, with boilers and pumps complete. It is designed to take out a 1¼in. core and will bore at any angle. It weighs 675 lb. set up and required eight horse-power to operate it.

In forging rock-drill bits those for medium hard rock should have sharp chisel bits. As the hardness of the rock increases, the angle of the bit may be made more blunt, and the cutting edge shaped from a straight line to a curve, to prevent the corners being chipped off.

The United States Steel Corporation will carry on explorations for iron ore in the Adirondacks this summer.

Methods of Hand-Drilling.

Written for the MINING AND SCIENTIFIC PRESS by W. R. HULBERT.

It often happens in prospecting that considerable rock has to be excavated in order to determine the value of a mining property; and, as a general rule, prospectors have to work out of the range of mechanical conveniences. It therefore becomes necessary to choose some method of drilling which will be effective and fast but at the same time free from cumbersome machinery. Aside from this, however, there are numerous other cases where the amount of rock to be excavated is so small that it would not warrant the expense of installing boilers, air compressors or dynamos for the operation of the various systems of power-drilling which are now on the market. The question then arises as to which method of hand-drilling shall be adopted; that being the only system which requires no auxiliary apparatus.

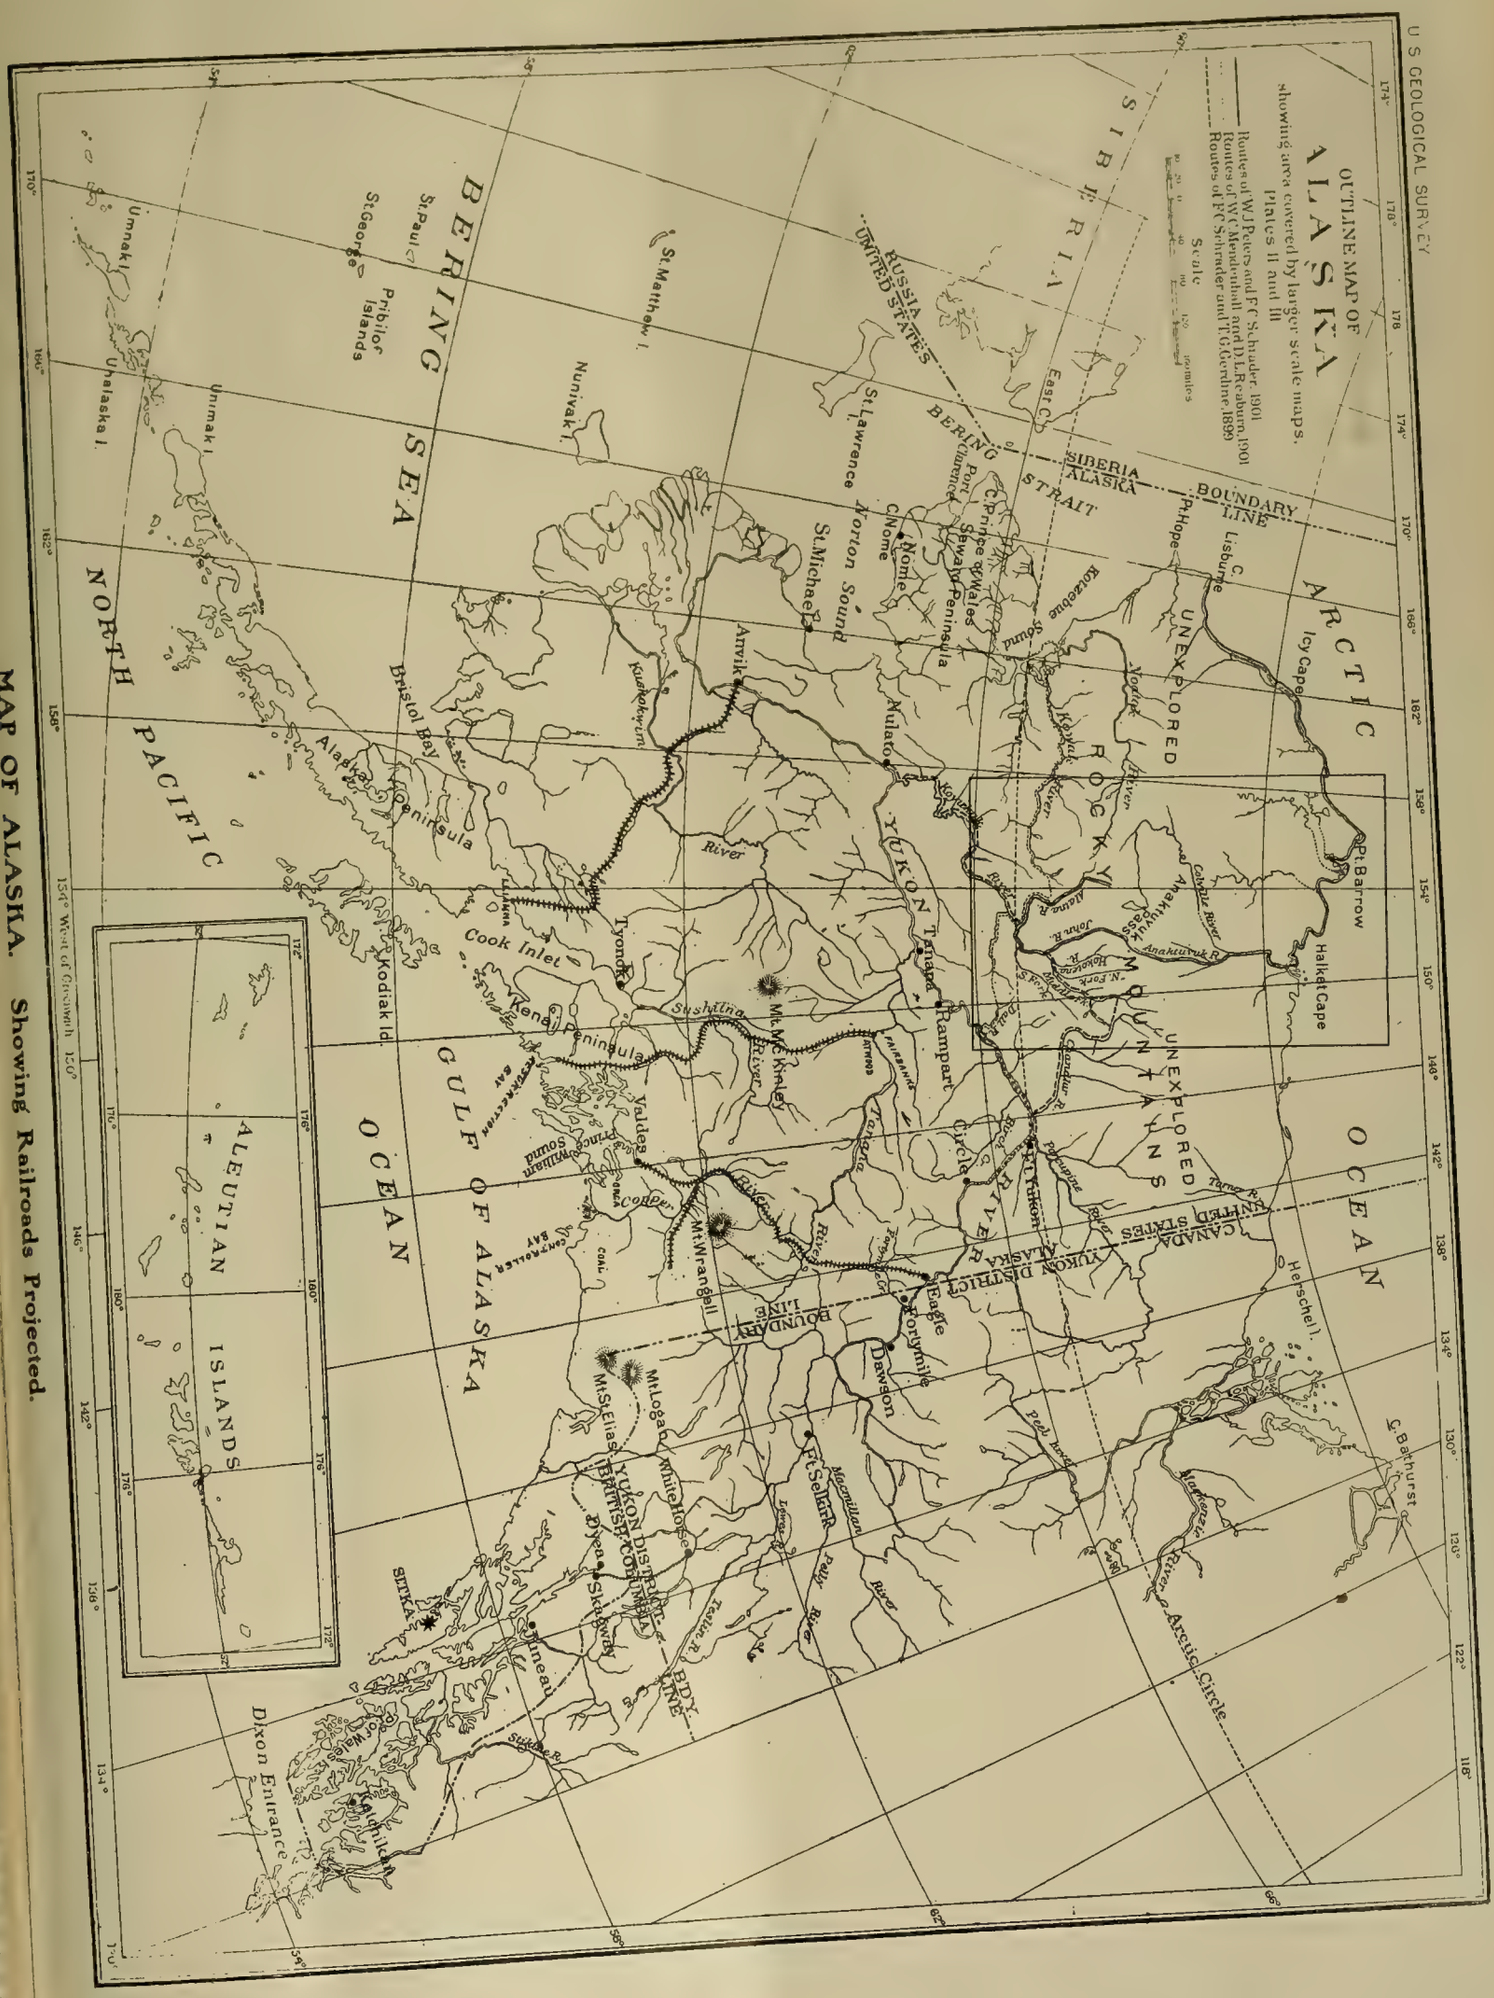
It is not the intention of this article to go into the cost of rock excavation by the different systems of hand-drilling, that subject having been thoroughly treated by the different works on rock excavation by Gillette, Prelini, etc. It is rather my object to discuss the various systems impartially in order that the reader may gain an idea of their relative merits. This is really the only fair way to discuss the subject, since the muscular force of men and animals varies with race, species, size, health, training, temperament and muscular endowment of the individual.

Another factor of importance which must be considered in this connection is that large powers can only be obtained by the aggregation of many units, and a limit is set by the endurance of the individual. In order therefore that a maximum effect may be obtained, it is necessary to devise or adopt a system of drilling which will permit of a uniform expenditure of effort throughout the working day.

There are three systems of hand-drilling now in general use; the first, of course, being the old-fashioned hammer and bit method which is still the system most frequently seen and which is probably the best for drilling short holes and for plug and feather work, since it can be used successfully by any class of labor, no matter how ignorant. Furthermore the tools are simple, easily procured and easily transported. With this system it has been found to be more economical to let one man do all the drilling, instead of having one man hold the bit while one, or perhaps two or three others, do the striking with sledge hammers. Two other methods of hand-drilling have been devised, the first of which is known as the 'churn' and is similar in every way to the systems now being used for drilling artesian wells, a heavy bit being raised by hand and allowed to fall, thus cutting its way through the rock. This system has certain advantages, in that the force of the blow is not absorbed in the bit, but it also has grave disadvantages due to the fact that it is practically limited to the drilling of vertical holes and requires skill. Another objection is the trouble experienced in starting holes with this kind of an apparatus. It will be seen therefore that churn-drilling does not solve the problem entirely, and a great deal of time and thought has been expended in order that a hand-operated drilling machine might be produced that would work equally well for either short or deep holes, and that would operate either vertically or horizontally.

It is a well recognized fact that a man can do a great deal more work by turning a crank than by operating a hammer. Rankine gives the daily work developed by a man hammering as 480,000 foot pounds, and in turning a crank 1,296,000 foot pounds, being in the ratio of 1 to 2.7; and while the conditions of the work with the revolving crank are probably less favorable than with a winch under practically steady load, (the case considered by Rankine), the fact remains that the turning of a crank, with resistances fairly balanced by a fly-wheel, is a better way of utilizing a man's strength than by the consecutive lifting and dropping of a hammer.

Acting on these facts, several manufacturers went into the production of hand rock-drills which could be operated by turning a crank. Unfortunately, however, most of them made the great mistake of trying to produce a drill which would compete with power-drills in regard to rapidity of drilling; the result being that it required so much effort to operate these drills that the men were soon exhausted and the drill was cast aside as worthless. A few manufacturers, however, contented themselves with manufacturing a drill that would compete successfully with other methods of hand-drilling and these drills have been successful. The interior mechanism of the drill consists of but two moving parts, a ram with collars, made in a solid steel forging, and a shaft carrying two cams. The ram is pushed back by means



MAP OF ALASKA. Showing Railroads Projected.

of the cams and, upon the latter releasing, is thrown forward by the action of a heavy spring. The whole, of course, is operated by the turning of a crank which is so geared to the cam-shaft that the drill will strike an average of 3¼ blows for each revolution of the crank. This apparatus is easily handled and yet it is claimed that it will do twice as much work as a man will with hammer and bit, working in the same ground and under like conditions.

One of the principal advantages of these hand-drilling machines is the fact that they can be mounted on a light tripod or column in the same manner as a power-drill, and can therefore be used to better advantage for tunneling, stoping, drifting, etc., the support being rigid enough for the purpose intended yet light enough to permit of easy handling. On this account, and because of their effectiveness and simplicity, it would seem as though there ought to be a large field for this class of machinery.

Personal.

Ross B. Hoffman has gone to Montana.

T. H. Proske, of Denver, Colo., is at Joplin, Missouri.

George S. Binckley has returned to Monterey, Mexico.

Frank C. Loring is examining mines at Cobalt, in Ontario.

Robert Delarge has returned to Berkeley from Prescott, Ariz.

Louis Noble, of Denver, is examining mines in British Columbia.

Arthur L. Walker has returned to San Francisco from New York.

Stephen A. Ionides sailed from New York for London on April 25.

John Eudey has returned to Jackson, Cal. from Sonora, Mexico.

Harold Rickard was in New York on April 20 on his way to England.

Robert J. Frecheville sailed from San Francisco for Japan on May 10.

Blamey Stevens is examining mines in Tuolumne county, California.

R. Gilman Brown is examining mines in Tuolumne county, California.

G. B. Manson is superintendent of the Rincon Mines Co., at Martinez, Ariz.

W. Murdoch Wiley expected to sail from Vera Cruz for New York on May 10.

Walter H. Weed has returned to New York from Cananea, in Sonora, Mexico.

M. W. Hoyle, manager of the Gold Dust Mining Co., Breckenridge, Colo., is in Chicago.

Alexander Burrell has left Berkeley, returning to Helena, Mont., where he formerly lived.

J. H. Mackenzie has abandoned his contemplated expedition to Alaska for the present.

A. H. Keller is engaged in metallurgical work at Santa Rosa de Copan, in Honduras.

Frederick B. Reece, having graduated from the University of California, has gone to Utah.

A. F. Hewitt, of Hewitt, Carstraphen & Co., Denver, Colo., is in Arizona on professional business.

Harold A. Titcomb has returned from Central America and is now on a visit to New Orleans.

Frederick Grundy has returned to Los Angeles from a professional trip to the Cerbat district, Arizona.

Ellsworth Daggett, of Salt Lake City, is manager of the Nevada Co., with mines at Austin, Nevada.

W. W. Wishon was burnt out by the fire; he has taken his family from San Francisco to Los Angeles.

John J. Daly was at San Francisco during the conflagration; he has returned safely to Park City, Utah.

George W. Gilmore, treasurer of the Mohawk Mines Co., Denver, is at the mine near La Plata City, Colorado.

H. R. Plate, of Denver, has gone to Ely, having been appointed manager for the Nevada United Mining Company.

E. D. McDermott, who lately has been in Arizona and Colorado, sailed on the 'Nippon Maru' for Japan, as assistant to R. J. Frecheville.

J. Langeloth, president of the American Metal Co., Ltd., New York, passed through San Francisco on his way from Cananea to Granby, B. C.

At the annual meeting and dinner of the Pittsburg Lehigh Club, on the evening of April 21, Charles L. Taylor, who is allied with the Carnegie interests and who is a trustee of Lehigh, announced a gift from Andrew Carnegie of $100,000, to be applied to the erection of dormitories at Lehigh University. This is the first large sum that has ever come to Lehigh from other than alumni of the university of the men identified with its founding.

Obituary.

Henry Williams Parkhurst, past president Western Society of Engineers, Member of American Society of Civil Engineers, died April 7th from injuries sustained on Feb. 20, 1906, in Chicago. He was born at Boston, Mass., June 25, 1847.

Samuel Williams, of El Paso, was killed by Yaqui Indians in Sonora, Mexico, on April 15. A telegram from Hermosillo states that the party, with which Williams was traveling, was ambushed; he was assayer with the Giroux Consolidated Mining Co., at Carbo, Sonora.

George Lansell died at Bendigo, Victoria, on March 18. He was the best known mine-owner in Australia and one of the most enterprising citizens of that Commonwealth. As the owner of the 180 mine, for many years the deepest gold mine in the world, he won a deserved celebrity, for he was the pioneer of deep sinking at Bendigo. Thirty years ago, when wild speculation had brought its usual reaction and when the shallow mines had penetrated below the rich outcrops, Lansell asserted his confidence—and intelligence—by sinking the 180 mine until between 1,560 and 1,870 ft. he penetrated the great saddle reef which made him a rich man. He continued to take a keen interest in mining operations and enlarged the scope of them until he was the largest mine-owner in Australasia. The 180 mine is now yielding profitable ore at 3,310 ft. below the surface. Beyond his success as a speculator, he was a public-spirited citizen and did more than his share to build up and to beautify Bendigo. At Fortuna he had a lovely home, the gardens of which were made on the old tailing heaps from his stamp-mill, and there he entertained travelers from every part of the world. The house, with its statuary and fine paintings, was alongside the stable and that in turn came next to a 32-stamp mill, the noise of which, to the old miner, was a music only unpleasant when it stopped. He died at an advanced age, for he was over eighty, after a life of great usefulness.

Horace F. Brown, mining engineer and inventor, died suddenly of heart failure on April 15, in Chicago. He was born at Litchfield, Michigan, in 1840, and for more than forty years was actively engaged in mining, and particularly in devising means and ways to constantly improve the prevailing methods. The mining industry has benefited much by the products of his fertile brain. Being honest and honorable in all his dealings, competent to an unusual degree, and an indefatigable worker, he attained a high position in the field of mining and metallurgy. His first work after leaving school was mining in Plumas county, California, in 1862. This led to surveying and other engineering work of like character. It was his good fortune to be associated with a man named Maloy, who was a genius in the way of devising ways and means for doing work under difficulties. As a large part of his life was spent on the frontier, remote from modern facilities for doing engineering work, the training he got from Maloy was invaluable to him. From Plumas county he went to the Reese River district in Nevada, and erected a silver mill for a company from Butte county, California. The mill was a counterpart of those then in use on the Comstock lode at Virginia City, but the Reese River ores were of a totally different nature, so the mill was a failure, and it became necessary to change it to a chloridizing mill. For this purpose hand-rabbled furnaces were erected, and all of the ore was roasted with salt to change the silver to chloride. This was his first experience in complex methods. From Reese River he went to Virginia City, and had a varied experience in silver milling and mining in deep mines. During 1864 he worked in some of the mills of Carson Valley and gained some experience in the erection of special appliances for the recovery of silver. At that time the art was little understood, so that his work was a constant succession of experiments, both as to mechanical appliances and as to chemistry. After some experience in the lead smelting camps of Nevada, he returned East and spent some time in coal mining in Pennsylvania, Indiana and Illinois, in trying to introduce a machine he had patented, which was the first built in the United States of the continuous-cutting type. This device was successful, but he was unfortunate in being a pioneer as there was at that time a strong prejudice, not only among the miners, but among the mine bosses and superintendents as well, against the introduction of machinery for this purpose. He had, however, the melancholy satisfaction of seeing all of the continuous coal-cutting machines now in use built upon the identical line covering his patent, but his patent expired before this type of machinery came into general use, so he never reaped any reward, except some valuable experience. When in Pennsylvania, at the Fall Brook coal mines, he put in the first underground wire-rope haulage system in the State, and met with the same resistance among the miners that he had encountered in trying to introduce the coal-mining machinery. After being badly injured in the mines and having exhausted his resources, he went to Montana and took up metal mining and ore reduction. He was two and a half years with the Hecla Consolidated Mining Co., in Beaverhead county, Montana. These were nominally lead mines, but there was so much copper that both metals had to be reckoned with. At this plant the principal product was lead bullion, but as the ore contained a good deal of copper, quite a large proportion of the metal recovered was in the form of a lead-copper matte. This he was obliged to re-smelt for the purpose of eliminating its lead content, and, in a measure, the silver, and for enriching the copper content. All of the product was marketed in Germany, as no refineries would handle such material in America at that time. On arrival at Hecla he found small primitive smelting furnaces, but he had the satisfaction before leaving of devising and installing some large water-jacket furnaces, the iron work of which was built by Fraser & Chalmers, and which is still their standard for such plants. During his stay with the Hecla company he had charge of all the mechanical work, both at the smelter and mine. Owing to the success of this plant, others desired to copy the machinery, and he left there with the purpose of installing similar works at other points, and was for two and one-half years superintendent of the Alta-Montana Company's plant near Helena, Montana. This property consisted of five mines, one wet concentrator for lead ores, one dry concentrator for lead-silver ores, one 20-stamp free-gold mill, one 15-stamp chloridizing mill, and a 50-ton lead-silver smelter. He made the designs and superintended the erection of this entire plant except the free-gold mill. At this plant he did all the metallurgical work and was directly in charge of the mining development, and in general charge of the concentrators and the free-gold mill, these last two being several miles from the main works. As this was before the days of railroads when all of the salt had to be hauled from Salt Lake City by wagon and all of the bullion sent to Corinne by the same method, one can readily imagine that his duties were varied, and he was obliged to make-shift often to keep the plant running. He finally became so impregnated with lead and arsenical poison that he was forced to leave the smelters and engage in the manufacture and erection of mining machinery, the designing and erection of metallurgical plants, and supervision as consulting engineer of mines. He organized the Western Iron Works corporation of Butte, Montana, and was manager of that plant. While at the Alta-Montana Company's plant, he had become thoroughly impressed with the wasteful and expensive character of the prevailing practice of ore roasting, and busied himself with devising means for bettering the operation. This finally resulted in the patenting of what had been known as the Brown roasting furnace, which revolutionized the practice of ore roasting in reverberatory furnaces. He met the usual fate of successful inventors, and was obliged to go to law to protect himself against infringers of his device. For six years he was engaged in persistent law suits, but he finally prevailed against all of the infringing devices. While he was successful, he found that there was but little left after settling multitudinous claims of lawyers, witnesses and other expenses.

Among other metallurgical devices which he originated was a condensing chamber for the recovery of volatile fume from lead-smelting plants. This device was erected at Omaha, Neb., by the Omaha and Grant Smelting Company. In addition to successful inventions set forth in the above, he designed and built a continuous-working kiln for making carbonic acid gas direct from lime-rock by heat instead of by the use of acids and marble dust. This device was successful and was installed in several cities. With the growth of concentration and the constantly increasing fineness of the material to be treated, the question of the after treatment of the fine concentrate became a serious one. His work in this direction was successful and resulted in patenting what he termed the Brown Down-Draft Smelting Process; a process designed to handle fine materials, such as dust from blast furnaces, iron sand and fine concentrate.

His life was a useful one, his heart a generous one, and to know him was to admire and love him. The mining industry has suffered the loss of one of its most intelligent workers.

Standardization of Mine Accounts.

Written for the MINING AND SCIENTIFIC PRESS by
H. G. NICHOLS.

Although the subject of mine accounts has been much discussed, there is still room, it would appear, for definite conclusions relating to certain important aspects.

Various opinions have been expressed concerning the possibilities of standardizing, in a greater or less measure, a scheme of accounts, and the general decision arrived at would seem to be, that while such a system would be most desirable, the difficulties of correlating the several works of different undertakings, are enough to render more than a general outline or skeleton scheme, such as is capable of modification and expansion to meet the diverse needs, well nigh impossible.

I, for one, would be glad to see this discussion reopened with a view to seeing if it might not be possible to achieve something more in a matter so desirable from the standpoint of technical and financial requirements individually—and for the gain to be derived by more closely defining the relations between these two factors of a mining undertaking.

The last point would be secured by every step that reduces vagueness in, and gives the definite market value to, technical statements. No mine is worked, or is supposed to be, by reason of its technical interest. It is the duty of the engineer to state operations and possibilities according to his judgment, in understandable terms. No opinion is of value which is not based, wherever possible, upon actual figures, and no figures are of value unless complete. Hence the necessity of arranging figures in such a way to represent facts as they ought to be stated and understood in the direction of the operations.

The following notes are submitted in the hope that they may serve to induce some further discussion upon the subject, and, as the outline of a scheme for the standardization of all mine accounts. The aim should be the elimination, ultimately, of all general or indefinite items and the reduction of all the expenses incurred to accounts of a self-explanatory denomination.

Speaking generally, it is necessary to collect all expenses having relation to the several departments, under certain headings and in such a form as to facilitate calculation of cost per unit of the most essential factors; also, to keep distinct, all items bearing on one department; and to include all apportionments of general or special expense in each department.

The system of accounts kept by each milling company at their works, must provide for all expenses being finally gathered together and referred to such explanatory accounts. Further, it is very necessary that a financial scheme should be universally adopted whereby the value of all works and improvements is recognized as being dependent upon, and for the benefit of the operations during a period of time regulated by the conditions existing and which were held to justify the undertaking of such operations at their inception. To use Mr. H. C. Hoover's words "the clothing of dead mines" should be assessed at its proper value—which may be nothing.

To enumerate the points which appear in the scheme:

(1) As stated above, it is necessary to have a set of primary accounts of which there shall be one for each step in the actual operations of ore-getting and treatment.

(2) In-as-much as there must always be individually characteristic works in connection with every property, the ultimate aim of which may be apparent only to those conducting the operations, each individual undertaking must have a set of secondary or department accounts (suitable to its own requirements) of which there must be one for each branch or department, carried on for the benefit of, or common to, possibly more than one primary account; these are to be distributed monthly to, and between, such primary accounts.

(3) There must be accounts which may be called 'special' or 'periodical', dealing with expenses incurred for the benefit of any part of, or all, of the operations that are essentially distributable in point of time benefited, and that are subject to subdivision, to be hereinafter outlined.

To enumerate one more generalization before proceeding to special points which must be provided for, it may be stated that the objects of mining accounts are:

(1) To afford a guide in the laying out of future work.

(2) To afford a means of supplying the home office with such details of work as may enable them to compare results with anticipations, and to shape their financial policy.

The principal requirement in achieving the first is detail, in the second, simplicity.

It is not necessary to enlarge upon the part played by fixed charges in the formulation of schemes for mining work, but as to what constitutes a fixed charge and as to the best way of efficiently segregating it without confusing the accounts, and yet so as to emphasize their individuality—these are points worthy of discussion. The decision as to which accounts must be considered as embodying expenses, the incurring of which is independent of the tonnage—and if not wholly so, then, to what extent—must always remain more or less a matter of judgment, and to be decided only from an intimate knowledge of the conditions. It is not sufficient only to class such outside expenses as those in connection with the running of the office, traveling, administration or legal expenses, etc., as fixed charges, for, it is apparent that there are many items other than these upon which the cost per ton for varying tonnages will not vary in the same proportion. So important is the bearing of these fixed charges on the principles of mining finance that none of such items can be disregarded.

It may be taken as an axiom that all expenses are incurred in order to benefit the working of the property, that the life of a mine is a calculable quantity and that no useless expenses are allowed; therefore, all expenses are ultimately referable to the working accounts in proportion, or in relation, to the time benefited; all regular working expenses are periodically posted to the Primary and Secondary accounts; for the rest, special accounts are divisible into:

(1) Those involving expenditure necessary for the immediate operations, but which still at the same time benefit future periods. These will be called 'Concurrent' accounts:

(2) Those involving expenditure upon works for future operations and having no bearing on existing procedure. These will be termed 'Anticipatory' accounts.

The first class, being necessary to the operations, are operating expenses, but they are not actually wholly chargeable to the month in which they are incurred, and are referable to a Floating General Account, for apportionment without interest.

The second, being by nature Anticipatory, as regard the benefits conferred are, so far as present operations are concerned, paid with borrowed money, and are referable to an Amortization Account. The following table of accounts is suggested as supplying the requirements of financial and technical management.

A. PRIMARY ACCOUNTS.

(1) **Mine Stoping.** Breaking rock in established stopes, and delivering same through shaft or tunnel, to the surface, including the expense of sorting and handling of waste encountered in the stope.

(2) **Mine Stoping Development.** Preparation for stoping an established orebody. Provisions for ventilation in working the stope, and for handling the broken ore.

(3) **Mine Development.** Prospecting, and all work having for its object the establishment of orebodies (the creation of reserves) including all the equipments necessary to the proper operation of such work to that end.

(4) **Mine Hoisting.** Work performed by means of the main hoisting works, in completed shafts or sections of shafts.

(5) **Mine Foremen.** Supervision of mining operations, including salaries of foreman and all officials directly under his orders, such as, time-keeper, storekeeper, shift-bosses, etc.

(6) **Mine Expense.** Repairs and maintenance necessary for keeping existing works open, and maintaining the efficiency of all underground and surface works.

(7) **Ore Transportation.** Delivery of the ore to be treated from the mine depository to that point where the first step in its treatment, or for the benefit of its treatment, is taken.

(8) **Milling.** Handling and treatment of the ore from the time that it is delivered, to the point where it leaves the mill in form of tailing not capable of economic amalgamation or concentration, and including the production, ready for delivery, of amalgam and concentrate; attention to driven mill machinery, and regular wear and tear. (In the mill cost-sheet, this account is divided into 'amalgamation,' 'labor and supplies,' and 'concentration;' concentration dealing only with the work on the concentrator floor.)

(9) **Concentrate.** The removal and subsequent expense incurred in the reduction of concentrate. (By making a separate account for this product, the various conditions that may obtain regarding the treatment of it, are included under one heading, whether it is shipped, smelted, or treated at the works in any other way. There is, of course, a credit as well as a debit side to this account.

(10) **Mill Bullion Product.** The account for returns from amalgamation.

(11) **Tailing Transportation.** All expenses connected with the handling of tailing, from the time that it leaves the mill, until the time that it is received in the tailing treatment plant, or, where no such plant exists, runs to waste.

(12) **Tailing Treatment.** All or any treatment of tailing after it is discharged from the mill.

(13) **Bullion Charges.** The cost of shipment to purchaser, and of sales of all bullion.

In gold mining, the above is suggested as being the scope of the Primary Accounts, and is intended to include every radical step in the undertaking. To these accounts all expenses are ultimately to be referred, whether charged direct, or through the medium of:

B. SECONDARY ACCOUNTS.

(1) **Power.** Carpenters, blacksmiths, fitters or mechanics' shop expenses. Nearly all work done can be charged direct to the Primary Accounts, but the running of shop machinery, and up-keep of tools and the salaries of outside foreman and his officials, if any, should be included in this account.

(2) **Assay Office.** Where retorting and smelting is included in the department of the assayer, a value for each of these operations should be assigned in assay units, and the total expense of the department be distributed between the mine, mill and tailing plants in proportion to the assay units of work done for each.

(3) **Office Expense.** Clerical work. It may be extended to include some work in connection with the store-house.

(4) **Administration Expense.** Technical supervision of the works generally. Surveying is considered to be for the benefit of Administration, and is accordingly held to be chargeable to that account.

(5) **Traveling Expense.**

(6) **Legal Expense.**

C. SPECIAL ACCOUNTS.

(1) **Concurrent.** Taxes, repairs and improvements to running plant (store-house).

(2) **Anticipatory.** Secondary construction new improvements, mine equipment.

D. FLOATING GENERAL ACCOUNT.

Debited with monthly payments of No. 1 and credited with monthly appropriations of each, distributed.

E. AMORTIZATION ACCOUNT.

Debited with monthly payments of No. 2, to which is added interest at a rate to be decided upon and agreeing with that taken into account in formulating the general scheme of which such works are the result, and in pursuance of. This account is credited ultimately by appropriation of increments of profit arising from the new works.

The Question of Development. It will be seen that no Development Redemption account is included in the scheme; on the other hand however there are Development and Mine Equipment Accounts.

The theory followed is that development work is carried out according to a previously arranged programme which calls for a certain reserve. This is the case even where the principal of maximum development is followed, for the reason that whatever the rate of progress, secondary equipment will follow on its heels at proportionate rates; consequently, if development is held to be restricted as defined above, then such work ranks with the other regular operating expenses and may be considered to be in relation to the tonnage.

Other work which may be done for facilitating the working of such reserves after their existence has been established, is, from the standpoint taken, not strictly development, and therefore, a Mine Equipment account is provided for the sinking of shafts through country, to meet, or for the benefit of, established works, the enlarging and secondary equipment of all shafts, the driving of adit tunnels, not having for their object the increase of the reserve body and all such work. This account ranks quite properly with others for the construction of secondary plant, or in other words, 'Anticipatory' account and is referable to the Amortization account in common with them.

It may here be noted that the Amortization account is not distributed among the monthly charges, but is considered in toto as capital expenditure, subject to interest and redemption or amortization out of the profits secured.

Storehouse—It is preferable to consider this account in the light of a parallel or concurrent commercial undertaking run for the benefit of the mining operations.

Fixed Charges—From their nature it is impossible to actually state what these may be beforehand, but the accounts from which they may spring and the cause affecting their occurrence, cannot be too thoroughly understood.

Taking the accounts in the order in which they are stated, items not wholly dependent in their extent upon tonnage, or in other words not varying in the same ratio, may first be found in No. 4 or Hoisting. Both in the cost of labor and supplies, it is apparent that a larger tonnage can be handled under ordinary conditions at a lower rate than can a smaller one. Just what this difference of cost would amount to, might in many instances be stated very closely; but in the majority of instances it must be left to the judgment of those intimately connected with the conditions.

In the next account, Mine Foreman, the saving can almost be definitely assured, it being a comparatively easy matter to forecast just what increase, if any, in the department's staff will be required to cope with the enlarged works.

No. 8, Milling, affords another difficult example; for instance, to assume the case of a stamp-mill having 20 stamps for the operation of which the cost per ton is $1.20. This may be made up of:

Labor, free milling	$0.36	
Mill supplies	0.12	
Power labor	0.20	
Power supplies	0.40	
Concentrate	0.12	$1.20

Here, cost per ton of mill supplies would be subject to no change in the secondary plant of say twice the capacity, the concentrating labor might possibly be affected to a higher degree than milling labor, and the power labor most of all. It is necessary then to distinguish between these items and state them in such a way as to render the calculation of that proportion of them referable to Fixed Charges, as easy as possible.

Coming now to the Secondary accounts, the question of power is one requiring careful handling. For instance, with a small plant requiring 100 h.p. for its operation, the boiler capacity will be on a scale such that a variation of the tonnage requiring a diminution in horsepower of 30% would entail an uneconomic state of things at the boiler, far out of proportion to that brought about by the reduction by a similar tonnage in an increased plant having an output requiring a boiler capacity of say 500 h.p. Generally, it may be stated that the larger the plant, or the smaller the factor of increase, the less need is there for considering power in this respect or to any extent as a fixed charge, but other factors, as, for instance, care and repairs of ditches or flumes must always be so considered.

All the rest of the secondary accounts enumerated, come naturally in toto under the heading of Fixed Charges, and generally it may be stated that that proportion of any cost per ton in connection with any branch whatever of the works which is in excess of what the cost would be, under the conditions of the next secondary equipment, should be included as a factor in estimating Fixed Charges. Thus the decision of this matter is thrown very much upon the judgment of the engineer, and this fact emphasizes the necessity of clearly defining the channels through which all expenses must pass, and lends prominence to the details in practice for making the initial charges, while it does not detract from the advantages secured by the ultimate simplicity of the Primary accounts.

The work at the mine should be so laid out, and the accounts so arranged as to facilitate the segregation of expenses at the earliest possible moment. This means having a responsible head to each department, capable of superintending and checking (from his personal knowledge) the daily apportionments of labor and supplies. The business of time-keeping is thus twofold, being first the registration of the work performed by each man and the total number of shifts worked by all of the employees daily, which must check against the daily segregation or apportionment of the whole cost between the several accounts. This is not difficult of achievement, and with as many as 300 men on a payroll properly kept, entails perhaps half-an-hour's work for the foreman every day. On the regular payroll, in so far as possible, labor for similar work at similar rates should have space to itself. There is small objection to one name appearing in more than one place. Time-books should be large enough to allow of one or more distinctive letters or symbols, referring to accounts, being marked against each shift or fraction of a shift. A form of mine detail sheet to be kept by the foreman is given at the top of this page.

From such a sheet a superintendent is readily able to post the analysed costs in connection with each working place, as required, in his cost minute-book, which is also used for recording the work performed; and this constitutes a useful detailed record of the work. The detailed checking of supplies may also be regulated by distributing the responsibility in a similar way; for instance, in connection with the charging of supplies used in the mine, account must be taken of the necessity of a mine-store through which explosives, steel, etc., are passed, and from which they are dealt out for use in the several working places. In such a store there is always a difficulty in attending to clerical work, and where attempted, it is often unsatisfactory. The system which has been found most satisfactory and reduces the work in the mine store to mechanical routine is as follows: Compartments or lockers, large enough to hold sufficient stores of all the regular mine-supplies are built in the store, one for each account or working place of which separate record is required to be kept, and is labeled with each distinctive name, thus: "Stoping" or "No. 1,No. 2, No. 3, stope"; "Development" or "Main shaft," "No. 6 Level"; "Equipment"; "Expense", etc. On each locker a tag marked with the distinctive name is kept hanging; the general storekeeper also keeps in the main store a corresponding weekly tally-sheet for each working place, made out as follows:

MAIN SHAFT

1906	Powder lbs.	Fuse Feet	Caps No.	Candles lbs.	Sundr's
On hand Jan. 1					
Jan. 1					
2					
3					
4					
5					
6					
7					
On hand Jan. 8					
Consumed					

At the beginning of every week, it is his duty to go to the store and weigh or otherwise check the supplies in each locker, posting them to his tallies. It is the duty of the man attending to the mine-store to keep the lockers supplied with material, and when any article is required, he writes it on the tag, the foreman signs it, and it is sent to the storekeeper who posts the amount given out to the proper date on his corresponding tally-sheet.

In this way confusion is avoided in handing out stores to the employees, while any leakage is quickly made apparent, and a tally is always in the office to be checked against the work done for the week. Thus the superintendent has constantly before him in his minute-book a weekly record of the work done and the labor and supplies expended, by which he may readily compare progress.

As regard work in the main storehouse, it appears to me that a card system is in every way the most suitable. A duplicate set of cards in the following form is kept, and all transactions are posted up daily:

STORES

CANDLES

Date	Amt.	Deatails	Price per Unit	In	Out

Date	Supplies	Cost	Cost
Jan. 6	40 lbs. Candles	4 40	

As stated at the outset, it is not sought to lay down rules with reference to the details of book-keeping, or even to claim superiority for any one method of collecting and posting expense-details at the mine. The main object sought is the clearer understanding of technical relations with regard to mining operations. It would seem that in the matter of defining technical responsibilities, half the battle would be fought, were the issues represented in mutually understandable terms; while a standardization of accounts would go far towards promoting this end, it would also assist materially by affording a better means of comparison by which both the conduct of technical operations and financial business would be facilitated.

Thickness of Water Pipes.—Pipes subject to uniform constant water pressure can be made much lighter than those subject to water hammer and to varying pressures due to starting and arresting the column of water as in the discharge pipe of a single reciprocating pump. Again, pipes which lie on the ground and which are not liable to be disturbed can be made lighter than those which, like the column pipes in vertical shafts, are subject to strains from being forced out of line by moving ground. Corrosive action of the mine water may also require extra thickness. All strains and destructive influences must be taken into consideration in designing a line of pipe, especially in mines where delays are nearly always expensive. The column pipes for underground pumps are, therefore, usually made several times the strength that would be required for a pipe line operating under constant pressure. What applies to strains in discharge pipes of pumps, applies, however, with greater force to such power pipes as are used for operating reciprocating hydraulic engines, because here the shocks are liable to be even more severe than in the case of pumps. The discharge pipes of centrifugal pumps are not so liable to water hammer and can therefore be considered in the same category as pipes subject to uniform pressure.—HANS C. BEHR.

Special Correspondence.

LONDON, April 25.

From Messrs. Bewick, Moreing & Co.'s report on the Great Fingall Mine for 1905, it appears that disappointment has been experienced in the continued shortening of the main ore-shoot and its much lower value at the No. 11 and 12 levels; although the ore in sight shows an increase of 131,799 tons over the previous year, the grade is lower. At the same time the reappearance of values in the No. 2 winze below No. 12 level (the deepest working on the line of the main shoot) and also the discovery of a branch from the main reef at the No. 4 level south are encouraging features. The No. 13 level will be driven as rapidly as possible into the region of the main ore bodies. During the year the main shaft was sunk 216 feet to a total depth of 1,532 feet, and altogether 7,983 feet of development work was done, resulting in the opening up of 335,116 tons of ore. The 100-stamp mill was run continuously during the year and treated 203,317 tons of ore, producing 159,798 oz. fine gold, valued at £681,728. The working expenses, including development, averaged 19s 9.3d, as compared with 19s 8.02d per ton in the previous year. Following the system adopted for economical working, a larger quantity of ore was broken in the stopes than was extracted. The total tonnage of such ore at December 31 aggregated 167,744 tons, representing an expenditure of £38,498, which amount stands charged to suspense account pending the extraction of the ore. The profit and loss account shows a net profit for the year of £451,556.

Another West Australian company, the Ivanhoe Gold Corporation Ltd., has issued its report for the twelve months to December 31, 1905. It states that the expenditure on mine development, buildings, plant and equipment, amounting to £59,612, has been written off in pursuance of the policy recommended by the board and approved by the shareholders in 1901. The total expenditure on these items since the formation of the Company, amounting to £637,314, stands in the balance sheet at the sum of £54,295, the amount of the company's original working capital. A further reduction in costs has been made. The working costs have been reduced to 19s 4.69d per ton, while the total West Australian costs, including the whole of the mine development, and the ordinary expenditure on buildings, plant and equipment, work out at 23s. 10.21d. per ton, a gradual reduction having been made during the last five years which began in 1901 with £1 11s. 8d. and £2 6s. 10d. respectively per ton of 2,000 lb. Including a final distribution of 9s. per share now recommended, the dividends for 1905 amount to a total of 24s. per share or £240,000, bringing up the grand total, during the existence of the company from February, 1899, to £1,510,000. The general manager's report shows that the 100-head mill ran 351 days during the year for a duty of 5.6 tons per stamp per 24 hours at a cost of 3s. 0.39d. per ton, including rock-breaking, transport and concentrating. The fine-grinding plant now consists of 15 pans, 12 taking the coarse product from the 100-head mill, and three being used to take any escaped sand from these twelve. The pulp that finally leaves the mill shows 1 per cent. on 40-mesh. The cost per ton of grinding raw sand works out at 1s. 0.48d. The quantity of concentrates now being saved by 34 concentrators and 14 slime tables is about 40 tons per day, and when the full complement of the latter are installed it is estimated 45 tons will be saved. The classifiers feeding the Wilfleys have been modified considerably, with good results. All the concentrate is now delivered into a pump, and is lifted to the settling vats over the roasting furnaces, thus avoiding the former shoveling and tucking. Four Edwards furnaces are employed full time in roasting concentrate, and an additional one is on order to cope with the increased quantity produced since the slime-concentrators started. During the year 10,960 tons were roasted, recovering 22,897 oz. fine gold, showing an extraction of 96 per cent., for a total cost of 12s. 11.4 per ton, the loss in residues being 1.80 dwt. During the year 95,275 tons of sand were leached by double treatment, producing 23,656 oz. of fine gold, showing an extraction of 65 per cent. of gold contents in this particular product, at a treatment cost of 1s. 9.7 per ton, the loss in residues being 2.73 dwt. In the slime treatment the filter-presses accounted for 90,334 tons, yielding 38,981 oz. fine gold and giving an extraction of 83 per cent. of the gold content, the loss in residues averaging 1.86 dwt. per ton. Bromo-cyanide is still being used in this department, where the total costs amount to 6s. 7.79d. per ton.

With regard to the extraction, the report states that the total tonnage amounted to 196,569, producing bullion containing 125,590 oz. fine gold and 35,604 oz. silver, the particulars of gold extraction being shown in the schedule below:

Fine gold won from	Total yield oz.	Yield per ton dwt.	Extraction per cent
Mill	40,056	4.075	27.06
Sand	23,656	2.407	15.98
Slime	38,981	3.966	26.33
Concentrate	22,897	2.330	15.47
Fine gold extracted	125,590	12.778	84.84
Loss in residue		2.282	15.16

In connection with the experiments made during the year the new Wilfley slime-tables had attention, and it was on the results of these that it was decided to install a number. The ordinary Wilfley concentrators are stated to have a tendency to lose a large amount of fine concentrate and the slime-tables are to be used in conjunction to arrest this loss. At the end of December there were fourteen of these working, and it is believed the effect should be noteworthy henceforth. In the mill, tests have been made on the various mesh of screens to determine the most suitable as regards tonnage and extraction. The most efficient screen was found to be about 225 holes per square inch, the concentrating being affected by any coarser mesh, with the result that a large proportion of mineral escaped the first row of Wilfley tables in coarse particles of sand, which, on entering grinding pans, was to a slight extent ground too fine for the slime-tables to catch, thus escaping to the sand and slime-plants. Finally, the ore reserves, above the 1,203 ft. level, amount to a total of 769,060 tons (of 2,000 lb.) and average 13 dwt. 23 gr. Including this company's shares, the Westralian market showed some activity last week, influenced partly by a cablegram from Great Boulder Perseverance announcing the cutting of the Lake View Lode at the 1,300-ft. level assaying 14 dwt. over a width of 9 ft. A favorable cable was also received from Great Boulder Main Reef stating that the diamond drill in the hole No. 3 in the north drive at 160 ft. had located the main lode orebody 40 ft. to the west, the width averaging 12 ft. for 14 dwt. per ton.

Under its heading of 'City Notes' last night's 'Globe' gives some pertinent reasons from its own point of view why Australian gold mines do not now command one tithe of the attention which British speculators and investors paid them a few years back. In the 'Globe's' opinion this apathy must have largely contributed to the decline which is noticeable in the Australian gold output. In round figures, the total output of West Australia, Victoria, Queensland and New Zealand fell off in 1904 by 100,000 oz., and in 1905 by another 100,000 oz., and a further decline is anticipated for the current year. It is pointed out that Broken Hill is very much to the fore at present, and the falling away in the gold industry is probably attributable in part to the increased attention which is being given to silver and base metals; also that unwise legislation in some of the colonies has imposed great hindrances on gold mining, and seriously discouraged the genuine prospector. But at the root of the whole mischief, the 'Globe' believes that 'Westralianism' will be found. The British public are sick of the market methods of the 'shops'—very few exist now, the majority having found that there are no customers for the wares on sale—and refuse to embark further capital. Under these circumstances, there is no demand among promoters for Australian properties. With the stream of British capital thus summarily checked, it is not remarkable that the volume of gold production should show a notable diminution year by year.

As a sign of the times the 'Financial News' has taken up the parable of Cornish mining. It asks: "How comes it that a little speck of England out of which the best authorities estimate £50,000,000 worth of copper, tin, silver and lead has been taken in the past two thousand years should relatively lie derelict and abandoned? Where there ought to be 200 to 300 properties at work —for the present prices of copper and tin would make almost any sort of Cornish mining proposition payable —a beggarly 13 companies are working, probably, a little over 20 mines. To the cynic the reason for the decay of Cornish mining is as plain as the nose on his face. They are too near home. Could they be but transferred to Thibet, the globe would probably ring with their richness. Distance often lends enchantment to the view in mining enterprise. Klondyke, with its golden creeks, far away on the border line of the Arctic Circle, could not fail to attract; Rhodesia, under the sway of a barbaric ruler, offered all the enchantments of a place out of the ken of civilization. But Cornwall! Can it be expected that a bit of sea-coast famous for its rocks, its cockles, and its shrimps can be associated in the public mind with still untold, undelved mineral wealth?

In an attractive retrospect some of the familiar scenes of by-gone days are brought back to the memory of veteran 'cousin Jacks.' Among the mines referred to are the Bottallack, worked for tin fifty years ago, making a profit of £300,000. On the point of being abandoned, in 1841, a rich course of copper was struck. The capital expended on this property returned in dividends five or six times over. The Balleswidden tin mine, also in the St. Just district, which returned £59,600 from 1833 to 1841; and the Levant tin and copper mine making in eight years a profit of £150,000 and employing 600 persons. The Boscowell Downs tin mine, which gave the adventurers, out of a single bunch of tin, between £15,000 and £20,000 in the course of a few weeks. The St. Ives Consols tin mine successfully worked for over 30 years, very rich in tin. The Wheal Vor mine is mentioned as having the first steam-engine ever erected in the county, between 1710 and 1714, and which employed 1,200 persons with at one time 15 engines in use. The Godolphin tin and copper mines which made a first profit of £50,000, and after being idle from 1836 to 1841, was taken up again and about £40,000 expended. The Great Wheal Fortune, which made a profit of £100,000.

As a matter of course the Devon Great Consols is not overlooked. It is described as the most astounding romance connected with the history of west-country mining. The narrator states that upon calls aggregating a little over £1,000 it paid in dividends, during its career, sums exceeding £3,000,000. Its £1 shares rose to over £800, and, astonishing as that may seem, they were dealt in on the London Stock Exchange as a humdrum investment, yielding at that price a very liberal return. The mine was originally worked as a copper mine, when the £1 shares were about £100 apiece in market value. In taking out the copper ore the arsenic underlay was left exposed; so when it became profitable, as it did, to work the arsenic, mining was carried on without practically any cost for development.

So much for the past glories of the 'old county' as recorded in the up-to-date 'Financial News.' Dealing with latter day events the 'Mining Journal' announces that : The first of the flotations of the Cornish Consolidated Tin Mines, Ltd., (see my Correspondence of April 11), is now practically settled, and will take the form of converting South Wheal Crofty from the cost-book to limited liability. The authorized capital of the new company will be £50,000, in shares of £1, of which about £35,000 will be available for working capital. Of this latter sum, £25,000 has been guaranteed. The directorate of the new company will include Mr. Francis Allen (Chairman of Clitters United and the Cornish Consolidated Tin Mines), chairman; Mr. Frank Harvey (Chairman of Dolcoath Mine), vice-chairman and Mr. R. Arthur Thomas (Manager of Dolcoath Mine), director. Two other directors will bring the number of the board up to its limit, viz., five members. The deal, whilst an exceptionally good one for South Wheal Crofty, will be equally advantageous to the Cornish Consolidated Company, who have early shown their knowledge of the industry by picking one of the few properties which, with judicious development, should in a short time become one of the large producers of the district. As it is proposed not only to push development energetically, but also to equip the mine with the latest and most up-to-date machinery, Crofty's output, of roughly, 25 tons per month, should within a reasonable period be at least doubled. This, under present metal market conditions, means something like 50 per cent. dividends on the capital engaged, and, according to the 'Mining Journal,' as the Cornish Consolidated will be holding about 25,000 shares in the new company, of which only 40,000 are to be issued, the possibilities for Cornish Consols—especially with other similar deals to follow—can hardly be over-estimated.

BUTTE, May 5.

An eight-hour work day has been adopted at all of the Amalgamated mines in Butte, and affects 10,000 men. For several years the miners have been working but eight hours for a shift, going to work on their own time that is, they reported at the mines half an hour before working time and were required to be at their places underground promptly on the hour. Beginning with the first day of May the men went into the mines on the company's time, making a difference of half an hour in favor of the men. At the same time the eight-hour day was made to apply to all other employees of the Amalgamated Co., who had been working nine and ten hours. The change will mean an annual difference to the company of about $600,000. The concession was voluntarily granted by the company, the new rule applying as well to smelters of the company at Anaconda and Great Falls. In making the announcement John D. Ryan, managing director, stated that the Amal-

gamated Co. is out of politics and has no favors to ask and no enemies to punish.

New companies continue to be organized to explore for copper in Butte district. A scheme is projected to explore the mountain range east of Butte district. It has long been the opinion of local mining men that at depth there are copper deposits in the mountain, but the heavy cost of sinking to the necessary depth has always deterred men from exploring there. Now, however, the demand for copper is considered sufficient to justify the venture, and owners of claims on the mountain are organizing a company to run a tunnel near the base of the mountain to demonstrate whether there are paying copper veins there.

Ten carloads of machinery for the new hoisting plant at the Leonard mine of the Boston & Montana Co. have arrived. The engine is a duplicate of that recently installed at the North Butte, and is designed to work to a depth of 3,500 ft. Above 1,200 ft. the Leonard has been producing a large tonnage for many years. It is still one of the rich mines in the district above that level. For several years the East Colusa mine was worked through the Leonard shaft, but is now again being operated through the old Colusa shaft, because the Leonard is not equipped to handle the ore rapidly. The shaft on the West Colusa mine is being sunk from the 1,600-ft. point to 2,000 ft., which will give 400 ft. additional stoping backs. Owing to lack of lumber the Boston & Montana Co. closed the Pennsylvania mine three days last week, but a plentiful supply is on hand and the mine is working to full capacity again.

The Butte-Northern Copper Co. is driving a tunnel and sinking a shaft on its property north of Walkerville. The tunnel is in 60 ft. and the shaft is down 55 ft. Oxidized copper ore is coming from both workings. The property is in the neighborhood of the mines of the Butte and Bacorn company.

F. A. Heinze has sold all of his interest in the Davis estate mines to J. A. Coram, who is organizing the American Consolidated Copper Co. This disposes of the report that he will be associated with Mr. Coram in the flotation. Mr. Coram says Mr. Heinze will hold stock in the corporation, but will have no other interest in it. Mr. Heinze's interests in Butte district are now limited to that of a stockholder of United Copper, Butte Coalition, and whatever interest he will have in the Coram company.

The Afro-American Mining and Milling Co., with a capitalization of $200,000, has been organized by Butte and New York colored men, including Charles F. Jones, of Butte. The company owns five mining claims in the northwestern portion of Butte district, and six in Madison county.

The main shaft being sunk by the East Butte Mining Co. has reached a depth of 400 ft., at which point a pump station is being cut, a large amount of water having been encountered. It is expected the shaft will reach a depth of 500 ft. early next month, when crosscutting will begin, while sinking continues.

Among the new companies recently organized, exploration work is being done by the Butte & London, Butte Copper Exploration Co., Butte-Milwaukee Co., East Butte Extension, Butte Copper Co., Butte & Bacorn, Butte Hill Copper Mining Co., Butte Northern, the General Development Co., Bullwhacker Mining Co., and the Calumet & Butte. A score of others have not yet started work.

Arthur C. Carson, general manager of the North Butte Mining Co., has also been made general manager of the Butte Coalition and Red Metal Co. interests in Butte, while George E. Moulthrop, for many years connected with the Boston & Montana Co. as foreman of the Pennsylvania mine, has been made general superintendent of the Red Metal operations.

A deed conveying from Thomas F. Cole all of the United Copper properties in Butte to the Red Metal Mining Co. has been filed for record in Butte. A release of the $2,500,000 mortgage on the property of the Nipper Consolidated Co., one of the United Copper concerns, has also been filed.

The Pittsburg & Montana Co., since its smelter has been shut down, has been shipping 100 tons of ore per day, to the Washoe smelter at Anaconda. It is probable this will continue for a long time, and that the Pittsmont smelter will not soon be rebuilt, as it has been found that the company can more economically have its ore treated by the Washoe. There is a move on foot to reorganize the Pittsburg & Montana Co., pay off its debts, amounting to nearly $2,500,000, and put the company on a firmer basis. The company has mines capable of yielding 300 tons of ore a day, but for three years or more they have been doing little else than experiment with a new smelting process.

The East Butte Copper Mining Extension Co., organized recently, has bought the Westlake mine, situated between the Pennsylvania and Belmont mines. Although the shaft of the Westlake is only 200 ft. deep, the former owner took out $200,000 above that depth. The company now has half a dozen small mines, and is sinking a central shaft, which has reached a depth of 70 ft. The manager, Mr. Cooney, expects to reach a depth of 200 ft. by the first of June. At that point a station will be cut.

The Butte-Milwaukee Co. has added the Florence and Stonewall claims to its holdings in the North Butte district. The Florence has a 70-ft. shaft and a vein 25 ft. wide, from which considerable ore has been mined, carrying $7 to $10 silver and gold per ton. The company will develop the Florence. The group now comprises the Pollock, Colonel Sellers, Bird, Comstock, Stonewall and Florence. The Butte-Milwaukee also owns seven claims in Argenta district.

The Frank Moulton mine, a silver property owned by one of the W. A. Clark companies, is to be re-opened. The property has not been worked since 1893, but a number of lessees have taken it and have put up a new hoisting plant, and retimbered part of the shaft. The shaft of the Moulton is down 900 ft. and contains 200 ft. of water, which is being pumped out. The Moulton carries two classes of ore—silver-gold and zinciferous. Both will be mined, and the zinciferous ore will be sold to the Montana Zinc Co. The vein is the same as that passing through the Alice mines of the Butte Coalition company.

The Butte-Hercules Copper Co., one of the recently organized concerns, has let a contract for sinking a 200-ft. shaft on the Key West, one of the eight claims owned by the company, and located about a mile southwest of Butte. The company succeeded to the interests of the old Silver Bow Mining Co. and acquired others.

DENVER, May 4.

The American Mining Congress is proceeding with plans to have its own building in Denver. About two weeks ago a plan was formulated to raise funds by the issuance of bonds. It was figured out that by erecting a semi-commercial building the rental of stores and offices would easily pay a low percentage on the investment, say 3 to 4 per cent, and it was thought easier to sell low interest-bearing bonds to interested parties than to secure outright gifts. Then again it was planned to let all the rentable space to representative mining and metallurgical interests, so that these headquarters would become the central beehive of mining industry. The plan, as briefly outlined above, was submitted to the Committee of Mines and Mining of the Denver Chamber of Commerce some two weeks ago and was endorsed by them. I am glad to learn that the plan has been dropped. It appears that both D. H. Moffat and Simon Guggenheim disapproved of it; both of these gentlemen have agreed to contribute liberally to the building, so I understand, and both are united in the idea that it must be kept free from all commercialism. As I understand the aims and objects of the American Mining Congress, they are to foster the interests of the mining industry, to promote and originate legislation favorable to mines and mining and to protect the vast army of small mining investors as far as possible. It can readily be seen that the object last mentioned might be seriously endangered if the officers of the Congress were more or less at the mercy of their tenants to get the money to meet the interest on the bonds. Mr. Moffat declares that headquarters must be built purely by donations, and I think the mining fraternity will agree with him.

The directors have decided to hold the ninth annual meeting of the Congress in Denver, extending from November 13 to 17, inclusive. The directors appointed the following committees: Program—E. A. Colburn, Denver; E. A. De Lavergne, Colorado Springs; V. C. Alderson, Colorado School of Mines; C. Willard Hayes Washington, D. C.; Edward H. Benjamin, San Francisco. Building—D. H. Moffat, Denver; E. A. Colburn, Denver; A. J. Spengel, Denver. Transportation—Samuel F. Dutton, Denver; A. G. Brownlee, Idaho Springs; Edward J. Wilcox, Denver; H. J. Sieman, Denver; J. F Callbreath, Denver. Membership—E. G. Reinert, Denver; E. A. De Lavergne, Colorado Springs; J. F. Callbreath, Denver. Finance—W. F. R. Mills, Denver; with authority to choose associates. Drainage districts—D. W. Brunton, E. Lyman White, F. J. Campbell, R. S. Morrison, E. A. Colburn, all of Denver. Building construction—J. H. Richards, Boise; E. A. Colburn, Denver; Thomas Ewing, Vivian, Ariz.

Few people have any idea of the mineral richness of the Clear Creek Basin. There are six mines in that district that have declared more than a million dollars each in dividends. Mines that declare a million in dividends are rare and the people of Clear Creek are a resourceful people. For instance, Idaho Springs and Central City both have their own iron works, which supply practically all the repairs and a good part of the original installation of all the mills in the basin. They have their own dairies and raise a large part of their own garden truck. Every town has its own butcher shop, supplied with mountain-raised beef, and one man at Forks Creek is starting an angora goat herd to gather profit and sustenance from the steep side hills where cattle cannot thrive. Idaho Springs has wagon factories, harness factories and many other little industries that tend to keep the miners' money at home. The saw mills of the basin supply nearly all the lumber used in the district and practically all the mine timbers come from the adjoining forest-clad hills, but perhaps the most advanced of all the local industries is the utilization of water power. All this internal development is along the lines that experience has shown to be the best stimulant to a flourishing mining industry, but unfortunately the very spirit which has made Clear Creek basin more nearly self-sufficient than any other district in the State has also bred a clannish feeling which disdains the value of advertisement and outside technical knowledge, and treats the outsider with precious little consideration. This spirit is, however, fast disappearing under the leadership of such progressive spirits as J. J. Sherwin of Idaho Springs, George Stewart of Alice, Col. Desch of Georgetown, Lieut. Charles Ripley of American City and Mr. Renshaw of the Gem mine at Idaho Springs. Chief among the new enterprises originated lately by one or the other of these gentlemen may be mentioned the enlargement of the United Hydro-Electric plant at Georgetown, the building of new wagon roads and the crystallization of railroad plans to serve the James Peak country, the intelligent investigation of the milling problem at Idaho Springs and the advertisement of the Clear Creek basin by the Idaho Springs Chamber of Commerce. The enlargement of the United Hydro-Electric plant consists of the installation of one 750-h. p. Pelton wheel, direct connected to an electrical generator and a 500-kw. Parsons-Westinghouse steam turbine and generator. The reservoir capacity will also be greatly increased; altogether $100,000 will be spent and nearly all of this money is advanced by the local people.

This electric power plant at Georgetown has been a great stimulus to the mining interests of upper Clear Creek. The five mills (four new ones) at Silver Plume are all run by power from this plant. The Scotia Mining & Milling Co. at Silver Plume have just let a contract for their mill. When this mill is completed Silver Plume will be milling 400 tons daily. The Dives-Pelican people are now building a tramway; when this is completed they expect to enlarge the capacity of the mill.

The Argentine Central railroad is an enterprise backed purely by mining capital, and I am told it already shows that it will be even more successful than the Gilpin County tram line, which was the first local enterprise of the sort. This new railroad starts at the Colorado Southern tracks and winds its way up the rocky hills toward East Argentine. Ten miles of it was completed last fall and materials are even now on the way to extend it five miles this summer. E. J. Wilcox was the moving spirit in this enterprise, and his mines, the Waldorf Mining Co.'s properties, will furnish the greatest tonnage, for a time at least.

A strike has just been made on the Little Mattie, which illustrates most forcibly two remarks that I have recently made respecting this part of the country, namely, the disdain for engineers and their ways and the reduction of mining costs due to advance of mining and milling methods developed very largely in Denver. The Wild Rose claim was owned from 1885 to 1894 by J. J. Sherwin and associates. They had some good practical miners working for them and knew that these miners had opened up some ore having a value of about $25. No maps of the property were kept. The keeping of exact records is not Clear Creek style. The men who were putting up the money were of the opinion that the amount of $25 ore opened up was comparatively small, and besides, ore of that grade was not much good at that time. So the work was stopped and later on the shaft caved in and still later it was sold to the Little Mattie Co. for a small sum. This week some lessees got the shaft cleaned out and timbered. Mr. Curtis is one of the lucky men. They find already blocked out enough $25 ore to put all interested in the lease on easy street. Moral for those 'putting up the money': Employ an honest and intelligent engineer.

Around Idaho Springs there is too much going on to tell this time. I will just mention a few points of interest. The most important event is the starting up of the Newhouse tunnel. I don't know anything about this scheme from the sockholder's standpoint, but from the standpoint of a local citizen the enterprise is of inestimable value to that great mineralized section lying

between Idaho Springs and Central City. I understand the tunnel lies 2,000 feet under the summit of Seaton mountain and about 1,000 feet under Central City. To my mind the great value of this enterprise consists of the enormous territory it makes available for easy prospecting. Developed ore they say is about as cheaply hoisted as trammed out of the tunnel, but there is no comparison between prospecting drained and undrained territory. It is said the Newhouse tunnel will be pushed to the California vein this time without cessation of work.

The people who own the famous old Saratoga got tired of waiting for the tunnel to drain their mine, although the vein is being worked through the Newhouse tunnel, so manager John Owens has started unwatering from the surface and has also been considering putting some diamond-drill holes up from the Newhouse. It is said that the principal motive in this work is the fear that a human life or two might be sacrificed if the flooded workings of the Saratoga were tapped by a raise, before the pressure had been relieved somewhat by other methods. Corporations are not always so considerate of matters outside the profit and loss columns. It would obviously be cheaper to stand a damage suit or two for miners killed than to unwater the Saratoga from the surface. At the present time the Saratoga and the Sun and Moon are drifting eastward from the tunnel, while the Old Town, Gem, Addudel, Queen, Jackson Leasing and Orr Mining Co. are driving or have driven west.

A few more brief notes and I must close. The Hoosac tunnel has resumed and cut a rich vein. The Lucania tunnel, on Fall river, has struck enough ore to make Judge Colburn wear one of those "smiles that won't come off." The Comstock people say they have 200,000 tons of $6 ore developed. Pretty big order, that! The Two Brothers has opened an ore-shoot that has "millions in it," so they say. The Big Five Central, in drifting on the Shafter vein has opened up so much ore that I won't put in print what the owners think about it. We have all heard of the world's tail and the down-hill pull before. The Burns-Moore and the Honest John discoveries up Chicago creek are of importance, because both indicate the extended mineralization of a large series of strong veins. The Burns-Moore strike is the most substantial of the two as far as developed at this writing. The Rockford Bore has cut ore of smelting richness, but I will keep the rest till next week. I hope some time in the near future to give the readers of the Mining and Scientific Press a somewhat accurate account of the bodies of low-grade ore developed recently in the Clear Creek basin. All I can say at present is that as far as I have seen and heard this district is going to surprise the State with its low-grade production in the next few years.

DENVER, May 7.

A strike in the Mammoth mine at Leadville has caused considerable speculation in view of the trend of the ore-shoot, as it does not seem to be connected with any of the known orebodies in that locality. The trend of the ore—northeast by southwest—would seem to show its connection with the large shoots of Fryer and Carbonate hills; it trends toward the Canterbury hill, and this fact has aroused new interest in that vicinity. A large body of ore has already been disclosed by the shaft, sufficient to demonstrate that the ore exists in an unusually large body; it assays about 130 oz. silver and 30% lead per ton.

Mr. Hoyt, manager of the Ross smelter at Silverton, has made several successful runs, producing a 55% copper matte. On account of the closing of the roads to the mines by snow, the smelter has been temporarily shut down for lack of ore, and will be started up again as soon as the roads are opened. This enterprise means much for San Juan county, which is capable of producing a large tonnage of low-grade copper ore, such as cannot carry the burden of freight and smelter charges. It is the intention of the Ross company to increase the capacity of the plant up to the tonnage obtainable.

Mr. Reece C. Vidler, manager of the Transcontinental Transportation and Mining Co., has returned from London, and is pushing the Vidler tunnel at Argentine with renewed vigor. He has purchased an air-compressor, of 1,200-ft. capacity. This will replace the smaller one at the tunnel. Other and heavier machinery is to be installed.

The Crescent mine, of the Bull Hill Development & Mining Company, at Cripple Creek, is increasing its output. Recent development work has disclosed a greater extent of ore, and of higher grade. The mine is now producing about 100 tons daily, the output being limited by facilities for handling. On April 28 a station was started at the 700-ft. level, from which a drift will be run to cut the ore at that depth. The company is preparing to install a heavy hoisting plant and an aerial tramway to transport its ore to the Sovereign switch.

The Marsh and Hodges lease on the Little Clara claim of the Work Co. promises to be one of the biggest strikes made in Cripple Creek for a long time. The ore was encountered by a 50-ft. raise from the Ophelia tunnel, following a rich seam which led to the 'flat vein' of Gold Hill, from which the Mary McKinney produced a large amount of ore. The orebody has been opened for a thickness of nine feet by 50 ft. long and 50 ft. laterally, without reaching its limits. The ore is said to carry five ounces of gold per ton, as sampled in the mine. Through the average grade appears streaks of nearly solid sylvanite three and four inches wide.

Notwithstanding the closing of a number of the Cripple Creek producers, it is claimed that the April output of that district, not yet published will exceed that of any month since November, 1905. All the sampling works have been run at full capacity.

It is reported that fair-sized veins of ore, valued at $5 to $20 gold per ton, are being opened in the South Park district, near Hartzell, on the Colorado Midland railroad. For a number of years past, considerable prospecting has been going on in that section, but though the ore was fair, the veins were small.

The Doric Trust, of London, England, has sold the Doric tunnel, near Georgetown, to the X-Ray Mining Co. The X-Ray company controls the Magnet group of mines on Saxon mountain, and the tunnel is a valuable addition to the economical operation of the mines. The heading of the tunnel is now into the Magnet ground, a distance of over 3,000 ft. from the portal. The Magnet group is said to have produced between one million and two million dollars' worth of ore. The tunnel cut several pay-veins, but no driving to speak of has yet been done on any of them.

Several months ago Bernard J. O'Connell, of Clear Creek county, sent a signed article to the Denver 'Daily News' directed against the Smelter trust. Mr. O'Connell again returns to the attack and cites the case of a miner who shipped 28½ tons of lead to the Trust smelter, and states that according to the schedule for Clear Creek district, after deducting freight and treatment, the miner should have received $1372; instead he received $570. Mr. O'Connell invites Simon Guggenheim of Denver to an open discussion of the question, and Mr. Guggenheim invited Mr. O'Connell to attend a private discussion of it. In a recent letter, Mr. O'Connell raises the question whether the amount said to have been withheld from the miner is collectable by law. Aside from the political animus of his letters, Mr. O'Connell has opened a question of interest to miners everywhere. The complaint is general and of long standing, and small shippers, particularly, have never been able to figure out from the smelter schedule, treatment charges and freights, what their settlement checks would be on any given grade of lead ore. The question is older than smelter trusts, and a remedy has long been sought. It is quite likely that the Trust could be legally compelled to return the ore, but what the courts would do with the extra amount claimed for the ore is worth finding out.

BUTTE, May 1.

The Butte Commercial Copper Mining and Development Co. is the name given a new corporation organized in Butte which is trying to interest Eastern capitalists in financing the enterprise. The company is one of several score of new companies organized on options on undeveloped mining claims far from developed mines.

Thomas F. Cole has transferred all of the United Copper properties, the title to which stood in his name since the settlement of the copper war between Heinze and the Amalgamated Company, to the Red Metal Mining Co., a New York corporation. The latter is the operating company formed when the Butte Coalition was organized by Mr. Cole and Mr. Ryan. The transfer includes all the mining interests mentioned in the deal with Heinze, but the property is subject to a $1,000,000 mortgage given by the Montana Ore Purchasing Co. and one for $2,500,000 given by the Nipper Consolidated Mining Co., both Heinze corporations. It is understood that the transfer concludes the deal by which the Red Metal and the Butte Coalition become owners of all of the United Copper properties in Butte. A few days ago, by stipulation of the attorneys, the receivership of the Snohomish and Tramway mines was terminated and all matters that had been in controversy between Heinze and the Butte & Boston Company were decreed as settled. The Butte Coalition and Butte & Boston will now operate the two mines which were shut down by the litigation for a number of years. The Nipper mine, another big property for many years under injunction, will soon be operated by the new owner.

The Butte Hill Copper Co. is making good progress in developing its extensive holdings in the new district north of Walkerville. The shaft is being sunk in a vein from which fine bunches of copper ore have been taken.

The Butte & Bacorn Co. is operating in the same neighborhood and has three shafts working. The new hoisting plant has been put up on the Colleen Bawn claim and the company has started crosscutting at the 100-foot level. The men interested in the Butte & Bacorn, including a number of Amalgamated officials, have the utmost confidence in the property. If they are successful in their search for copper in that portion of the Butte district it will add many miles to the mining ground of Butte.

The April production of copper from the mines of the Butte district amounted to 30,842,400 pounds. The output of ore was about 424,800 tons, a little less than 4 per cent copper, or 80 pounds per ton of ore. Preparations are in progress for a largely increased output by the Amalgamated, North Butte, Butte Coalition, East Butte and Raven companies, and it is likely that the monthly production of copper will shortly reach 35,000,000 pounds. The following table gives the averages in ore tonnage, yield per ton and gross daily yield during April:

	—Ore—	——Copper——	
		Lb.	Total
Name of company.	Tons.	per ton.	lbs. daily.
Boston & Montana	3,700	70	259,000
Anaconda	4,000	68	272,000
Butte & Boston	650	60	33,000
Washoe	500	63	31,500
Parrot	560	68	38,080
Trenton	520	80	31,200
North Butte	950	130	123,500
Butte Coalition	1,600	65	104,000
Clark's Original	800	75	60,000
East Butte (lessees)	200	90	18,000
Raven	80	110	8,800
Miscellaneous	700	70	49,000
Total	14,260		1,028,080

The following table shows the total ore tonnage and total copper output in pounds for the month:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana	111,000	7,770,000
Anaconda	120,000	8,160,000
Butte & Boston	16,500	990,000
Washoe	15,000	945,000
Parrot	16,800	1,142,400
Trenton	15,600	936,000
North Butte	28,500	3,705,000
Butte Coalition	48,000	3,120,000
Clark's Original	24,000	1,800,000
East Butte (lessees)	6,000	540,000
Raven	2,400	264,000
Miscellaneous	21,000	1,470,000
Total	424,800	30,842,400

The Cable Consolidated Mining Co., operating the Cable mine, the biggest gold property in Montana, has installed a lot of new equipment at the mine and is hoisting daily a lot of good ore which is treated at the company's mill.

The shaft which the Butte Copper Exploration Co. is sinking on the Six O'Clock group in the northeastern part of the Butte District, has reached a depth of 500 feet. The company will sink to 1,000 feet before crosscutting.

A strike of copper ore has been made by lessees in the Bertha mine on the east side, near the property of the Pittsburg & Montana Co. The Bertha is a small triangular piece of ground, but a vein 15 feet wide has been opened and 30 tons of ore are shipped from it daily, the ore running about 7 per cent copper. It adjoins on the west the Pacific mine of the Butte Mines Exploration Co. The Pacific is well developed and the only apparently good property in the Butte district that has remained idle during the present boom in copper and copper properties. The principal stockholder is a Baltimore brewer, who put up money for its development five or six years ago, but he grew tired of the speculation and shut down the property. Since then nothing has been done with it.

The mines of the Raven Mining Co. are showing up better as development progresses. The company is hoisting 80 tons of ore a day, during the course of development, and ore is being blocked out.

An alloy with which it is claimed aluminum may be soldered is composed of seven parts of aluminum and one part tin.

MINING SUMMARY

ARIZONA.

GILA COUNTY.

(Special Correspondence).—Mine development in the territory west of Globe, between the Black Warrior mine and the east line of Pinal county has been rapid. Several of the mines opened, have become important shippers. The Live Oak leads in shipments, sending out 125 tons daily, the ore going to El Paso and Douglas and some to the Old Dominion smelter at Globe. There are 40 teams on the road hauling ore from the Live Oak, where there are 300 men on the payroll. Joseph C. Erman is superintendent, but the property is being worked by Boon & Strange, lessees. Their lease has nearly eight months still to run and it is estimated that they will clean up a quarter of a million dollars by the time it expires.

Globe, May 2.

MOHAVE COUNTY.

(Special Correspondence.)—Owing to the failure to obtain sufficient wood for the Pyramid mill, in Signal district, W. C. Howard, superintendent, has contracted for fuel-oil, some of which has been delivered. Hereafter it is proposed to use fuel-oil at the mine and mill, and as soon as a larger supply can be received, the mill will be started up on ore from the Kathryn and Sheep-trail mines, as well as from the Pyramid group. Several hundred tons of ore are now on hand and the stopes are opened sufficiently to insure a supply for eight or ten months.

W. H. Cushing has returned from Kansas City, where he purchased a 100-ton mill for the De la Fontaine mine at Stockton hill. The mill will be shipped from Kansas City and will be erected on the Cupel mine, one of the group belonging to the company of which Mr. Cushing is superintendent. The two mines will keep this plant running for a year or more without opening up any new ore, there being 40,000 tons in sight in the De la Fontaine alone. In the Cupel there are large orebodies that can be handled in the mill. At the 380-ft. level of the De la Fontaine the east drift is in concentrating ore. The drift has been driven into this orebody 35 ft. and the ore is improving. It is six feet wide. In the west drift from the same level the orebody is somewhat broken, but good ore appears all through the vein. The water is at this level and is slowly rising.

Kingman, May 1.

YAVAPAI COUNTY.

(Special Correspondence).—O. B. Marshall, who is developing a group of claims in Big Bug district, states that his shaft is now down 90 ft., and that the ore is better than at the surface. W. L. Roberts is exhibiting in Prescott a large quartz specimen glittering with gold, which was taken out of a claim recently discovered by him on the Skull Valley slope of the Copper Basin divide, about three miles from the Derby mill. After making the discovery ten days ago, he commenced to run a tunnel on the vein and now has seven tons of ore on the dump, with a 20-in. vein in the face that will mill over $50 per ton in free gold.

Prescott, May 4.

YUMA COUNTY.

(Special Correspondence.)—Allan J. Smith, manager of the California King Gold Mining Co. writes to Capt. Polhamus, at Yuma, that he and Mr. Doak will arrive in Yuma the latter part of the week, prepared to start work on the property as soon as the supplies and tools can be moved to the camp. The California King property is a gold proposition at Picacho, and is owned principally by Joe Mendiville, Allan J. Smith and Capt. Isaac Polhamus. The ore is low grade, but there is a large body of it, and it can be worked profitably on the scale of operations which the owners have in view.

Yuma, May 3.

CALIFORNIA.

NEVADA COUNTY.

C. H. Mallon, Superintendent of the Brunswick mine near Grass Valley, has placed an order for lumber for a 20-stamp mill.

PLACER COUNTY.

J. R. Nickerson has sold his group of claims on Rock Creek to the Guggenheim Company for $60,000. The mines are at present flooded but are to be unwatered and development extended. The ore carries copper.

SAN BERNARDINO COUNTY.

A gold and copper strike has been made near Kelso, along the Salt Lake railroad. Twelve miles southwest of there, in the Winston Basin, among the Providence mountains, several parallel ledges averaging $40 gold per ton, and running high in copper, have been uncovered.

The ledges for three miles have been located, sixteen prospectors having united their interests in the properties, who propose to develop several of the claims, with the expectation that a permanent mining district will result.

SIERRA COUNTY.

(Special Correspondence):—It is reported that the Sierra Buttes Company is negotiating for the purchase of the Biglow mine, which is supposed to be the same vein as that in the Sierra Buttes. The Sierra Buttes Company report having enough ore in sight to keep their 60 stamps going for years. The mine has been producing for more than 50 years.

The Bullion mine under new ownership expects to soon begin active operations.—— The Keystone, or Sierra Alta has resumed operations and will soon start the mill. Fred Pennyman is Supt.—— The Marguerite expect to complete their drain tunnel soon.—— The Cleveland is reported running on good ore.—— The Sovereign is still doing development and have a large body of good ore.—— The Empire, in Gold Valley, had to hang up their mill for a short time owing to accident to the dynamo. They have been running on rich ore recently.—— Robert Nisbet has purchased the O. A. Edholm mine on the North Fork. This is a combination of quartz and gravel. He has a force on development.—— The Telegraph is sinking an incline on some deep gravel in the old channel. They expect to get to bed rock in a week.—— Peckwith & Spaulding at the West Point Mine took out two $50 nuggets last week and also made a good clean-up of fine gold. This is a continuation of the White Bear Channel.—— The Last Resort is driving on the ledge, which prospects well.

H. L. Johnson has begun development on the Eldorado ledge which in the past has produced some large pockets.—— The Tightner has been installing an electric hoist.—— The Oriental has resumed operations with twelve men.—— A new tunnel is to be run from Oregon Creek to tap the ledge in the American Flag Mine, which will give them 1000 ft. of backs. This is owned by Messrs. Jackson, Hathaway and Meek.—— Work at the Alaska is progressing. They will sink the new shaft 700 ft. before crosscutting. The old shaft was only 450 ft. deep and stopped in rich ore on account of water. The management will install electric power.

Downieville, May 5.

SISKIYOU COUNTY.

On Butcher Hill, a mile north of Yreka, gold has been discovered in stringers exposed in a cut dug for a railroad. Hydraulicking is in progress on Little Humbug Creek. The water from the creek is raised by centrifugal pump and the stream used in washing the gravel. At Quartz Valley and Oro Fino the hydraulic mines are in operation, with abundance of water available. The quartz mines of that district are also in operation. The Morrison and Carlock mine is working steadily at Quartz Valley. Sinking is in progress and the upper levels are being developed.—— On Indian creek the Golden Eagle mine is reported yielding steadily and satisfactorily. During March $4,000 were taken out with three stamps. Howard Lewis is Superintendent.

The Yreka Journal says the hydraulic mines on all the small streams tributary to Klammath river, from the mouth of Scott river to Humboldt county, are working gravel. By breaking surface hardpan with powder the giants are able to move a large amount of material daily, with good profit.

Near Oro Fino it is reported that Frank Quigley has recently sold 55 acres of his farm for dredging purposes.

The Wright and Fletcher claim at Oro Fino is running with giant and elevator. Eastlick Bros. are opening up the Wilson tract, and the proposition is reported to be a success. Two giants are employed in piping.

Frank Starr is getting out rich ore for his arrastre, which he will operate during the summer.— The Medina Mining Company is preparing to put on a crew to clean out their ditch. They expect to cut the vein at any time. The work of prospecting and development continues.— Hydraulic elevators will be placed on the Ethelynn mine on Horse Creek near Oak Bar. The gravel is three feet deep and can be worked by elevators better than in any other way.— At the mouth of Empire Creek, Klammath river, Carter and Taylor are drifting on bedrock.— I. O. Harrison is to mine under the race track one mile south of Yreka, where bedrock is thought to be 100 ft. deep with pay gravel 4 to 10 ft. deep.— John Garvey has been preparing to work his placer claim on Klammath river by means of hydraulic elevators.— Harvey Bowerman has a lot of ore out at the Wild Irishman mine, near the King Solomon mine and will commence milling as soon as he can pack the ore to the mill.—Ladd and Patton are working their quartz claim on Horse Creek and have cut their ledge 60 ft. deep, and drifted 50 ft. each way on it. The vein is 18 in. wide and will mill $30 per ton. They expect to build a mill.— The Canon Mountain Co. owning the King Solomon mines are putting on a larger force and getting ready to build a wagon-road from Black Bear to the mine. They will build a stamp mill and cyanide plant.— Simon Cauzetti is developing his quartz claim at Board Tree gulch in Salmon River district, with promising prospects. He will put in a small mill this season.—— The Salmon River Mining Co. is working the Petersburg claim night and day. They made a good clean-up last month.

COLORADO.

CLEAR CREEK COUNTY

(Special Correspondence.)—Some of the mines around Georgetown are handicapped on account of the condition of the roads, while others are in a position to make their usual production. Work is progressing as rapidly as possible in the East Argentine and indications point to a busy season in this particular district. The Capital Milling & Transportation Co., situated close to town, is driving a tunnel 180 to 200 ft. per month, and, at the rate they are now working, expect to reach the Colorado Central belt by the middle of July. The tunnel is now in 3,200 ft. Wm. Cooper is manager.

Georgetown, Colo., May 5.

(Special Correspondence.)—It is reported that the Scotia Mines Co. operating in this vicinity will erect a small mill for handling the product from its mine.

The Corry Mining Co., C. S. Desch, resident manager, is expected to install a new mill during the summer.

J. H. Eaton, manager the Dives-Pelican mine and mill, states he is now handling 150 tons of material per day through his mill at a cost not to exceed 90c per ton for mining and milling. He is erecting an aerial tramway to handle the material from the old Pelican dump to the mill.

It is reported that Dr. Burt, of this place, is now in the east securing money to place a plant of machinery on the old Smuggler group of claims. He recently organized the Maine Gulch Mining, Milling & Transportation Co. for operating the Smuggler claim on which he has a lease.

Silver Plume, Colo., May 4.

The Brighton mine at Freeland has received part of its new electrical equipment and the remainder is being hauled to the mine. The shafthouse, which is 18 x 36 ft., has been completed. The plant includes a Westinghouse induction motor, direct-connected, about 75-h. p., and a 16 x 18 Leyner air compressor; a 20-h. p. motor is also to be installed, to operate by gear connection, and a three-plunger electric pump.

Regular shipments of milling ore of the Dover-Brighton mill are being made, and to facilitate ore sorting a large grizzly and additional ore plats are now being built. Development work is being carried on with double shift, and with new equipment additional air drills will be employed for mining 50,000 tons of ore, varying in grade from milling to smelting, now blocked out in the mine. The levels west are penetrating new and better territory, the contour of the mountain giving additional depth as the levels are extended.

LAKE COUNTY.

The Rawlins mill, of the Boston & Arizona Mining & Milling Co. at Leadville, are ready to start up and will handle ore from the Fanny Rawlins, which carries gold and silver, lead and zinc. The mill is supplied with all of the up-to-date machinery and is driven by a 40-h. p. motor. The mill has a capacity of 50 tons per day and will turn out a clean product of concentrate.

LA PLATA COUNTY.

(Special Correspondence.)—As soon as the weather will permit it is expected that a large amount of work will be undertaken in La Plata district. The May Day is one of the big producers of the county and the indications point to a larger production than ever. It is expected the railroad will be completed in time for summer traffic from the main line of the Denver & Rio Grande to the mine. This will facilitate matters materially. A few miles farther up the gulch the Tomahawk Mines Co. is preparing for extensive development of what was formerly known as the Little Jane. The

Little Jane Co. was organized several years ago and several thousand dollars spent in developing and prospecting the property. After a time work was abandoned, and the president of the company, Mr. E. H. Lunken, of Cincinnati, Ohio, refunded all the money that was paid in by stockholders. Since then the property has been idle. In the meantime a thorough examination of the property has been made and it was thought advisable to reorganize the company and start operations anew. Former stockholders were given an opportunity of taking stock in the new enterprise. The new company is managed by E. H. Lunken, president, Cincinnati; F. T. Henry, secretary, Denver; G. W. Gilmore, treasurer, Denver; D. M. Forker, director, Pittsburg, and Julius Uihlein, director, Cincinnati. A large air compressor will be installed, when work will begin on a long tunnel. In some places snowslides do considerable damage. The past few months the power plant of the Bonnie Girl mine was put out of commission by a huge slide near the town of La Plata.

La Plata, Colo., May 1, 1906.

SUMMIT COUNTY.

(Special Correspondence).—The Laurium mine has been sold by Niles & Walker, to a company which intends to double the mill capacity and put on a large force; this mine, which is situated on Nigger Hill above Illinois gulch, is well opened up and has a large quantity of milling ore developed. The Hamilton mine in Summit gulch has been leased to a party of capitalists by the owner, A. W. McFarlane, of Denver. George C. Forsythe of Breckenridge has returned from a protracted stay in the East, and reports good progress in the financial affairs of the Coyne Mining & Milling Co. which has valuable holdings on Peak 1, of the Ten Mile range, and Mr. Forsythe says that various development work will be started as soon as the snow disappears sufficiently to enable the commencement of operations.

It is reported that the Briar Rose mine on Peak 10, of the Ten Mile range south of Breckenridge, will be worked within the next 60 days. This property was bought last fall by the South-Western Brokerage & Investment Co. of Memphis, Tenn. This property carries high-grade silver ore and will be added to the shippers' list.

William H. Baker, general manager of the Gold Pan Co. and other officers of the staff in Breckenridge, have returned from Denver, where they met in consultation with the financial branch of the company and report that the Gold Pan is to be worked this year on a large scale.

T. A. Brown, of Breckenridge, has leased the Leona, Edna and Lone Bug claims on Nigger Hill to Condon and Shoock who are already working several other paying leases in this camp. The Rochester group on Bald mountain, comprising Rochester, New York and Buffalo claims, has been bonded to an eastern syndicate and work will be started within 30 days.

The spring thaw is making it difficult to haul ore, and the condition of the roads is causing many properties to cease shipping and consequently a large reserve of ore is now piled on several properties. The Bullion King, on Gibson Hill, has 150 to 200 tons high-grade zinc ore in pile, and by the time the roads are in condition to haul, this quantity will be doubled. The Sallie Barber, on Nigger Hill, has a batch of 40 or 50 tons high-grade zinc ore ready for transportation. The Country Boy mine also has a considerable pile of 40% or better zinc ore ready for shipping and has in the workings a three-foot ledge of ore of the same quality. The Wellington mine is making regular shipments of lead and zinc ores of good grade for smelting and is now hauling the lower grade to the Old Union Mining Co's. mill to be concentrated. The Old Union mill is now running continuously on its own and Wellington ore.

A good strike of high-grade zinc ore assaying 41% zinc has been made in the main tunnel on the Old Union vein underneath the Montgomery shaft. The ledge is over two feet wide. Condon and Shrock are now working their new lease on the Edna and Leona group, on Nigger Hill, and are taking out a good grade of gold ore. This is oxidized ore and is free milling, averaging in value from $60 to $80 per ton. The Reliance gold dredge in French gulch is running full speed day and night and great returns are looked for from the rich channel known to exist at the junction of French and Nigger gulches. The management has been added to at the Lucky mine. Mr. S. H. Dunlap has been installed as manager and will devote all of his attention to this property. George E. Moon is still in charge of the work and has put on an extra force of miners. The Baird brothers are doing good work on their lease at the Dunkin mine, on Nigger Hill, and while developing are taking out some good silver-lead ore carrying gold. It is reported that work will shortly be resumed on the Finding deep shaft. The Mountain Pride mine in Illinois gulch is to resume operations and a tunnel started to tap the main ledge of the property, which during its last term of working produced at the rate of 2,000 per month from the shaft. The Knorr group in Summit gulch is to be worked again during spring and summer and will be started on the first of May. Colonel Lemuel Kingsbury, general manager of the Summit Banner Placer Mining Co. in Breckenridge and of the Buffalo Placer Mining Co. at Dillon, has returned to Breckenridge from the East and is making preparations to start up operations at both properties as soon as possible.

Breckinbridge, May 6.

TELLER COUNTY.

A strike is said to have been made on the Jack G. claim, of the Doctor-Jack Pot Consolidated, on Raven Hill, in a 40-ft. shaft. A streak of ore, 6 in. wide runs five to six ounces per ton.

A strike is reported by the lessees operating on School Section No. 8, known as the Montague lease. A vein carrying from three to five ounces gold was encountered in the shaft during the course of sinking. The vein which was cut at a depth of 625 ft. is from two to three feet in width. This lease has produced a great deal of good ore and has paid handsome royalties into the State treasury. Two cars are being sent out each month by John Best, operating the Jefferson claim. The mineral runs $40 gold per ton. Best is breaking ore two feet wide at a depth of 300 feet.

A lease has been granted to Ralph and Charles Beaman, of Goldfield, on the dump of the American Eagle of the Stratton Estate, and the lessees will begin active operation at once.

Morrell and Butler, leasing on the Accident claim, on the west slope of Gold Hill, have opened 18 in. of ore that gives returns $50 gold per ton. Regular shipments are expected from the property.

NEVADA.

CHURCHILL COUNTY

A new gold strike of importance is reported on a claim at Fairview, and the rush already on to the new camp, has been greatly increased. The strike was made on the property owned by Kerby, Davis, Webber and Hodson. While working on the principal claim of a group, miners uncovered an 18 inch streak of ore going $3600 gold per ton. This streak is in a ledge five feet wide.

NYE COUNTY.

Determined to stop the practice of claim jumping popular with many in the rush to the Nevada gold fields, 200 citizens pressed their way into the merchandise store and saloon conducted by W. A. Gray in Rhyolite on the 15th inst. and demanded that he remove his monuments and destroy his location notices on the Salt Lake, Buffalo and other claims, in the vicinity of the town of Rhyolite. The mob gave no warning of their intentions till Gray was met. For a moment he hesitated to give an answer to their demands; then made a flat refusal. The miners took him in hand and jostled him from one to another until the street was reached. Gray was treated in a manner that soon caused him to agree to the demands of the crowd. Accompanied by his two sons he was escorted to the property in dispute, and the mob saw to it that every trace of the Gray adverse claims was removed before they released him. He was warned that a repetition of the offense would mean something more serious than the experience through which he had passed. Gray's explanation that his action in staking these claims followed legal advice did not satisfy the crowd, and they refused to accept his protestations of innocence.

Three months ago Manhattan had only a dozen tents and not more than a score of people. Today it is a bustling city of 1500 tents and houses, and a population of more than three thousand. Japs and Chinese are excluded by the labor unions, which control the wage scale, and wages are good. Cooks receive $7 per day; waiters $4 and board; bar tenders $7; miners $4.50 and $5; blacksmiths $8; laborers $4.50. The cheapest living to be had costs from $60 to $75 per month, but by buying a tent and "batching" one can live for less. Wood is plentiful and can be had at $6 per cord; water for $1.50 per gallon. Good water is reached at from 40 to 60 ft. depth. Ordinary lumber costs from $75 to $90 per thousand. Lots on the main business street range in price from $500 to $5,000 and ground rents from $50 to $200 per lot. An office room centrally located, brings from $50 to $75 per month—just one. One or two room cabins rent from $25 to $40 per month. Rents for small business houses range from $150 to $600.

Few of the mine owners have done anything more than the ordinary assessment work, and therefore little of the district has been developed.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence.)—As the result of an action to foreclose a mortgage for $60,000 against the Mountain Lion mine and mill, Judge Whitson has handed down a decision in the U. S. Circuit Court at Spokane, Wash., in favor of Albert McLaren against the Mountain Lion Gold Mining Company and awards the complainant a decree for principal, interest, costs, attorney's fees and taxes paid on the property under mortgage. The defendant resisted the foreclosure on the following grounds: That on Aug. 18, 1903, the defendant executed a note for $60,000 payable on demand; that subsequently the board of directors of the defendant company passed a resolution authorizing the taking up and cancelling that note and the execution of a new note, together with a mortgage on the company's mine and mill at Republic camp, to secure its payment. That was not done, but instead, a mortgage was given to secure payment of the original note. The specific grounds of defence were that there was no authority for giving the mortgage, inasmuch that it was not in pursuance of the resolution of the board of directors; that there was no consideration for the company and that the company was insolvent at the time the mortgage was given. The ground was taken that the complainant did not hold the note at the time the mortgage was given, but had endorsed it to the Bank of Montreal. The officers of that bank had testified that they looked to Mr. McLaren for the payment of the note and that he had subsequently taken it up and brought suit to foreclose. The Court held that while there was no express authority by the board of directors for executing the mortgage, yet there was authority for securing the debt, and that it subsequently came to the knowledge of the directors that the mortgage was given, and with such knowledge they had permitted the complainant to rely thereon for over eighteen months in place of repudiating the action of the directors. The Court also found with the complainant that at the time the note was executed and the money advanced it was agreed that the mortgage should be given and that this constituted a sufficient consideration. The Court further held that there was not sufficient evidence of insolvency.

During the last operation of the mine at least 38 carloads of ore were shipped to the smelters, and a considerable lot treated at the mill. It is generally supposed that the agents of the company who contracted the debts, have received sufficient money from the ore treated to, at least, pay the debts contracted on the last run, but they have not yet shown any disposition to settle them, or pay anything. The laborers and some others who furnished supplies have already filed liens. The mine is considered one of the best in the camp, and it is possible that the lien holders may go into court and ask that a receiver be appointed. In the light of events some doubt has arisen as to the success of the concentrating tests at the mill, but those who conducted them say that they have money to put up for the purchase of machinery to treat the ore, if they can get a lease of the mine.

The Quilp mine, after shipping a thousand tons of ore under contract, has closed down for want of a market for more.

At the Pearl Consolidated, by raise and winze, connection has been made between the lower tunnel and bottom levels, and new stopes are being opened. Only three carloads of ore have been shipped during the past week, but the quantity may be increased. Wm. M. Crummer has resigned the superintendency and A. C Cook has been appointed in his place. The installation of new machinery and surface improvements having been completed, the working force has been reduced to 12 men, and the company now hopes to make the mine self supporting and no more assessments will be levied, if possible to avoid it.

At the Copper Key mine ore was struck 20 ft. above No. 2 tunnel level in considerable quantity, and the raise has gone up in it 20 ft. or more. The strike was made on a contact of trachyte and dolomite. This ore runs $20 gold per ton, and carries a small percentage of copper. The working force has been increased by putting on a night shift.

A drift is being driven from No. 2 crosscut, along the hanging wall on the west side tunnel level of the Oversight mine. The crosscut tunnel on the east side has been driven to the vein where there is now considerable shipping ore in sight. A 200-ton ore bin is being constructed in anticipation of transportation facilities near at hand.

The Anonymous tunnel is reported to be in 190 ft. and a stringer of good ore encountered. It is expected to cut the main vein at a depth of about 250 feet.

The Belcher mine is employing 12 men, with one large and one small electric drill in commission, and a raise is in progress between the third and second tunnel levels.

The rolling stock of the Belcher Mountain Railway has been removed from the Washington & Great Northern track to the Belcher Mountain switchback and tracklaying is about to be started.

Meteor camp, on the south half of the Colville Indian reservation, is unusually active, according to a mining man from there. Work has been resumed on the Horseshoe mine. On the New York mine a drift has been driven 150 ft. on a good quality of ore.

The tunnel on the Nonpariel is in nearly 800 ft. and it is believed to be close to the main ledge. It has already crossed two blind veins, the ore from which assayed from $25 to $600 per ton, gold and silver.

A tunnel is being driven from Stray Dog canyon for the Raspberry group which is in about 160 ft. and has intersected a good vein of gold and silver ore.

The Orion Mining Co. is driving a tunnel on a fine group of claims and expects to put it in 1000 ft. or more. It is now in about 600 ft. Eight men are employed. This company has located 1,180 acres of land on the Columbia river, as placer, and intends laying out a townsite. It has commenced building a wagon road from its mines in Stray Dog canyon to the river and has planned the establishment of a ferry across the river, with a view of building a road on the Stevens county side to the Spokane Falls and Northern railway, at Orient.

The Blue Bell Belcher Mining Co. has filed articles of incorporation with Charles S. Voorhees, R. A. Hutchinson, E. C. Grove, George Foster and C. E. Mitchell of Spokane, Wash., as trustees. The object of the company is to acquire and operate the Blue Bell group of claims on Belcher Mountain, believed to cover 3,000 ft. of the Belcher vein, northeast of the Belcher mine. The Blue Bell people claim their boundary to be only 75 ft. from where the Belcher company is now working.

The Washington & Great Northern Railway Co. has ordered 50 new steel 50-ton, self-dumping ore cars for the transportation of ore from the mines of Republic camp and the Belcher mountain neighborhood.

The Keller and Indiana Consolidated Smelting & Development Co. states that its smelter at Keller will be completed about May, 1906.

The Orion Mining Co. is planning for the installation of a concentrating plant at its mines in Meteor camp, Ferry county, Wash.

Republic, May 3.

BRITISH COLUMBIA.

YALE DISTRICT.

Following are the ore shipments of the Boundary mines, in tons, for the week ending May 5: Granby mines, Phoenix, 15,027; B. C. Copper Co., Mother Lode, Deadwood, 3,232; Dominion Copper Co., Brooklyn-Stemwinder, Phoenix, 3,201; Rawhide, Phoenix, 297; Sunset, Deadwood, 858; Emma, Summit, 502; Providence, Providence, 60; total tons, 23,177.

Smelter treatment for the week was: Granby Co., 15,032; B. C. Copper Co., 3,573; Dominion Copper Co., 4,422, total for week, 23,027.

The April output from the mines of Boundary district holds up the 1906 average notwithstanding that the Granby Co. has been running light, owing to repairs and enlargements going on. During the month the mines sent out 107,000 tons. Since the first of the year the tonnage output has been as follows: January, 104,378; February, 105,429; March, 112,638; April, 107,798; total for four months, 430,243.

Granby's output for April was 68,503 tons; B. C. Copper Co., output, 17,668 tons. This smelter must close in a short time for extensive enlargements. The Dominion Copper Co. output for April was 20,000 tons. The several mines shipped ore in April as follows: Granby Co., 68,503 tons; B. C. Copper, Mother Lode 17,668, Emma 1,360, Dominion Copper, Brooklyn-Stemwinder 14,622, Rawhide 1,049, Sunset 4,331, Rambler 35, Strathmore 80, Preston 20, Providence 60, Skylark 70; April total, 107,798.

Notices of Recent Patents.

Dewey, Strong & Co. have offices at 10 Bacon Block, Oakland.

Among the patents recently obtained througr Dewey, Strong & Co.'s Scientific Press, United States & Foreign Patent Agency, the following are worthy of special mention:

CHECK-BACK ATTACHMENT AND CLAMPS FOR TEAMS, No. 818,792. April 24, 1906. Theodore Schmeiser, Davisville, Cal.

This invention relates to a device which is designed for attachment for teams of horses for the purpose of checking such horses in teams as are inclined to travel too freely and to thus equalize the pull of the entire team. This device consists of the combination with a check-rein of a U-shaped clamp adapted to fit and inclose the bight of the check-rein, a screw-shank passing through the sides of the clamp and the rein, said screw having an open loop or head, a single rein having one end attached to said loop and the other extending diagonally rearward and connected to a portion of the draft apparatus.

PILE AND LIKE CLAMPS, No. 818,794. April 24, 1906, Phil Sheridan, Berkeley, Cal.

The object of this invention is to provide a means for steadying and guiding piles, and particularly hollow piles which are built up of staves and of larger diameter, running from three to five feet. The device comprises pivoted horizontally opening and closing clamping timbers having concaved faces adapted to fit about the sides of the pile, metal strips forming shoes for the concavities of the clamps, said strips having their contact faces made convexed in vertical section and pivoted pawls or stops having notches adapted to engage the outer edges of the clamps between the timbers to hold them in position.

SAWING MACHINE, No. 817,628. April 10, 1906. J. A. Cumminskey, Cloverdale, Cal.

This invention relates to an improved machine for sawing wood into suitable lengths and sizes for burning in stoves, furnaces and the like. The object of the invention is to provide a simple, practical, portable machine of large capacity which can be moved readily from place to place and be ready for work at an instant's notice, and which can take logs or poles of any length up to two feet, more or less, in diameter, cut them to the proper lengths, and, if desired, convey the lengths to splitting devices, and which splitting devices are operated from the same source of power used to drive the saw.

APPARATUS FOR MOLDING GLASS ARTICLES, No. 817,576. April 10, 1906. F. J. Mackin, San Francisco, Cal. Two-thirds assigned to Illinois-Pacific Glass Company of San Francisco, Cal., a corporation of California.

This invention relates to an apparatus for molding glass articles, and especially hollow articles, such as jars, bottles and the like. It consists in the combination of pivoted mold-sections, a slotted support therefore, means for shifting the pivot of the mold-sections co-ordinately with the opening of the mold, a slotted disk, projections on the mold-sections engaging the slots in said support and disk, the slots and the support and disk co-operating with said projections to open or close the mold-sections on the operation of the disk, and means for operating the disk, said slots arranged so that one mold-section is given an initial opening movement in advance of another; and other details of construction.

FRUIT PACKING DEVICE, No. 818,812. April 24, 1906. F. K. Bartholomew, Campbell, Cal.

This invention relates to a device for packing prunes and other dried fruits. It comprises in a device for packing dried fruit, a main box or former having one open side, a false bottom and side fitting the main box and completing its outline, a frame substantially fitting the top of the main box having downwardly-extending flange fitting over and temporarily locking the supplemental side and bottom in place, and means by which the fruit with which the structure is filled is compressed into the main box.

Books Received.

The Missouri State Bureau of Geology and Mines has issued Vol. IV of the 2nd Series, on the Geology of the Granby area, by E. R. Buckley and H. A. Buehler. This is a careful study of the zinc-lead field of the Granby area, in Newton county, which lies south of the better known Jasper county in which is the Joplin field. The area in question is 16 miles southeast of Joplin. The publication is handsomely illustrated and contains much valuable information for those interested in the mining of zinc and lead. E. R. Buckley, State Geologist, Jefferson City, Mo.

Commercial Paragraphs.

The temporary San Francisco agency of the Sullivan Machinery Co. is located at 1010 Washington St., Oakland.

J. N. McLeod, assayer and chemist, has moved his offices to 1734 Glenarm St., from 1747 Lawrence St., Denver, Colorado.

The Lunkenheimer Co., of Cincinnati, Ohio, one of the largest manufacturers of high-grade engineering specialties in the world, have on May 1, 1906, opened a well-equipped branch store at 66-68 Fulton St., New York.

The National Wood Pipe Co. announce that their factory at 6th & Channel St., San Francisco, was but slightly damaged and they will commence work again as soon as authorities will allow them to fire-up their boilers.

The Samson Mfg. Co., Denver, Colo., have received orders through Fairbanks, Morse & Co., Denver, Colo., for ten Samson crushers for shipment into Boulder county, Colo. The crushers are being manufactured by McFarlane & Co.

J. W. Duntley, president Chicago Pneumatic Tool Co., sailed for Europe on May 3 in the interest of the company's business. Several contracts are reported by the Consolidated Pneumatic Tool Company, Ltd., London, a foreign branch of the Chicago company.

Announcement is made of the opening of a branch office in Columbus, Ohio, by the Power & Mining Machinery Co., Milwaukee, Wis., in Rooms 700 and 701 Columbus Savings & Trust Bdg., with William A. Heartt in charge as district manager.

The Power & Mining Machinery Co., Milwaukee, Wis., report having recently closed contracts for their Loomis-Pettibone gas generating plants for an aggregate of approximately 12,000 horse-power. Over 150,000 h. p. capacity of Loomis-Pettibone plants have been installed, and are now in operation in this and foreign countries.

Abner Doble Co., with temporary offices, 2611 Broadway, Oakland, Cal., announce that they have now under construction large and new permanent shops and warehouses at Seventh and South streets, in the Potrero district, San Francisco. By May 15 they expect that part of their manufacturing establishment will be running full force, and within a very few weeks the entire plant will be in complete operation.

The Colorado Iron Works Company reports the following shipments of milling and smelting equipment: Ross M. & M. Co., Silverton, Colo. 12 mounted slag cars, one combination trap-spout for smelter; S. S. Fowler, Nelson, B. C., Simplex table; St. Joe Lead Co., Bonne Terre, Missouri, four pneumatic ore gates; Boise Gas Light Co., Boise, Idaho, three impact screens; American Smelters Securities Co., laboratory crushing rolls for Matehuala, La Paz, Mexico; Federal Mining & Smelting Co., Wallace, Idaho, set of 27 by 14 in. Humphrey rolls; five dome-top, ball-bearing turntables for Japan; Arizona-Mexican Mining & Smelting Co., Needles, California, one three compartment set jigs.

EDITORIAL.

THE NINETY-FIRST MEETING of the American Institute of Mining Engineers is to be held at London, beginning on July 23. An attractive program has been announced by the Secretary, Dr. R. W. Raymond, and it appears likely that a number of American engineers will take the opportunity of visiting English mines and metallurgical establishments.

THE FRIENDS of subscribers in San Francisco will confer a favor on them, and on us, by telling them to forward their new addresses to our mailing department. Owing to the postal regulations, undelivered second-class matter is held for forwarding postage; and although we have written to each subscriber, it is likely that many of them will not get our notification at this time.

OUR OFFICES at New York, Chicago, and Denver have been improved so that our representatives at these centers are now in a position to welcome visiting professional men. We shall be glad if our friends will make themselves known to our representatives—all of whom acted with exemplary spirit during the brief time of confusion caused by the destruction of our central office. We take this opportunity of stating that the Boston agency has been transferred to our New York manager.

IN OUR LAST issue we referred to the fact that one of the great miners, George Lansell, had passed across that range from which no prospector ever returns. Through the 'Bendigo Advertiser,' we learn that in his will he bequeathed a gift of mine shares, in terms of money according to the current market quotation, to each of his managers and also to every miner, laborer and boy employed on his own properties. He also left $50 to every one of the pioneers who were with him at Bendigo in 1857; of these there are 90 that survive. These remembrances are characteristic of the kindly heart of the Bendigo "Quartz King," as he was fondly called throughout Australia.

THE DAILY PRESS states that the wife of ex-Governor James Budd has foretold another catastrophe and it is claimed that she predicted the recent disturbance. Such statements after the event are not uncommon; so many people foretell things and they foretell so many different things that like the shot from a "scatter gun" something is sure to be hit. It appears that despite her belief in an impending cataclysm, the lady in question bought a $1500 piano two days before April 18. We are informed that the lady possesses a private observatory, for she uses a strong glass whereby she "keeps tab on the peculiar antics of several stars" that have stayed up late and otherwise misbehaved. As to the "strong glass,"—that is a fruitful stimulant to soothsaying; but we want to know whether it was Scotch or Bourbon.

THE DAYS OF SOOTHSAYERS are evidently numbered; the time was when prophesies of disaster, especially such as emanated from elderly ladies, were calculated to create a panic. There was Mother Shipton who scared the ignorant in the year 1881 and now there is this Mrs. Budd in California who has predicted fearful things. All the daily papers quote her, so it must necessarily be true. But the spread of an elementary knowledge of natural phenomena has given men the chance to think intelligently on these matters and no foolish talk will now distress the general run of people as it used to do twenty-five years ago. The good sense and the recovery from disaster so noteworthy in our midst during the past four weeks, are to be credited to the spread of scientific knowledge—enough of it at least to give mental balance even when the earth reels and the skies seem afire.

IN A RECENT ISSUE we referred to the fact that, as far as known, no mine in California has suffered injury underground from the earthquake. It appears that this holds true of the oil-wells although the casings of deep artesian water-wells in the Santa Clara valley suffered fracture. There were a few breaks in the pipe-lines of the Coalinga district, but these were quickly repaired and entailed only slight loss of oil. There were minor breaks also between Coalinga and Monterey, and near Salinas, but there was no damage to the wells themselves. The oil production of the State is about 20,000,000 barrels per annum, worth about $6,000,000 at the wells and costing the consumer a dollar per barrel. As this product of the State has proved an important factor in lessening the cost of fuel necessary for generating power in our manufacturing industries, the preservation of the oil-wells and pipe-lines is gratifying news.

JUSTICE is proverbially slow, and in none of her departments is she so leisurely as in the meting of punishment to dishonest mine promoters. Therefore it is satisfactory to chronicle the consignment of G. W. Rumble to the jail at San Quentin. He is to remain there for a year and a half, having been convicted of fraud in connection with the Sunset Mining Company. To the postal authorities is due the credit for this conviction and while the misuse of the mails is difficult to prove, it appears that prosecution by the Government is at present the only effective check on fraudulent mining schemes. In connection with this episode, it is interesting to note in one of our daily papers the statement that Rumble went to Washington last week "to the great wor riment of his bondsmen, for the purpose of inducing the President to intercede in his behalf." A man possessed of such unlimited impudence might well occupy himself with the sale of worthless mines, for if ever there was a man who would be likely adequately to condemn such mean methods and pitiful knavery, it is the Chief Executive of the United States.

IN REGARD TO the misuse of dynamite during the conflagration in San Francisco and the blasting operations afterward, we have received several letters endorsing the criticism appearing in these columns two weeks ago. Mr. Frank A. Leach, the superintendent of the Mint, informs us that he offered to supply the services of experienced men, but the individuals doing the blasting claimed that they understood the use of explosives in demolishing buildings better than any miners. Mr. Leach now possesses a piece of iron weighing a quarter of a pound that landed in the court of the Mint when a blast was fired in the Phelan building several blocks away. Other similar pleasant projectiles were hurled to the same spot from other blasts far away. In contrast to the foolish doings of the amateur miners, we quote an instance of the intelligent—and therefore safe—use of explosives in removing masonry. When electric power was installed at the Mint in place of steam and the 150-horsepower engine, which was placed on the main floor of the building, was removed, the huge foundation of brick-work laid in cement, which filled the space in the basement underneath, was useless, and, room being needed, the superintendent concluded to remove it. It was a solid mass about 30 feet

long, nearly 20 feet wide, and 12 feet high. Mr. Leach put some men at work with picks, gads and hammers, but they made so little headway that it began to appear a hopeless task, when one of the Mint employees, Andrew Cuneo, came along and said that if Mr. Leach would allow him to use dynamite he could guarantee to tear the foundation down in good time. He was asked if he was sure he would not damage the building. He replied by saying that he would not only not damage the building, but would not break a pane of glass of the three windows situated not more than six feet away. He was allowed to proceed with the undertaking, and fulfilled all his assertions. This story confirms what we have said, that dynamite is a safe and wonderfully effective agency in experienced hands, and it needs no further remark from us to emphasize the inefficiency and danger of powerful explosives when employed by the inexperienced.

California's Opportunity.

The destruction of San Francisco is a calamity of such magnitude that few realize the problems which reconstruction involves. Fully seven square miles of the best and most substantially built portion of the city is destroyed. Here and there stand buildings practically uninjured—constructed of steel, brick, and stone,—but by far the greater portion of this area, say about 95%, is a vast ruin marked by foundations, fragments of walls, and tottering chimneys, with occasionally a tangled mass of steel, iron and earthy structural material. It has been determined, once and for all, which material best resists the terrific heat of a general conflagration. Granite structures, or such portions of buildings as were built of granite, spawled or crumbled under the blast, until the stone looks now as if it had been subjected to the action of weathering influences for centuries. Square blocks of granite were reduced to rounded boulder-like forms, their outer portions crumbling to coarse sand. Marble pillars were quickly converted into caustic lime. Even sandstone ordinarily well suited to withstand fire, cracked and crumbled before the fiery blast. Steel and iron were warped or bent, and in some instances they were even melted. Nothing resisted the intense heat but good brick. This is no new experience. Chicago, Boston, Baltimore and other cities that have been devastated by fire, all have proved that nothing better withstands the advance of a conflagration than a solid dead wall of red brick. There were many substantial buildings of steel, brick, stone and tiling in the burned district; they were supposed to be fireproof, but in several instances these were scattered singly among blocks of frame structures the burning of which created a heat so fierce that even those materials ordinarily considered noncombustible, and proof against fire, went down before it, as though charged into a blast furnace.

What of the future? Without the slightest hesitation, the men of San Francisco have decided that the city shall be rebuilt; and it will be, as fast as the material can be supplied. The city must be made safe not only against earthquake shock, but against the possibility of another great fire. It has been shown that a proper regard for solidity of construction in both foundations and superstructure, with the employment of good materials and honest work, will withstand the effect of earthquakes even of a severity as great as that of April 18. Little damage was done to the Federal buildings in San Francisco, for these were honestly constructed of first-class material, while more showy but less substantial structures were severely damaged. The walls of one building, for example, on Haight and Webster streets, though solidly built of stone, prove to be little better than a pile of loosely cemented rubble, neatly pointed on the outside. Large portions of such so-called stone walls were destroyed. The Palace Hotel, though not strictly modern, was solidly built of brick with many interior walls and partitions. The damage to this building was due almost wholly to fire, proving that brick structures, even with much less steel than is used in modern buildings, are practically proof against earthquakes, but not against the effect of acres of fiercely flaming wooden structures amid which they may be situated.

San Francisco must be rebuilt substantially. The proper materials for construction are steel, iron, brick and stone. Upon these points all are agreed, but the most serious problem is to secure sufficient material to carry on the work promptly. There is no lack of energy and determination to rebuild, and there will be no shortage of money for the purpose; but whence can the materials be obtained with reasonable promptitude?

Naturally the East is expected to supply the steel and iron; California alone is able to provide much, if not all, of the brick, terra-cotta, and stone; while California, Oregon and Washington will furnish the lumber. Lumber is the most readily obtainable, and this fact may again lead to the use of too large an amount of inflammable stuff. Much of the brick from the destroyed buildings can be cleaned and used again; indeed, this must be done from necessity, for otherwise it would take too long to make the quantity required; as it is, the brick-yards and terra-cotta works of California and neighboring States will have to run at their fullest capacity for years to supply the demand from San Francisco alone.

The most serious problem is how to secure the necessary steel and iron as fast as wanted. Every mill in the East that makes structural shapes is said to be from one to two years behind on its orders. Even before the fire it was difficult to get steel fast enough to continue steadily the construction of large buildings. Here is the real obstacle. Reconstruction cannot proceed without steel and iron in large quantities. If the East cannot supply what is required, the remedy is plain. The necessary structural steel must be made on the Pacific coast. It is well known that large deposits of iron ore are available. Heretofore it has been argued that the time had not arrived when local iron furnaces and rolling mills could compete successfully with those in the East. The present situation upsets such an argument. The iron mines of California, Oregon, Washington, Alaska, Utah and Mexico can supply the ore; a great and permanent industry may now safely be established here. Several methods of producing iron are available; the ordinary blast-furnace practice of the East; the making of blooms in reverberatories, oil being employed as fuel; furthermore, the advocates of the electric furnace have a grand opportunity, and the same may be said of the enthusiasts who have written so much about the value of the iron sand of this Coast as raw material for the manufacture of iron. Now is the time to prove it! Heretofore the main drawback to the founding of a steel industry was the lack of a local market; that market has been created suddenly; a great opportunity has arrived. The iron ore is here and can be made accessible; California produces 20,000,000 barrels of crude petroleum annually; therefore a cheap fuel is available. Why should not San Francisco make her own structural steel?

By the Way.

The London 'Spectator,' the paper rendered illustrious by Addison and Steele, founded 150 years before San Francisco existed, has this to say of our misfortune: The dominant note of the news from San Francisco has been one of unconquerable optimism.

The salient fact is the immediate decision to rebuild, to resume again the ordinary routine of life as soon as human effort can make it possible, upon the same spot, under the same skies, on the very foundations even which lie with their superstructures in dust above them. Is it reasoned decision, or mere impulse, which underlies that sudden determination? If there is reasoning, it would seem to be that what has only happened once will not happen again. The earthquake of 1868, in the words of one of the sufferers, "was nothing more than the rocking of a child's cradle," as compared with the earthquake of 1906. "There is no record of a great city having been twice destroyed by convulsion or eruption; the earth will not heave again, or, if it does, it will be at a time so distant that the contingency need not be considered." And so the plans go forward. If all the arguments are pressed home, the outstanding conclusion must be the essential sanity of the decision which determines upon reconstruction in the face of all hazards. For what are the alternatives? in which direction is safety to be sought? Away from the latitudes in which earthquakes tear down cities? But can those latitudes be limited? For, remember, the knowledge possessed by man of the causes of earthquakes is, and will possibly always remain, extremely small. All that can be said to be known, that is, apparently rightly reasoned from certain premises, is that the planet on which we live has cooled down from a glowing mass of molten matter, and is still cooling; that during the lapse of unnumbered and innumerable aeons the almost cold crust has clothed itself with the power of giving and supporting life; and that of all living beings it has been ordained that man alone shall be able to understand and reason about the vast laws of his existence. He is allowed to build huge cities where he pleases, to carve the thin stone under him to pile up palaces a hundred feet high, with more than forty million feet of unknowable matter between him and his fellow palace-builder the other side of the globe. Beneath the ground he treads, it may be but one short mile away, huge forces wake and sleep, move and are still; some unseen power shifts uneasily, writhes and rolls, and the caked coating above quakes as a bog-crust might shiver over a buried bull. Under which spot of all the surface over which he may roam will the monster writhe next? He cannot tell that; he knows only that here and there, during the few hundred years of which he has record, may be found tracts of land which hitherto have not been shaken, or have been shaken only slightly. What he does not know is whether the same laws which have hitherto prevailed can be counted on to prevail for the future. And if he does not know that—if, that is, he cannot stamp his foot on a square yard of ground and say, "Here at least it is certain that the earth will never be riven," is it not just as sane to rebuild where buildings have been shattered as to build afresh where no buildings have stood?

The builder will face that risk in his own way. He may watch his houses overwhelmed by the resistless march of lava, and with easy fatalism the next day sip wine over their ruins. Or, with the alert sanity of a nation buoyant in her belief in her mission of work, he may set himself with steady energy to make better what was good before, to use his broken buildings to teach himself lessons of knitting more soundly stone and steel and wood, to set together a new city, greater, compacter, and cleaner than the old. That is the task which has been set the San Franciscans by the genius of the great nation to which they belong. It is the genius of the American nation to grasp essential points, to rise greater than calamities, as though calamities gave wings or spurs; the greater the need for decision and courage, the greater capacity emerges for bravery and action. The descendant of the colonists who faced a new world with fresh thought and untired arms, in the crash of misfortune

"Turns his keen, untroubled face
Home to the instant need of things."

With the deep sympathy that has been felt by the English-speaking race for the sufferers in the ordeal of the last ten days there is yet mixed a high pride in the recognition of the qualities of cool steadfastness, courage, and strength which have nerved those who have sustained the greatest losses, and which are admired above and beyond other great and abiding qualities by their kinsmen.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

The ankerite masses occurring in the Mother Lode region of California are auriferous in many places, but are usually low grade. A notable exception was that in the Rawhide mine, near Jamestown, Tuolumne county.

Franklinite is a zinc-bearing iron ore, which also contains manganese. Treated with hydrochloric acid, a small amount of free chlorine is evolved. Zinc-blende, when treated with hydrochloric acid evolves sulphureted hydrogen.

The copper ore of La Sal District, on the border line of Colorado and Utah, is mostly found in sandstone The Uranium ore, for which that district is noted, occurs in the same formation, but principally in fissures cutting those rocks.

One acre-foot of storage will produce a flow of 30 cu. ft. per min. for 24 hours, or 20 miner's inches. Conversely, a storage capacity of four acre-feet is needed to give a 24-hour flow of 100 cu. ft.; or for 100 miner's inches, six acre-feet.

When drilling in sandstone the drill-bit should be tapered somewhat and then flattened instead of drawn to a cutting edge. If a chisel-bit is used in drilling sandstone the bit will wear very sharp, and will frequently become fitchered.

In the moderately humid Eastern States the annual evaporation from reservoirs is from three to four feet. Accurate data for the dry States is lacking, but probably double these figures would be a minimum. Accordingly, where existing lakes are to be used for storage, it is in general better to lower the outlet than to raise the level.

As to the effect of vibration from stamps on a mill building, if the battery foundations and those of the mill structure be properly built, a brick building would be as serviceable as one of wood, and would also be less likely to take fire. Brick mills have been in use for thirty years or more in South Dakota and Colorado, and have proved satisfactory.

For stopping the joints between slates (or shingles) and chimneys, dormer windows, etc., a mixture of the keg paint with sand enough to keep it from running is very good, especially if protected by a covering of a sheet-lead strip nailed to the mortar joints of the brick work after having been bent to enter those joints, which should be scraped out to the depth of one inch and then re-filled.

The earthquake which visited the Pacific Coast on April 18 teaches many valuable lessons in planning building construction. Two things are plainly evident: First; frail stone, brick and other flimsy buildings cannot withstand the shock. Second; properly constructed buildings on massive foundations of sound materials are practically immune from shocks of earthquake even as violent as that lately experienced.

If a tunnel is to be run to open an ore deposit in depth, it should, where possible, be driven on the vein rather than through barren country rock to reach it Often the topographical situation has an important bearing on this matter, particularly with reference to the position of mills or other reduction works. Tunnels run on the vein always prospect the deposit, and there is far better chance of striking a pay-shoot in such tunnel than in one run across the formation.

The price of platinum per ounce now exceeds that of gold. It therefore behooves the placer miners who can save it, to spare no pains so to do. Placers, the streams of which head up in areas of serpentine are the ones most likely to contain it, since platinum shows a strange fondness for the highly magnesian rocks and is seldom found in other surroundings. A very common associate with it is chromite. If the nuggets have not been washed far, chromite may even still adhere to them.

Jigging is a process of concentration which has been in use for many years. Jigs are of many types and sizes, from simple, hand-operated devices of small capacity, up to large machines run by power and treating several hundred tons daily. Jigging is applicable to the treatment of ores of any kind that are subject to concentration. Jigs are particularly useful in treating rather coarse products though they are also successfully employed in the concentration of the fine material passing through the upper screen, or that resulting from re-crushing the oversize ore from the coarser screens. Seveal minerals of varying specific gravity may be separated by careful jigging, as galena, pyrite, blende and quartz. Coarse jigs can be employed to concentrate lump ore, those lumps still having gangue mineral attached being separated from the clean ore, and returned to the crushing machine for reduction to smaller size, and re-construction.

Chemically pure iron is soft, malleable and easily welded. It cannot be hardened or tempered, as these terms are understood in relation to steel. In contact with a magnet, it becomes magnetic, but loses this property when the magnet is removed. It is unfitted for castings on account of its lack of fluidity. Those properties of iron which render it valuable as a commercial product must, therefore, be primarily due to foreign substances in the iron; and the great variety of these properties is attained by changes in the amount and nature of these impurities, and by the physical treatment of the iron while it contains them.

Enrichment.—If there are oxide and carbonate copper ores at and near the surface, and the tunnel cutting the vein at a depth of 700 ft. is wholly in sulphide ore (chalcopyrite) it is possible that a zone of enriched sulphides—bornite and glance, may be found in the intermediate section. It is impossible to tell to what depth oxidation or partial alteration of an ore deposit has progressed, or what conditions may be encountered, until these have been determined by actual development. No mining region proves this more completely than that of Butte, Montana, where surprises in ore occurrence are frequent.

Paint. The principal materials used in house painting are either white lead (containing 80% lead) or oxide of zinc (zinc white) ground in raw, that is unboiled, linseed oil by a grinding mill to the consistency of a thick paste, containing 10% oil. In this condition it is sold in kegs of 25, 50 and 100 lb. For use this is thinned down by mixing in for each 10 lb. about three or four pints more of linseed oil, when it should flow readily under the brush. When, as is usual, raw oil is added, dryers must be added, otherwise it might take several weeks for the paint to harden, whereas with dryers from one to three days, according to the weather, is time enough for each coat to become hard enough to receive the next one. For a dryer, one tablespoonful of japan varnish is sufficient for 10 lb. of the keg paint. No dryer is needed if painter's boiled linseed oil is used in place of the raw oil.

Meteorites. In the 'Concentrates' of a recent issue, mention was made of the Willamette meteorite which was found near Portland, Oregon, and about which litigation arose between the finder and the owner of the land upon which it was found. The claim of the finder was based on two grounds. First the meteorite was a gift from heaven and therefore to be possessed by the discoverer. The court rejected this plea, and while admitting that it was a gift from heaven, decided that heaven gave it to the man on whose land it fell. The second claim was that, since it had been used by the Indians in some of their rites in early days, according to the testimony of survivors produced in court, and since the Indians had ceased these practices, the meteorite was in the law like a cast-off tool or implement to which any finder may lay claim, and which he may carry off, regardless of the ownership of the land. But the court decided against this plea also, and restored the meteorite to the owner of the land.

It is unsafe to estimate the value of either a quartz or placer prospect in the pan by counting the colors that may be seen without knowing what amount of material was taken in making the test and what the weight of the gold saved is. A prospector can become expert in his judgment of the gold content of either a quartz or gravel panning, but this he learns by experience which must necessarily be renewed in each new district or mine. Some gold which shows up well in the pan is light and scaly, and the panner is likely to overestimate its value. Other gold, though occurring in very small particles, may be round and heavy, running higher than one might expect on first judgment. A pan of gravel will vary considerably in weight, depending on the character of material composing it. Some gravels contain large amounts of iron ore, garnets, and other minerals which are above the average of specific gravity of ordinary rocks. Such gravel will weigh more for a given volume than that composed of slate and quartz pebbles and sand. Ordinarily a full pan of gravel will weigh about 20 to 30 lb., but miners rarely fill the pan unless the gold be coarse and heavy, owing to the liability of loss in the preliminary stages of washing. When panning to ascertain the value of gravel per cubic yard, several pans of the material should be weighed to get an average, and the estimate made in accordance with the result, or a cubic foot of the gravel may be washed, pan at a time, and the total amount of gold obtained taken as the basis for calculating the quantity of gold per yard.

Grades. Flat slopes such as a railroad grade are expressed either in feet to the mile or by percentage. Thus we may say a one per cent slope or one foot rise in 100 ft., which is equivalent to 52.8 ft. to the mile of 5,280 ft. The slope of a sluice box or a launder may be given in inches per foot. Thus the slope or grade of an apron-plate may be 1.25 or one-and-one-quarter inches per foot. The slope or grade of a launder may also be expressed as the drop or fall for the length of a 12-ft. section. Thus we may say, 3 in. in 12 ft. In these cases the rise is mentioned first. On the other hand, for steep slopes, as those of earthwork, the horizontal distance is mentioned first. Thus stated, a slope of 2 to 1 means a slope of 2 horizontal to 1 vertical. The slope or pitch of a roof again is expressed as the ratio of its rise to its span. Thus we say that a roof has a one-third pitch when its rise is one-third its span. A roof of 60 ft. span would, if of one-third pitch, have a rise of 20 ft. vertical above the eaves at its ridge. This applies to a regular roof having two slopes. For a roof having but a single slope (a shed roof) it would still mean the same rise, but the span has decreased to one-half.

Conglomerate, agglomerate and breccia are terms often confused. By 'conglomerate' is meant a mass of water-worn detritus—cobbles, pebbles and sand, coarse and fine, cemented by some mineral substance, such as calcium carbonate, iron oxide, silica or clay. 'Agglomerate' is a term applied to a quantity of cemented or partly cemented fragmental rock material and refers more particularly to lava fragments which have become consolidated at the foot of cliffs, or in streams, or scattered over large areas in the vicinity of volcanic vents.

These fragments are usually large and small, including volcanic cinder and ash. If by erosion this volcanic material becomes water worn and cemented, it then becomes conglomerate. Conglomerates form in river beds, and on sea or lake shores. 'Breccia' is the term used to designate rock which has been shattered in place, the fragments occurring in every size from minute grains to great masses, and being cemented by the infiltration of foreign mineral—calcite, silica, iron oxides and occasionally sulphide ores containing gold and silver as well as base metals. Conglomerates are frequently metal-bearing, carrying metallic gold or copper, and ores of the base metals. Many of the most valuable ore deposits known occur in brecciated zones. Almost every kind of metal mined is found in fractured rock masses of this description, including copper, gold, silver, lead and zinc.

Re-location.—When a corporation or an individual abandons a mining claim or group of claims it becomes immediately subject to re-location, but it would be most unwise for any person to re-locate such claims when they are not subject to re-location by reason of failure to do assessment work as required by law, without first securing from the proper officials of the company—the president, secretary, and board of directors, or from the individual locator—a statement in writing specifically setting forth the fact that the claims had been abandoned. The person who originally located the claims would have no precedence over others in this matter unless the company or individual holding the quit-claim deed gave him the advantage of first knowledge of intended abandonment. A stockholder performing the assessment work in the interest of the company would only complicate matters. It would be better to allow the claims to become subject to re-location by failure to perform the necessary work, and for the stockholder to then locate in his own name. As to power of directors of a mining corporation to shut down the mine, disposing of tools, machinery, supplies, etc., and to transfer title of claims to another without calling a special meeting of stockholders, this would probably be determined by the constitution and by-laws of the company. This question should be referred to a corporation attorney in the State where the company is incorporated.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

MINING METHOD WANTED.

THE EDITOR:

Sir: I have a problem in practical mining to solve, and believe the expert who has charge of 'The Prospector' department can help me out. The problem may be stated as follows:

Given: A vein of low-grade ore, 50 ft. in thickness, dipping uniformly into a mountain at an angle of 23 degrees. Timber is available, but the low grade of the ore makes it desirable to avoid its use as far as possible. It is difficult to attack the vein from the surface on its strike, owing to the topography of the country. The ore deposit may be best described as a broad silicified zone of impregnation, conforming approximately to the strike and dip of the country rock—a rather coarse mica schist. The ground stands well so far as development has progressed, the hanging wall which constitutes the back of a large stope in this vein stands well without timbers. The slope angle of the hillside along which this vein outcrops is about 30 degrees, the croppings being about 500 ft. above the bottom of the canyon.

Wanted: A mining method whereby this vein can be expeditiously and safely mined without loss of ore, and at minimum expense.

The mine is situated in California, about 40 miles from the nearest railroad station, and strict economy is necessary in every branch of the business.

The method already tried has been that of driving a tunnel into the mountain in the foot-wall of the vein, which is reached about 600 ft. from the apex, on the dip of the vein, the tunnel having been extended through the vein to the hanging wall. From the hanging wall a stope has been carried backward toward the foot on that level, but this scheme is not wholly satisfactory.

NEW SUPERINTENDENT.

Acton, April 25, 1906.

The problem submitted by New Superintendent is one involving some uncertainty, an unavoidable element in every untried proposition in the business of mining. The best mining method cannot always be arbitrarily decided upon for any particular case prior to trial. Satisfactory methods are usually the result of experiment and evolution. If one method does not produce the best results, recourse is had to another, and methods long in vogue are improved from time to time. The character of the wall rocks, and of the ore itself, as to its standing qualities, are most important. By employment of the square-set system, and contemporaneous filling, almost any of the difficulties usually encountered in stoping orebodies may be overcome, but in the present case strict economy must be observed, and economy in this instance means low cost of mining and operating expense.

The long tunnel, driven nearly 1,000 ft. to reach the vein at a depth of 600 ft. on its dip, appears to have been an unnecessary expense, although it may eventually prove serviceable as a drainage outlet, and it will certainly aid ventilation.

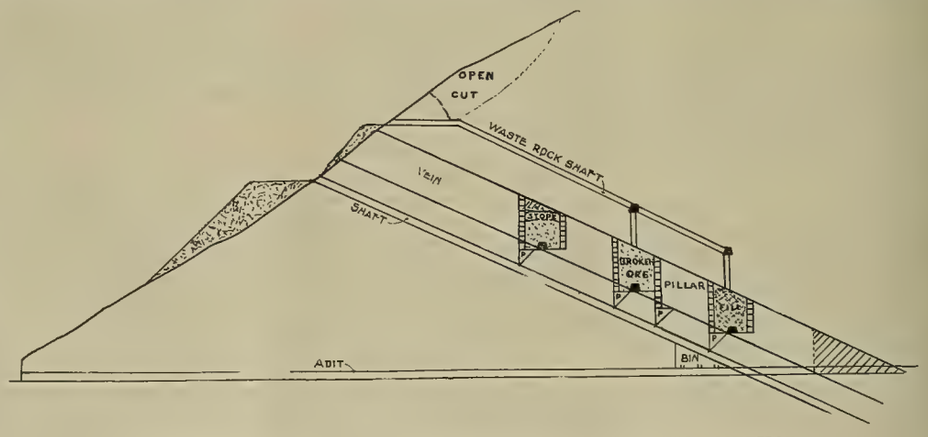
To continue to stope the vein along the lines described will certainly invite disaster. There is a limit to the extent of the superficial area to which a stope may be carried with safety. The best-standing ground has its limitations, and the removal of too large an area will inevitably result in collapse of the hanging wall country. In some instances this fact may be utilized to advantage, as where the caving system is employed, but this case does not appear to be one of them.

As viewed from a distance, and basing judgment on the statement of conditions said to exist, it is suggested that an inclined shaft be sunk from the surface in the footwall of the vein and about 30 ft. below it. This shaft should be carried down to the tunnel level, at least, and connected with it. The vein should be opened by a series of rooms, or stopes, driven longitudinally on the vein. Each stope should be 50 ft. wide, and 60 ft. would be better if the ground stands well enough to admit of it. A main gangway, heavily timbered, should be driven on the sill floor in the middle of each room, on a line normal to the shaft—extending to right and left—on both sides of it. If the ore breaks reasonably small, so that it may be handled through chutes, these should be built at stated distances, say every 30 ft., along the gangway, but if the ore breaks very large, so as to prevent handling through chutes, these had better be dispensed with, and all rock broken in the stopes shoveled into cars from the floor of the level, after the large masses are broken up by bulldozing or blockholing, by men whose particular duty it is to attend to this. The stope should then be opened up to the full width of 60 ft. and a line of square sets carried up on either side of the stope in the direction of the strike of the vein. See accompanying sketch.

The ore may be broken down in the stopes, only enough being drawn off on the sill floors to keep the miners within easy reach of the back.

These several stopes, which should be opened in alternate blocks (two stopes being separated by a 60-ft. block of ore, to be subsequently removed in the same manner as the first), must be connected with the shaft by winze for the passage of men and for ventilation. A liberal-sized ore pocket should be cut under each stope, immediately above the shaft and convenient to the gangway, into which the ore, brought by cars through the gangway, can be dumped. The floors of these stopes and blocks of ore will be arranged in a series of steps, each one nearer the surface being about 12 to 15 ft. higher than that next below.

If the hanging-wall country, when reached, is found to stand well over the entire stope, say 60 ft. wide, and of indefinite length, it may not be necessary to fill at once, but the danger will present itself when an attempt is made to stope the intermediate block—the two original stopes and the intermediate block making a total width of 180 ft., which is a dangerously large area to leave without support. It is therefore necessary to fill the stopes with waste as the ore is withdrawn before attempting to stope the intermediate block. This may be done by driving the stope some distance to either side of the shaft, allowing as much of the ore to remain in the stope as possible, thus affording support to the roof, should it begin to subside.



ILLUSTRATING CONDITIONS REQUIRING SPECIAL MINING METHOD.

When it becomes necessary to remove all of the ore, the shovelers should be placed at the end of the heading most distant from the shaft, the gangway having first been driven forward some distance beyond the face of the heading to facilitate future operations. As the ore is removed in the cars, a large open space will, in time, be left, sloping upward from the gangway floor to the back of the stope, a height of 50 ft. Filling must now be introduced, and it is an uncertain question as to where this waste rock shall be obtained, and how it may best be handled. If the hanging-wall country is sufficiently firm, inclined raises from the back of the stope may have been driven into the hanging, from which large chambers may be opened out, the rock falling into the stope beneath as fast as it is shot down. If this method is too dangerous it may be advisable to sink an incline from the surface in the hanging wall of the vein, and to break the waste there in an open cut, delivering it to the stopes by means of cars running in drifts over a series of mill holes, connecting with the stopes. Probably this latter would prove the better way.

The method of stoping here proposed is a modification of the Homestake system, differing from it chiefly in that the stopes are driven longitudinally of the vein instead of across it, from wall to wall, but the method of filling at the Homestake is very different, and far more simple, owing to the higher angle of dip and the great size of the vein.

When all of the payable ore has been removed from the surface down to the tunnel level, it might be expedient to continue the inclined shaft downward, opening out new stopes in the same manner as above, and sending the ore out through the tunnel instead of hoisting it to the surface through the incline. Also, if desirable, the ore stoped from above this adit may be lowered to that level and trammed in trains to the surface instead of being hoisted in single cars, or skips, through the incline. Liberal-sized ore bins could be provided beneath the shaft, and above the tunnel level, from which cars could be quickly and inexpensively loaded.

As the work progresses, many minor problems in detail will present themselves, each of which must be solved independently, and which cannot be anticipated at this time.

THE PROSPECTOR.

VOLCANOES AND VOLCANIC ACTION.

THE EDITOR:

Sir—Earthquakes are not necessarily the result of volcanic action, although most of those occurring near the sea-coast have this origin. Charleston was an exception; the occurrence at the Southern city represented only a slip of one stratum on another. A slip due to a thin selvage of clay between strata, or a slip along the line of an old fault, may cause an earthquake even in the midst of a continental area, and yet in no respect would the cause be volcanic. This probably applies to San Francisco.

The old ideas concerning volcanoes have been modified. Sir John Lyell was the father of the theory that volcanic outbursts were mere local phenomena. His idea was that the local seepage of sea-water into cracks leading down to the molten lava, caused volcanic emanations—such as those of Vesuvius, Etna, and Stromboli. Many modern geologists are still afraid to depart from this view. For example, Heilprin and several others who went down to Mt. Pelé, in Martinique, after the event, came back all talking of it as a local phenomenon. In regard to the recent outburst of Vesuvius even a German savant is reported as attributing the whole thing to spots on the sun!

A short time before Mt. Pelé got in action, Colima in Mexico had an eruption; then La Souffriere in the Island of St. Vincent, in the Windward group, became restless; this was followed by the outbreak of a volcano in Costa Rica; and then Mt. Pelé began. It paused awhile—and in Nicaragua a similar local and sporadic outburst started. And then Mt. Pelé became the whole show. But some of the visiting geologists reported that it was purely a local phenomenon, due to seepage of salt water on hot stones below.

Some fourteen years ago, N. S. Shaler, professor of geology at Harvard University, proposed a broader theory than that of Lyell and his friends. Being a very quiet, modest, as well as able man, his views caused no sensation, for he did not push it or orate about it. He noted that:

1. All active volcanoes in the world today are either on the coast, in case of continental areas, or on islands in the sea. Etna, Vesuvius, Stromboli, Hecla, Fujiyama, Chimborazo, and Krakatoa sufficiently illustrate this point. Extinct volcanoes now in the midst of continental areas, once were on the sea-coast. But they have been silent ever since.

2. Certain rocks are known as sedimentary rocks, such as sandstone, limestone, and slate. Originally deposited in the deep sea, in the form of sediments of sand, lime, or clay, they were compacted by pressure and afterward uplifted to the light of day. Many of these have been later subjected to metamorphic action obscuring their sedimentary origin, but the majority of them still remain as unmetamorphosed sedimentary rocks.

3. The seas are still depositing sediment, just as they did in primordial time. In one place the sedi-

ments are still sand; in another place, lime; in another, clay. The rate of sedimentation has long been studied carefully in the various seas and zones, and we still recognize that these loose sediments of sand, lime or clay, being deposited today, may become sandstone, limestone or slate at a future date. As naturally would be supposed, the rate of sedimentation in the warm waters of the tropics has been found greater than in the colder seas of the north.

4. Any given sediment falling to the bottom of the sea carries down with it a great excess of water, that remains with it.

5. Given a bed of sediment deposited from the sea, full to excess of water; another weight of sediment falls upon it—and another—and still many others. As this weight of subsequent deposits begins to accumulate above the lower sediment, at least two things must eventually happen to that sediment underneath. The first is a continually increasing compression, as the result of the accumulating weight above. As this compression continues, the semi-fluid sand or lime or clay sediment becomes more and more compact. And its final state may be rock. But pressure usually produces heat; and as the pressure on this lower stratum increases by continuous loading above, the heat will increase in proportion.

6. But no matter what the pressure may be from above, the excess of water carried down by the original sediment still remains in it. But without doubt as the increasing pressure produces increasing temperature, it must be the excess of water in the original sediment that proves itself most sensitive to the increasing temperature.

7. And still other sediments add their weight from above. And still the temperature of the included water in the lower strata increases. The boiling point is reached—and eventually higher temperatures. But still this highly heated included water is not strong enough to break out and free itself from the enormous mass and weight keeping it in place and intact.

8. But may not a time arrive, when the pressure above has created such enormous temperatures and powers of expansion in the water included in the lowest strata of sediment, that finally, with the strength of a giant, it does break out, with a temperature far surpassing that of the Siemens-Martin furnace?

9. It breaks out along the line of least resistance; that is, the line of original sedimentation. And that line of least resistance leads it toward the nearest shore—whether of island or continent.

10. And as this fearfully superheated steam rushes along the line of least resistance seeking a vent, it melts the rock along its path, and carries it along. And when at last the vent is reached, it hurls the melted rock out, and even blows it into fine dust, to be carried away by the winds.

11. But its rush is so tremendous that earthquakes, due to this intense volcanic energy, do form one of the side phenomena.

12. What does the volcanic smoke mainly consist of? Steam.

13. What was the real history of Mt. Pele? The whole Carribean area was involved, from Mexico and Central America to the West Indies—a distance of more than 2,000 miles. More than that, at that very time Vesuvius and Etna—3,500 miles away—became restless.

14. What is the history of the recent eruption of Mount Vesuvius? Undoubtedly it represents a state of stress and strain in lower sediments of the whole Atlantic area, and it would be no surprise, to learn of a volcanic outbreak at some other point in that area, the Canaries, Teneriffe, the West Indies, or Central America. For it will occur unless perfect equilibrium has been restored by the outbreak of Vesuvius.

15. What may have caused the outbreak at San Francisco? Stress and strain in the lower sediments of the Pacific area. Without doubt the seismic impulse came from the Pacific. As yet we have no certain news of the exact locality from which the impulse came that destroyed San Francisco. It may have been from the Hawaiian Islands, or from islands of the sea not connected by cable, or from those of the Dutch India Archipelago. We shall know later.

N. S. Shaler, professor of geology at Harvard University, to whom this brilliant and seemingly competent theory is due, died two weeks since and was buried at Cambridge, Mass. I have been familiar with this theory for at least fourteen years, and the above notes have been written off-hand.

A MINING ENGINEER.

New York, April 24, 1906.

The Recovery of Copper From Mine Drainage

Written for the MINING AND SCIENTIFIC PRESS by PHILIP ARGALL.

The precipitation of copper from mine drainage is of comparatively recent introduction in the West, while in Europe it has been established as a profitable industry for at least 200 years. When and where the process of precipitating (on iron) the copper in mine drainage was first turned to practical account is difficult to determine. The phenomenon of cementation is mentioned by Agricola, who wrote in 1546. The process is said to have been in operation near Rio Tinto, Spain, in 1661. Dr. Edward Brown, in the Philosophical Transactions for the year 1670, describes the process of copper precipitation as practiced at the Ziment Springs, Herrengrund, while at Agorda in the Venetian Alps it was said to have been introduced in 1692. As far as I can find out, the first practical application in the British Isles of the process of precipitating the copper from mine drainage upon iron scrap, occurred at the Cronebane mines, in Wicklow county, Ireland, about the year 1750. Dr. Henry Kenroy, writing in the Philosophical Transactions for 1751, states that the process was discovered by reason of some workmen at the Cronebane mine having left a shovel in the mine water, which was found when taken out to be turned into copper. Whereupon Mr. Matthew Johnston, one of the proprietors of the mine, turned the discovery to account, in the following process, which is compiled from Dr. Kenroy's paper, previously cited.

The drainage of the mines was run into a chain of oblong pits, each ten feet long, four feet wide and eight deep, the bottoms of which were laid with smooth flagstones and the sides built up with stone and lime, with rude wooden beams across the pits to lay the iron bars upon. The copper replaced the iron, which passed off in solution; to hasten this reaction, the iron bars were frequently taken up and the copper rubbed off into the pit; in about twelve months the whole bar was dissolved if the iron was soft but hard iron or steel was acted on less quickly and therefore was found not to answer so well. When the iron was dissolved, the water was turned off the pit and the copper shoveled out; this red copper mud was laid in heaps and when dry became reddish dust. One ton of iron produced 1 ton 19½ cwt. of this precipitate, each ton of which produced 16 cwt. pure copper; that is to say one ton of iron was sufficient to produce 1 ton 11½ cwt. copper which was worth £10 more per ton than the copper smelted from the ore.

It was subsequently found advantageous to run the drainage into settling pits, and to pass only the clear water over the irons. Evidently only a small quantity of the copper in solution was saved, as it appeared that the pits might be continued as far as the workers pleased; for the waters did not sensibly abate in quality by being subjected to the process. The quantity of copper running waste about this time must have been enormous as in one stream, 'the Sulphur brook', it was calculated to be 129,600 grains per minute, or 124,100 lb. per annum.

Dr. Pryce, in his Mineralogia Cornubiesis, published in 1778, page 291, gives credit for the introduction of copper precipitation at Cronebane to some Cornish miners who, having emigrated from Chacewater, settled at Cronebane; he adds, "Captain Thomas Butler, who was one of Redruth, and manager of that mine (Cronebane), persuaded the proprietors to adopt the scheme of precipitating copper." It is also related that the precipitation of copper on iron was noticed at the Chacewater mine, Redruth, Cromwell, in 1728; but I believe no practical use was made of the discovery till 1854. That a person named Butler was once at Cronebane is probably true, as there is a shaft on the property known as the Madam Butler. This, however, shows a leaning toward Irish gallantry; I do not recall that Cornishmen name shafts after their wives, and the name Butler is surely Irish. Then, as Dr. Kenroy wrote of what he had seen in 1751 and Dr. Pryce of what tradition had handed down to him, 27 years later, I am inclined to support the former and award to the Irish the first profitable application of the copper precipitation process in the British Isles. Furthermore the precipitation of copper from Cronebane mine drainage was an industry of considerable magnitude 150 years ago, the production of copper precipitates from 1753 to 1765 amounting to no less than $82,280; quite a respectable output considering the small amount of development on the veins, the appliances used in precipitation and the recent introduction of a mysterious and little understood process.

The pumping of acid waters in many Western mines is yet a matter of much experiment and considerable expense, on account of the corrosion of the pipes, plungers, etc. Many experiments have been made, with lead-lined pipes, special bronzes and subtle chemical compounds, in attempts to re-solve a problem that our forebears had satisfactorily elucidated before the foundations of modern chemistry were laid. Probably the first form of pump-column was the bored out and hooped log. These I have myself seen in the old workings of the Cronebane mine, abandoned before the time of the oldest miner thirty years ago, showing they are probably considerably over a century, and perhaps two centuries, old.

With the introduction of cast-iron pipes, it was but a short step forward to line them with wood, known at that time by previous experience, to be practically unaffected by the cuprous waters; nay more, it was found that the wood-lined pipe accumulated a deposit of ferric oxide which adhered tenaciously to the wood, and if not scraped off periodically it would in time choke the pipes.

I remember when a schoolboy seeing very acidulous water pumped from the Wicklow copper mines by means of Cornish pumps, the cast-iron water-columns of which were lined with quarter-inch soft-wood staves, the flange-joints of the pipes were made with gaskets composed of an iron ring 1½ by ¼ in., around which was wrapped a thickness of two inches of coarse flannel soaked in tar. In screwing up the pipe-joints this tarred flannel was pressed out over the wood lining, securely sealing the iron pipe from the acid waters, as well as making a tight joint between the pipes. Coarse tarred flannel was also wrapped around the pipes where exposed to falling water, and it was well painted with warm tar. The suction pipes for these pumps were made from logs of beech wood, bored out to size and the bottom drilled with suitable holes to form the straining orifice for the pump; the plungers and glands were made of bronze, the valves of copper and leather, but these metals corroded and were about the only parts of the pumps that required frequent attention and occasional renewal. I might add that in a wide and somewhat varied practice extending over thirty years I have never seen a case where the foregoing appliances would not satisfactorily handle the drainage of copper mines, no matter how corrosive.

The nature of the reaction between metallic iron and copper solution was of course not understood in 1751, twenty-three years before Priestley discovered oxygen; a quarter of a century before Lavoisier elucidated the theory of combustion and 53 years prior to the announcement of the atomic theory by Dalton. Therefore in the limited precipitation works existing at the time when Dr. Kenroy wrote, the operators might well be excused for considering the transmutation of iron into copper a continuous and unending reaction, for so far as their works extended "the water did not sensibly abate in quality by being subjected to the process." The mine drainage was evidently very rich in those early days; however, 47 years later (1798), the copper value of the Cronebane mine drainage had fallen off materially and we find the poor pyrites ore was heap-roasted and subsequently leached to enrich the copper salts in the drainage of the mines. As the active working of the mine fell off, the copper carried in solution gradually disappeared. I helped to re-open the Cronebane mine in 1874, at which time the effluent water carried but a slight trace of copper, though the mine had not been closed over twenty years. The drainage adits were, however, filled with ocher almost to the roof and the above-water stopes and vein exposures were almost completely sealed with ocherous deposits.

The Connorree mine, adjoining Cronebane to the east, was credited prior to 1872 with $75,000 worth of copper precipitate per annum, and was worked for a year or two almost entirely for the cement copper obtained from the mine drainage. This be it remembered, with coal at a high figure and all the water pumped from a depth of 90 fathoms. The mine closed down in 1880 and has not since been opened, but a published analysis of the stagnant mine-water taken in 1884, showed, it is claimed, 40 grains of copper to the gallon,—an excessive amount. The process of kernel roasting was carried out on the low-grade copper ores of the Connorree mine in the late sixties, and the oxidized envelopes of the sulphide kernels were leached in the mine-water, to remove the soluble sulphates, and enrich the waters on their way to the precipitation plant.

The Ballygahan mine on the same lode series, but west of the Avoca river, was not much of a copper mine, but a precipitation plant was added near the close of its active career, continued in daily profitable operation for five or six years after active mining had ended. The pumps, however, were operated by water power. Mr. G. A. Kinahan made the following analysis

of Ballygahan mine waters about two years after the close of active mining: (The returns are in parts per 100,000.)

	Before Precipitation	After
Ferrous oxide	81.81	94.75
Ferric oxide	4.30	6.70
Cupric oxide	9.32	1.91
Sulphuric acid	634.26	642.34
Manganese oxide	2.30	2.50
Zinc oxide	1.20	1.80

Returning to the Cronebane mine, the re-opening of which, after twenty years' idleness, I have previously referred to; it was found that as the stopes, drifts and working faces were cleaned, oxidation again proceeded; and the effluent waters of the mine became rich in copper. The portal of the principal adit, however, was well within the boundary of the adjoining property, the owners of which made big profits from the enriched drainage of the Cronebane mine. After repeated demands for a share of the profits derived from the precipitation works, which met with as many refusals, I was instructed by the manager of the Cronebane mine—whose assistant I then was—to proceed with the underground precipitation plant that we had worked out. The plant was a great success, as owing to the higher temperature of the water, its freedom from sediment and almost entire absence of ocher, we secured excellent precipitation. Our selfish neighbors were, however, almost driven out of business, as owing to the oxidation of the ferrous salts traveling through 2500 ft. of adit, the water carried much suspended hydrated ferric oxide on reaching the surface, and the precipitation plant of our neighbors acted mainly as catch pits for the ocher.

Immediately below the gossan of the Cronebane vein a rather soft clay filling occurred, carrying abundance of granular pyrite and various copper minerals, including sulphate; the leaching of these deposits in place by first opening them up with numerous small drifts and then turning down water through the loose gossan, soon formed a prominent portion of our mining work. These copper-bearing solutions were collected on the various levels between the outcrop and the lower adit, turned down through certain old stopes and fillings and were finally collected at the lower adit, the copper being precipitated from solution on pig iron. As we had no pay-ore on this adit at that time, our mining operations there consisted in lowering pig iron through the shafts, hoisting cement copper and attending to the underground precipitation plant.

As experience was gained in leaching copper ore in place, the following working cycle was evolved: (A) A period for oxidation; (B) A period for solution and (C) A period for the removal of the ferric oxide which had a tendency to seal up the sulphides and prevent further oxidation. The first two periods were obtained by dividing the ground into sections, some of which were oxidizing while others were leaching. The C period was obtained by running short drifts across the vein and allowing them to cave; stoping was in some cases resorted to, simply to give room for the settling of the vein matter,—while in bad cases the vein-matter in places was caved through to the gossan workings, and the material used to fill stopes below, in which the caved material was in due time again subjected to a leaching process. The method was entirely successful, but after my retirement it fell into disuse and the mine was eventually closed down.

I visited this property in the summer of 1901 after twenty-two years' absence, during twenty years of which the mine was idle. I found that the precipitation of copper from the mine drainage had long since been abandoned, because there was but little copper in the water, and that little could not be precipitated on account of the great quantity of ocher present. The ocher industry was, however, flourishing, large settling ponds having been constructed at the mouths of the adits, to collect this pigment, which commanded a ready sale. Some men were gophering through the softer and yellowish gossan on the back of the lode, in search of ocher of sufficient purity for pigment. One party had penetrated the gossan and reached the soft granular pyrites previously described; their picks and shovels, coated with metallic copper, excited no attention from the descendants of a keen and intelligent race of miners.

Here the shovel episode of 1750 is repeated, a century and a half later, in a slightly different manner. The copper sulphate in the moist pyritic sand and clay underlying the gossan attacked the iron of the tools, plating them with copper. The mining spirit and even tradition had, however, taken their departure, and the husbandman gophering between seedtime and harvest in the surface workings of a great vein, failed to realize the importance of the treasure that not only surrounded him, but actually plated the instruments of his toil.

The Southeastern Illinois Oil Field.

Written for the MINING AND SCIENTIFIC PRESS by H. FOSTER BAIN.

While oil has been obtained for a number of years in Illinois, the quantity has always been small. In the last year a new field of considerable importance has been developed in Clarke, Crawford, Coles and Cumberland counties, south and west of Terre Haute, Indiana. This field has been producing since last June and now is shipping 60,000 bbl. per month. Only a portion of it is yet reached by pipe-lines and a large increase in production within the year is expected. The oil lies mainly at shallow depths, 300 to 400 ft. and therefore is apt to be pumped out rather quickly. In the southern part of the field where the wells are as much as 900 ft. deep, a longer life, though not necessarily a greater total production, may be predicted.

The oil occurs in sandstone and porous limestone about at the base of the coal measures. The principal localizing factor seems to be a low, rather flat, anticline, which, not improbably, marks the southeastern extension of the well-known La Salle anticline. The field, while near that of Terre Haute, is not related to it, but belongs probably with that at Princeton, Indiana, where oil has been pumped for several years.

The area is now being investigated for the Illinois Geological Survey by W. S. Blatchley, who has been assisted by A. W. Lewis. The following analyses, made for the Survey by F. F. Grout, indicate sufficiently the grade of the oil.

Crude Petroleum No. 1 Briscoe Lease. Original oil had sp. gr. 0.887. Flashed and burned at 60° C. 500 c.c. used for distillation. The heat was raised slowly until the first drop fell from condenser, and then regulated so as to distill at a regular rate of about two drops per second. First drop came at 88° C.

Distillate	Volume per cent	Sp. gr. at 15.5° C.	Beaume degrees	Flashed Centigrade degrees	Burned Centigrade degrees
Up to 150° C	4.4	0.745	58		5
150 to 200	11.0	0.773	51	15	25
200 to 250	9.1	0.813	42	58	60
250 to 300	13.1	0.844	36	70	95
300 to 350	50.0	0.863	32	45	76
Coke (and loss)	12.4	—	—	—	—

First three distillates colorless with slight opalescence. Color began to distill at 290°. Bloom or fluorescence began to be noticeable about that time. All fractions darkened in 24 hours. First two distillates had good, sweet, oily odor. Next two were very strong with H_2S, after standing a short time. Last fraction had also a slight odor, and was brownish red to green fluorescent. The oil seemed to 'crack' readily and completely to coke and an oil was distilled at about 325° C. If the process was stopped before complete, the residuum was a black pitch of various degrees of hardness depending on the degree of distillation. When 80% of the oil (by volume) had been distilled, the fraction above 300° had a specific gravity of 0.860 and flashed at 47° C. The residuum was a little too soft and sticky to be chewed in the mouth. About 3% more left a good firm asphalt-like residuum; 4% more left coke. The last 7% of oil to be distilled had a specific gravity of 0.878 and flashed at 43°. Cold test was 10° C. The low-flash test of the fifth fraction is further proof of the 'cracking'; 100 c.c. of this was re-distilled in part to see if the flash could be improved. After 15% was distilled, the remainder flashed at 150° C. Sulphur in original oil equals 0.23 per cent.

Crude Petroleum No. 2, Bayliss & Haskel Lease. Original oil had sp. gr. 0.873. Flashed and burned at 38° C. Tested as No. 1 was, and was very similar, a little lighter. First drop came at 53° C.

Distillate	Volume per cent	Sp. gr. at 15.5° C.	Beaume degrees	Flashed Centigrade degrees	Burned Centigrade degrees
Up to 150° C	8.6	0.741	59		5
150 to 200	10.6	0.778	50	12	20
200 to 250	10.7	0.814	42	50	60
250 to 300	13.5	0.841	36	74	107
300 to 350	48 0	0.853	34	37	45
Coke (and loss)	8.6	—	—	—	—

Same kind of distillates as came from No. 1. When 84% (by volume) was distilled, the residuum was soft and sticky at ordinary temperatures. When 87% was removed it was hard and could be chewed in the mouth. These asphalt-like residues were quite odorless and nearly tasteless. The flash test of the fifth distillate could be raised as before, by distilling off about 15% of the lighter oils which evidently resulted from 'cracking' during the first distillation. Sulphur in the original oil equals 0.73 per cent.

Crude Petroleum No. 3, Rivet's Well. Original oil had sp. gr. 0.870. Flashed at 43° C. Burned at 60° C. Much like No. 1 and 2. First drop came at 60° C.

The oil crackled and sputtered about 90° C. and when the first distillate was examined it was found to be in two layers. Probably a little water caused the trouble. The lower layer amounted to about 0.5% of the original oil. There was no odor of H_2S—neither during the distillation nor after the distillates stood 24 hours in a closed flask, 0.10% sulphur was found in the original oil.

Distillate	Volume per cent	Sp. gr. at 15.5° C.	Beaume degrees	Flashed Centigrade degrees	Burned Centigrade degrees
Up to 150° C	3.5	0.749	57		5
150 to 200	12 0	0.775	51	—	22
200 to 250	14.2	0.809	43	52	70
250 to 300	10.6	0.837	37	80	92
300 up	50.2	0.849	35	27	45
Coke (and loss)	9.5	—	—	—	—

By way of comparison the results of an examination of the Indiana oils are quoted below. These analyses were made by W. A. Noyes. The Terre Haute oil is from the Corniferous, while the Van Buren oil was from the Trenton of Grant county.‡

	TERRE HAUTE				VAN BUREN.			
	Per cent.	Sp. gr.	Beaume Degrees	Flashing Point Centigrade	Per cent.	Sp. gr.	Beaume Degrees	Flashing Point Centigrade
Original oil		0.879	30			0.853	35	
Below 150° C					7.2	0.719		Below 20
150 to 200	12.0	0.793	48	38	10.2	0.759	56	Below 20
200 to 250	14·0	0·825	41	65	10.2	0.799	47	60
250 to 300	13.6	0.847	36.5	85	12.2	0.826	41	82
300 to 350	14.8	0.867	32.5	97	14.8	0.844	37	96
350 to 390	40.6	0.879	30	45	41.8	0.860	34	38
Total distillate	95.0				96.4			
Residue by weight	6.2 per cent.				4.5 per cent.			
Sulphur	0.72 per cent.				0.83 per cent.			

The oils were distilled rather slowly from flasks with the thermometer in the vapor only. A thermometer filled with nitrogen and graduated to 460° C. was used. The oils appear to be quite similar in general character, but there is less of the low boiling products in the Terre Haute oil, and the specific gravity of the oil and of the various distillates is higher. The portion of the Terre Haute oil boiling at 350 to 390° deposits considerable amount of solid paraffine at 15° C. The low flashing point of the high boiling oil must be due to a partial 'cracking' of the oil. From the results, I calculate the following percentage of naphtha and kerosene contained in the petroleums:

	Terre Haute	Van Buren
Naphtha below specific gravity 0.73	none	10 per ct.
Kerosene between specific gravity 0·73 and 0.83	30 per ct.	33 per ct.

Ventilation by Compressed Air.—The Associated mines, at Kalgoorlie, Western Australia, have a large air compressor, designed for 60 drills, and stated to be able, with an expenditure of 1,000 horsepower, to compress 5,000 cubic feet of free air per minute. According to the returns made by the manager, the amount of air ordinarily put into the underground workings is 1,700 cubic feet of free air per minute, which supplies 20 drills and two air winches, while about 100 cubic feet per minute are used in driving pumps. Taking the winches as using 300 cubic feet per minute, and neglecting leakages, the amount supplied to each drill would average 65 cubic feet per minute. The number of men underground is returned at 292, or, say, 100 men in one shift. The total amount of air per man put into the mine by the compressor therefore only averages 17 cubic feet per minute. Taking the men on the drills only, each drill having two men, the quantity per man averages 32½ cubic feet per minute. As each drill when actually working probably liberates over 100 cubic feet of air per minute, the average of 65 cubic feet must be much higher than the amount set free while the drill is not working, and the amount supplied to the men while setting up the machine must be very small. Usually the air is used for blowing out the smoke, and then is cut off, or almost so, while the men rig the drill. During this period the ventilation is often very deficient. Analyses made by Mr. Mann show that even when the drills are running, there are places where the ventilation is bad.

The Commissioners do not wish to be understood to mean that in the instance quoted and in similar cases the only ventilation in the mine is that from compressed air, for, as a matter of fact, the principal air supply to these mines is obtained from natural ventilation. The figures quoted were meant to show that the compressed air by itself is a quite insufficient supply, and would not alone be able to maintain the air in a pure state. Usually, there is a certain amount of air from the main airways slowly finding its way into even such places as are some distance from the main air currents, and gradually removing the vitiated air.—From Report of Royal Commission, Western Australia.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The mineral specimen from Kendall, Mont., is hematite, (iron oxide).

The rock from Tombstone, Ariz., marked A. G., is quartz. The included greenish crystals are fluorite.

The sample rock marked No. 1, from Barron, Wash., has the appearance of being a much altered hornblende-andesite. No. 2 is quartz-porphyry.

Sample No. 11, from Homestead, Ore., marked C. C. C., is an acid dike rock, considerably altered, and veined with seams of calcite. No. 12 is felsite, with pyrite. Felsite is also an intrusive rock. It is probable that No. 11 was also originally felsite.

Sample No. 1 from Chilpancingo, Guerrero, Mexico, consists of granular quartz and scales of chlorite altered from hornblende. It is a metamorphic rock. Veinlets of pyrite and quartz are arranged in nearly parallel lines extending through the rock. No. 2, is a metamorphic rock, probably Diorite, in which there is considerable quartz with a streak of Mispickel, (arsenical-iron sulphide.) No. 3, is a complex sulphide ore, in which the most abundant minerals are bornite, chalcopyrite and pyrite. Galena and zinc-blende are also present in finely disseminated grains. The ore probably contains precious metals, also.

The rocks and minerals from Oracle, Ariz., marked

THE DRILL AT WORK.

A. B. C., are determined as follows: No. 1, Calcite discolored by iron oxide; No. 2, a brecciated feldspathic dike rock with much infiltrated quartz, and disseminated iron ore; No. 3, Diorite; No. 4, Amphibolite-schist; No. 5, Quartz-diorite; No. 6, Diabase; No. 7, Marble (crystalline limestone); No. 8, Silicious iron ore; No. 9, Chrysocholla; No. 10, Malachite, (copper carbonate); No. 11 has the appearance of being feldspathic vein material, much altered and impregnated with limonite (iron oxide) and a little green copper carbonate; No. 12, Malachite; No. 13, group of quartz crystals stained dark red by iron oxide; No. 14, Malachite, (green copper carbonate), Azurite, (blue copper carbonate), and Chrysocholla, (green copper silicate); No. 15, Wulfenite, (lead molybdate); No. 16, a much decomposed Quartz-porphyry.

Consul Worman forwards from Three Rivers the report of the Canadian agent at Christiania, Norway, on two important inventions in connection with the iron and steel industry. The inventors, Mr. Grondal and Mr. Kjollen, engineers, have found new methods for producing iron from the ore. By Mr. Grondal's system the ore is crushed to fine dust, and iron is drawn out by the aid of strong magnets, after which it is moulded into brick forms. Mr. Kjollen takes for the same purpose electric power. An organized company, which owns his patents, has made contracts with French, German and Italian firms for the use of the method for a production of three million tons of steel and iron per year. Similar agreements have been made for the Grondal method with several important companies, Krupp, the cannon manufacturer, being one of them.—American Manufacturer.

Sampling With a Churn-Drill.

Written for the Mining and Scientific Press by Matt. W. Alderson.

My attention was called recently to a mining property which made a large surface showing of low-grade ore. The appearance was that of the outcrop of a blanket vein, or possibly a broken-down portion of a large lode. There were several shafts on the property, the deepest about 30 ft., which was as far as one could go with a whim because of water. To sample properly the surface showing would mean many holes, and drill-

POWER FOR THE DRILL.

holes would be the most economical and give a more perfect sample. No core-drill of any kind was available in the locality; the ore was of a kind that would not be hard to drill, and it being possible to point all the holes downward, therefore it seemed to me that the deposit might be sampled and the lay of the ore determined by the aid of a churn-drill. Acting on this view, a well-drilling outfit in operation one hundred miles away was secured and brought on the ground.

This drill was of the hollow-tool type, the cutting bit being attached to a line of pipe drill-rods, through which the drillings were brought to the surface continuously by pumping, there being a leather valve at the connection between the drill and the pipe-stem. In the operation of this drill it was possible to determine just the kind of material that was being passed through at any time. A water-box stood at one side, and in dry ground this was kept filled so that a small amount of water ran into the hole, thereby supplying both the drill and pump. Where the ground was compact, little water was needed, and when the drill reached the groundwater no more was required, the operation being continuous. Where the formation was open, the water would go out of the hole as fast as it was poured in. In this case the drill-stem filled with solid drillings; it became necessary to remove them so as to get a sample, and there was danger that this sample might

OVER THE EDGE OF THE SHAFT.

be imperfect. However, where water stood in the bottom of the hole the pump worked so perfectly that only an ounce or two of drillings was found in the stem when it was removed. The drill had a drop of ten inches. When the horses were allowed to take a lazy gait the speed was 50 drops per minute; but they had been trained to step lively and the drops averaged 70 to 75 per minute.

To catch the drillings, an ordinary five-gallon kerosene can was set in the water-box, and this was replaced by an empty one as often as it was desired to take a sample. Thus in ground we were particular about, we took a sample every foot. Any material change in the ground which was being drilled would show in the color of the water; but, if I wished, I had only to hold something under the drill-hose and catch a few of the drillings to tell exactly what kind of rock the end of the drill was in. In hard ore the drillings settled instantly to the bottom of the can, and it was only necessary to pour off the supernatant water and dry the sample. Where the material was slimy and it was thought there might be ore in the slime, I could stir the sample thoroughly and then dip out a part of it, or place all the sample in pans on top of a stove for evaporation. I found that, by bringing what was in the pans to a boil, nearly all the slime would be precipitated. The extra water being poured off, the slime was soon dried and then sampled down to such size as it was desired to send to the assayer.

On one day only was any serious difficulty experienced because of the hardness of the material encountered. On that day three feet measured our progress. The difficulty was not in drilling through the rock, but because the drill bits soon lost their gauge, so that the next bit would not follow. Being present on the ground when this trouble occurred, when it was found impossible after resorting to methods usually successful to get a newly sharpened drill to within a foot of the bottom of the hole, I let a dynamite cartridge of three sticks down to the bottom of the hole (then 21 ft. deep) by the aid of fuse. On firing this the hole was sprung so that drilling was re-

OVER A PROSPECT HOLE.

sumed without difficulty. Later on, in the same hole, I fired two other charges of one stick each, one at the bottom of the hole and one four feet above. For these holes I used shorter fuse, to save time, and lowered the charge to the point desired by strong twine.

Experienced drill-men would say that such a machine as was used in this instance was not the best for work of this character, and I am not recommending hollow-pipe or self-pumping tools for rock that would be classed as hard for hand-drilling. Rope-tools are said to be best for rock of this kind where a churn-drill can be utilized. But there are times when one cannot get just the best thing, and he shows judgment and mechanical skill who makes a machine not intended for such work do it creditably and without injury to the machine itself.

The drill and necessary horses and men to run it were hired by the day at a price considerably greater than if the job had been of any length. Nevertheless, 200 ft. of 2½-in. holes were drilled at a cost of $2.76 per foot. The actual cost of the drilling was $1.65 per foot. The cost of bringing the drill on the ground and returning it, together with cost for oversight, assaying, etc., was $1.11 per foot. Our average per day was about ten feet. A better average than this would have been made on a long job, or on a job where fewer moves and deeper holes would be required. In drilling in hard rock with a churn-drill, one needs a number of sharp drills, as it is best to change frequently before the gauge is so worn as to cause trouble in making the next bit follow.

The experiment was a success in that the work was much more expeditious than shallow holes put down by hand. In several instances the drill was set over the edge of prospect holes and shafts, and work commenced from the bottom of these. (See accompanying illustrations.) In one hole we drilled 30 ft. below water. The sampling of this 30 ft. by a shaft would have cost more than the entire cost of putting down the 200 ft. by the aid of the drill.

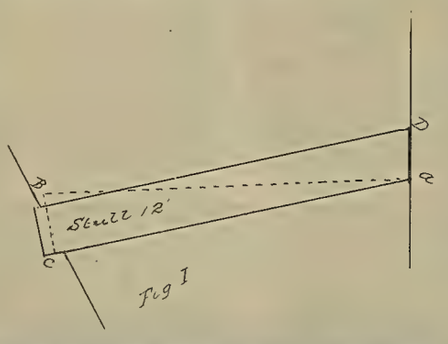
Underground Timbering.

Written for the MINING AND SCIENTIFIC PRESS by
R. B. NICKERSON.

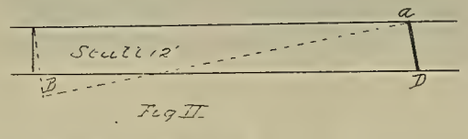
The timbering of heavy ground has been brought to such a state of perfection that, from a mechanical point of view, it can be safely asserted that any body of ore can be taken out, no matter what the conditions, or any piece of development done, no matter how difficult. The difficulties have all been overcome until now a first-class underground timberman will tackle anything and carry it through successfully and profitably too, if the pay is in the rock. Time was when rich orebodies were left or lost because the ground was too heavy to be worked. Nothing of that kind now. Long experience, modern methods and mechanical ingenuity, removed all that, and today, the right man will work anything underground. Most of those who do this kind of work are uneducated, and never learned a trade nor is it necessary that they should. What they need most is a good mechanical head, and years of underground experience. Some learned the carpenter's or millwright's trade, and this helped them, as sooner or later a timberman must learn the ways of the square and compass; but again, while learning their trade, they were missing the opportunities for observation of the tool-nipper and powder-monkey. The timberman of today has quite an array of different systems to call to his aid, and he uses the one he considers best to meet the conditions as he finds them. Here is where his experience and judgment come into play. From the simple stull, post and head-board to the elaborate square-set system, with all the different sprag and girth modifications of the same, he uses the one he thinks will best meet the requirements of safety and economy. It is constantly a question of safety versus economy underground, for if bodies of ore cannot be taken out with profit, the days of the mine are numbered; further, it is not only necessary to hold the ground and take out the ore with profit, but the cheapest system of timbering consistent with safety and good mining must be used. This is the idea of the caving system, whereby large bodies of ore are safely worked out and a minimum amount of timbers used. Timbers cost money; they represent a goodly proportion of the monthly expense account, not only the original cost of the sticks, but the expense of framing, getting them underground and through the stopes, setting up, blocking, etc. If the best system is economically used, they are a necessary expense; if not, there is a great waste. In low-grade mines, where the margin of profit is small, the expense of timbers and timbering makes a large sum total in the expense account. The careful foreman, shift-boss and timberman should, therefore, use his best judgment as to the system employed in timbering every individual stope, for in the same mine there is often a great difference in the character of the ground in the various workings. Simple stulls or post and head-board would do for one stope where a system of sets of large timbers would be necessary in another, and in another opening, while possibly requiring sets, the ground could be held by much smaller timbers, thereby effecting a saving in the size of timber used. Miners are naturally prone to extravagance in the matter of using timber. Danger is always present and they want to be on the safe side. But there is a wide scope between what is actually necessary and extravagant waste. In the matter of fore-poling, it frequently happens that two or three poles or lagging would hold the back, but it is such an easy matter to slip them in under the bridge and tail them, and the set looks so snug and neat that unless the miners are constantly watched and reprimanded, they will get into the habit of doing it, and do it right along, and this is a big leak. Good paying mines are more prone to extravagance than the ones where it is nip and tuck to meet the expense account. Miners will say, "Oh, what in hell is the use of being so damned cranky, she is paying anyhow." But I say, stop the small leaks; it is often a matter of life and death to a mine that might become a valuable property, a credit to the operators and a benefit to the country at large.

In the course of mining work, it often becomes necessary to run an old filled stope to use the waste to fill some other working stope. It is a good plan to go up in the old stope, if possible, and see how it looks, how the timbers held the ground, etc., and if the best system of timbering was used. Valuable ideas are often to be obtained in this way. It might be that above the vein of ore and the casing of gouge there was several feet of ground mistaken for the hanging wall, and lagged and timbered at great expense, while just above was the main hanging, hard and firm. Had this been known, the stuff above the vein could have been gouged out and the stope filled with it, and the rock taken out at much less expense. The point is to find this out before an expensive method of timbering is adopted.

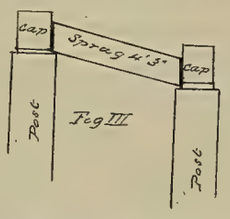
All heavy mines should be equipped with a small saw-mill plant, including a cut-off saw, a timber-framing



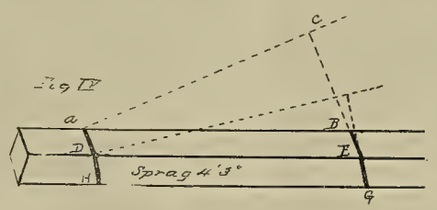
machine and a small saw for making wedges. Not only will the saw-mill cut all the lumber required on top, but the timbers can be cut to the proper size to do the



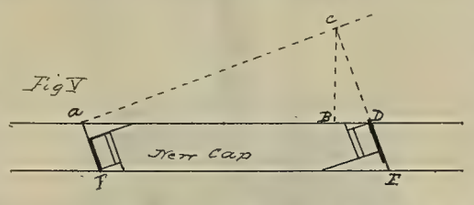
duty required of them underground, while the outside slabs can be made into poles, lagging, plank, etc., and the waste stuff made into wedges. The use of poles



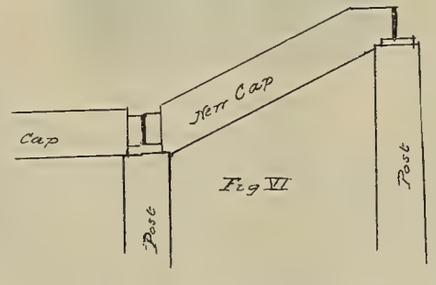
supersedes the more expensive method of shorter lagging and false sets. In using lagging in bad ground they are first worked ahead about 2½ ft. over the cap



and sides of posts. The breast is then worked out and hitches dug and a light false set put in. The false set then supports the lagging, which is again driven ahead;



the ground is then worked out and a main set put in. But frequently, after the false set is in, the lagging is driven ahead with difficulty, as the ground settles



heavily on them. In using poles, they are worked ahead full length, and well tailed; this will usually support the ground until the next set goes in. Poles are also an advantage where machines are used, as, when sets are placed 5 ft. from center to center of posts, a 5-ft. round can be drilled.

In taking the measures for timbers underground, many different methods are employed. The timbers must be framed to fit the ground and as the ground lies in every sort of shape, it is constantly necessary to take many difficult bevel measures. Some of the systems are complicated and require a thorough knowledge of angles to use them. Others are more simple. The following will illustrate one method which, while it is not claimed to be the best, is simple and accurate. Say that a stull is required with a beveled head (Fig. 1). The timberman taking the measure, first gets the length of the stull, which we will say is 12 ft.; he then places his slide-staff at a right angle to the hanging wall, A B in the diagram, and measures the distance B C, which we will say is two feet. This he calls the 'fly.' If he thought the ground required a 16-in. stick of timber his record of this measure would be:

900 Drift.

16-in. stull: 12 ft. long; 2 ft. fly.

It is a good plan when a mine requires two or more timbermen, for them to take turns at taking the measures underground, one staying on top to frame the 'rush' orders. Miners try to get their hitches dug as soon as possible, then send for the timbermen and busy themselves working out the back, putting up staging, etc., until their timbers come. If the miners were waiting for their stull, he would write the words "Hurry up" on his memorandum of the measure, sending it up on the skip to his partner, who would frame it in this way. He would roll a 16-in. stick on the skids, measure off 12 ft. on it. The line A C in Fig. 2. Taking his slide-staff, he would lay one end at the 12-ft. mark, illustrated by line A B; then take another staff and lay it at right angles to line A B, at the point B, two feet (the fly) from point C, and draw line C D across the stick, which would be the head bevel required. Suppose it is required to cut a sprag for two ordinary sprag sets, where, for some reason or other, one set is higher. This would require a bevel both head and foot as shown in Fig. 3, and the timberman's notes would read, if he needed a 10-in. stick:

10-in. sprag;

4 ft. 3 in. long; 12-in. fly, head and foot.

But suppose one set was not only a foot higher than the other, but there was an offset of a foot and a half, that is one set was 18 in. farther laterally in the wall than the other (See Fig. 4), then his notes would read: 10-in sprag; 4 ft. 3 in. long; 12-in. fly, head and foot.

Double bevel. 1½ ft. flare, head and foot.

He would use the word 'flare' instead of 'fly' in the second bevel to indicate to his partner that there was an offset in the timbers and a double bevel was necessary. His partner would understand it at a glance and could frame the stick as accurately as though he had taken the measure himself. He would frame it as seen in Fig. 5. He would take a 10-in. square stick, mark off 4 ft. 3 in., as A B in Fig. 5; place his staff at point A; measure his 1½-ft. flare at C and mark the line B E across the stick at right angles to A C. Then mark the line A F at right angle to A C. This would be his flare bevel. He would proceed the same for his fly bevel taking a foot fly from point E and marking E G and F H across the stick. He would then saw it at these marks.

Suppose that the hanging wall on a flat ledge suddenly rises and then takes its course again. It would not do to change the pitch of the post so a bevel must be put on the horns of the cap as in Fig. 6. The timberman taking the measure of this set would write the name of the stope—and, by the way, all large stopes sooner or later get a name which sticks, such as Cannon Ball stope, Powder stope, Klondike stope, Nigger Heaven, etc. So the timberman taking the measure would write:

Cannon Ball Stope;

Post, 8 ft. 10 in.; cap cocked up 3 ft.; sprag, 4 ft. 4 in.; 3 ft. fly. Hurry up.

When his partner on top gets this order, he knows that it will be longer than the regulation eight feet, so he cannot draw on the stock of caps already framed. As it is a rush order, he rolls the proper sized stick onto the skids and proceeds to find out the length of the cap as indicated by Fig. 7. He takes a staff and lays it across the stick eight feet (the regulation length cap) from end of the stick C G. Then he measures three feet on this staff from the stick C B (the height the cap is cocked up), and places another staff from C to A. He then moves his first staff C G to C E, placing C E at right angles to A C with his square. He then marks A F and D E, and saws this off—which is the length of the new cap. He proceeds to frame the horns of the new cap at right angles to A F and D E. His cap framed, he saws off his post 8 ft. 10 in. from a

stick framed ahead; champers the end, cuts his beveled sprag and the set is ready to go below. When in place, it will look like Fig. 6.

More illustrations could be given, but this is sufficient to show that any bevel can be cut by the use of this system, and two men, working to advantage, can turn out a great deal of good work—taking their regular turns to go underground—rushing their "hurry up" orders and framing caps, sprags, and the ends of timbers for posts during slack times, so as to be in readiness when the rush comes. The system has this advantage; you are working from the long end, like that gained by a peep sight on a rifle or looking through a long telescope, as a slight mistake in the 'fly' of a 12-ft. stull or a long stringer would not make any material difference in the end bevel. But a slight mistake in the angle taken of a 6-in. horn would make a bad fit for the cap. Again, the measure can be taken from the ground, which is quite an advantage when measuring a long stull; as compared to placing a ladder to take the angle of the hanging wall.

Madagascar Mining Laws.—Consul Hunt reports from Tamatave that a French decree has been promulgated announcing new gold-mining regulations for Madagascar. The changes lay stress upon the essential difference between a prospecting permit and a mining permit, but reduce the area from a radius of 2 to 1 kilometer (0.62137 mile), and impose a charge of $4.82 instead of $19.30. Mines are divided into alluvial and reef classes, taxed as follows: The 5 per cent ad valorem tax on the output is retained. In the case of alluvial mines a surface tax of $0.38 per hectare (2.471 acres) will be imposed, and for reef mines a tax of $19.30 per hectare. The Government also retains 5 per cent of the net annual profit above $48,250. On the other hand, the 5 per cent tax on the output will be reduced or altogether suspended in the case of those reef mines where the expenditure during the earlier working stages absorbs the whole of the output. Finally, the interests of holders of prospecting and mining permits are safeguarded by temporary measures which provide for progressive application of the financial regulations imposed by the new decree. The consul forwards the complete translated text of the Madagascar gold-mining laws, which can be seen at the Bureau of Manufactures.

The refining of cyanide precipitate is of some importance, owing to the well-recognized losses taking place in the ordinary methods, which are from two to six per cent. The following is a description by C. W. Merrill of the process used at the Homestake mine at Lead, South Dakota, in which the loss is less that 0.1 per cent: The precipitate, after removal from the presses, is treated first with dilute hydrochloric acid in a lead-lined mixing-tank, equipped with a mechanical agitator, a hood, and a powerful exhaust fan. After agitation and settling, the supernatant liquid is forced through a filter press by air pressure. Sulphuric acid is then added, agitation begun, and the mixture heated. It is then settled and the supernatant solution put through the press, as in the case of the hydrochloric acid. Wash-water is then added to the mixing-tank and the whole mixture put into the press, where it is further washed. The aggregate value of the acid-liquors and wash-water flowing from the press is less than $20 from $50,000 worth of precipitate. A portion of this value is recovered from a large settling-tank, into which the effluent solutions flow, and the remainder constitutes the only loss we have been able to find in this process of refining.

The resultant acid-treated precipitate is then removed to a large steam-dryer, where a part of the moisture is expelled, but never all, and the precipitate mixed with litharge, borax, silica and powdered coke. When thoroughly mixed, it is sprinkled with a solution of lead-acetate and the whole mass briquetted under a pressure of 4,000 to 6,000 lb. per sq. in. The zinc having been removed and the briquettes having been dried, a borax-slag develops upon the outer surface upon being charged to the cupel, and they fuse quietly, quickly and at a low heat, without dust or volatilization losses. The lead absorbs the values, sinking to the bottom, and slag is tapped off. All of the slag having been removed, the lead is cupelled off as litharge, and the resultant metal, 975 to 985 fine, is ready to run into bars. The cupel-slag and the cupel-bottom are then put through the blast-furnace, the lead-content of the slag reduces to lead, which absorbs the values, and is drawn from the lead-well in the usual manner. This lead is returned to the cupel at the next clean-up, the litharge from the cupellation goes to the next precipitate, and the blast-furnace slag is worth less than $5 per ton.

A Wood-Burning Assay-Furnace.

Written for the MINING AND SCIENTIFIC PRESS by EDWARD H. NUTTER.

To those engineers who are operating mines in localities where freight rates make the importation of assay fuel inadvisable, and where a fairly cheap supply of wood can be obtained, the following notes on the performance of a wood-burning assay-furnace may be of interest.

This furnace is what is known as the two-muffle tile furnace, and was furnished by the Denver Fire Clay

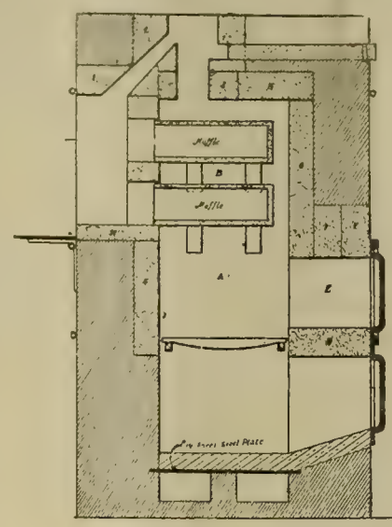


FIG. 1.

Company. Its construction can be seen from the accompanying illustrations. Instead of the fire-box and passages being lined with fire-brick, they are lined with thick tile made of fire-clay and molded to shape, which

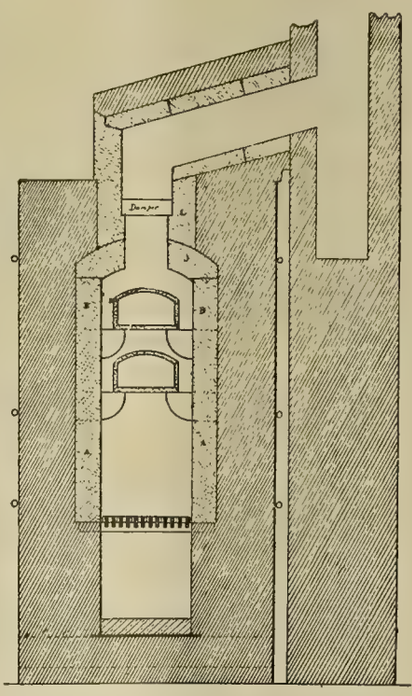

FIG. 2.

cheapens the construction. The furnace was installed in the assay office of the Standard Consolidated Mining Company, at Bodie, California, at the beginning of the present year, and has been in nearly continuous operation since then.

Prior to its installation, melting and cupellation were done in separate furnaces, using charcoal for fuel. The charcoal was made from nut-pine, and was furnished by the Chinese burners for $0.235 per bushel of 1.25 cu. ft., landed at Bodie. Last summer the Chinese who had been furnishing the charcoal decided to raise the price to $0.25 per bushel, and so it was determined to try a wood-burning furnace, for petroleum or its products to do the same work would cost a good deal more delivered at Bodie than the charcoal at the increased price. Bodie is situated in Mono county, about 100 miles from Carson City, Nevada, the railroad shipping point since Hawthorne was left off the railroad, and the wagon-haul from Carson to Bodie costs $1 per 100 lb. for all classes of freight. The furnace was ordered in August, but on account of the freight congestion due to the Tonopah-Goldfield rush, it did not reach Bodie until December, and was not erected until the middle of January.

The wood available for use in Bodie is 'bull-pine' cord-wood (a soft, punky pine, and about the poorest fuel one could find), 'bull-pine' limbs with the bark on, (which is a good deal better), and nut-pine, which is a good grade of 'pitch-pine.' On account of the uncertainty of the supply of nut-pine, it was decided to try limb wood. This, cut in two-foot lengths for the furnace, costs $6.50 per cord, delivered.

It naturally took the assayer a few trial heats to learn the characteristics of the furnace and how to regulate it; but after this was done the results were beyond our expectations.

In the charcoal furnace the crucibles were set on an iron plate, 15 at a melt, and charcoal was packed all around and on top of them. The first melt, starting with a comparatively cold furnace, would take about 45 minutes, while subsequent melts would take a little less than 30 minutes. In the wood-furnace, the muffles, which are Denver UU size, hold twenty 20-gram crucibles each, but this is too many to run, as the charges in the front crucibles will not melt down. The best number for a charge has been found to be from 12 to 16 in each muffle, and if the front parts of the muffles are filled with charcoal or coke, the first melt of from 24 to 32 crucibles can be finished in about an hour, and subsequent melts in about 35 minutes. Cupellation takes about the same time as before. Besides its larger capacity, the furnace is cleaner and more convenient to operate than the charcoal furnace.

With an average run of about 30 assays per day, eight bushels of charcoal, costing about $1.88, were formerly required to melt the charges and cupel the buttons. With the wood furnace, during a period of about two months, an average of one cord of limb wood per week was burned for approximately the same average number of assays. The cost, therefore, for wood was $0.93 per day during this period, and an average saving of $0.95 per day was effected in fuel with the use of the muffle furnace. An additional saving is made in crucibles and crucible covers, as the latter are not used at all, and the former last twice as long, on an average, when used in the muffles as they did when placed directly in the burning charcoal. While this saving can be determined only approximately for the short period that the furnace has been in use, it is not less than $0.15 per day. The increased cost of muffles can be determined only approximately, for such a short period, but so far this item has amounted to about $0.10 per day. There has resulted, then, from the operation of the wood-burning furnace a net saving in fuel and supplies of close to $1 per day.

The total cost of the furnace, installed, was $370.77. This included the expense of excavation and of a wood-shed. The cost, of course, would be much less in a less remote district, as the freight on the furnace from Denver to Bodie amounted to nearly three times the price of the furnace at Denver. It will be seen, then, that as an expenditure of $370.77 has resulted in a saving of $1 per day, the furnace was a good investment.

The fear, which was at first entertained that from the combustion of the wood available for use here a sufficiently high temperature could not be obtained for melting the charges to a good, thin slag, has proved to be groundless. I venture to say that almost any sort of medium-grade wood can be used successfully in these furnaces for assaying, as there is probably not a poorer grade of wood used any place than the variety of pine used in the instance described.

Hudson Bay.—William Beech has returned to Winnipeg after an extended prospecting trip on the shores of Hudson Bay and reports important discoveries of minerals. Within a few miles of Fort Churchill there are valuable plumbago deposits. Mica abounds in some of the rocky districts where both the white and brown varieties are found. Six miles from Fort Churchill, Mr. Beech found iron ore on the shores of the bay, samples of which he procured for analysis. He is the first man to stake out a mining claim on Hudson Bay and register it with the Dominion government, having located deposits of mica, iron and plumbago. The Hudson Bay factor showed him samples of gold which had been brought in from time to time by Eskimos and explorers, and he learned that copper abounds in the vicinity of Chesterfield Inlet, where it is chopped out of the rock in large chunks by the natives. Others are prospecting in the same region. Mr. Beech returned part of the way on snow shoes and the remainder of his journey by a Hudson Bay Company dog train. He will return and prosecute further researches when navigation opens.—American Manufacturer.

Special Correspondence.

LONDON, May 2.

The directors of Dolores, Ltd., have issued a circular containing the particulars received from Dolores Mines Company, for the six months, July to December, 1905, showing the monthly totals of crude ore milled, the average assay-values thereof, the average values recovered therefrom and left in the tailing, and the operating costs per ton with analysis of same under the customary heads, together with a statement of the total receipts and expenditures on revenue account for the seven months to January 31, 1906, audited in New York, of which the following is a summary:

Total Receipts:

On Bullion sold from treatment by amalgamation only of 4117½ tons crude ore milled	$267,996.70	
Sundry	1,548.67	
		$269,545.37

Total Expenditures:

Mining	$15,315.53	
Reduction works	39,009.91	
Bullion shipping	21,807.36	
Office and general	23,805.75	
		99,938.55
Total net profit at the mine (7 months)		$169,606.82

The average recovery per ton (amalgamation only) is seen to be slightly over $65. The monthly average gross value left in the tailing for treatment by the cyanide plant, when ready, ranged from $48.57 to $26.14 per ton. The highest monthly average gross assay-values per ton were: Gold 2.80 oz., silver 93.70 oz. and the lowest 1.56 oz. and 65. oz., respectively. Taking November as a specimen month when the largest quantity was put through the mill, the operating charges amounted to $17.77 per ton, made up of development $0.01, mining $2.38, amalgamating $7.20, administration $1.77, maintenance $0.08, general $2.24, shipping and selling (bullion) $1.82 and duties plus taxes $2.27.

With regard to mine development, the report states that during January the third (lowest) level was advanced north 30½ ft., the face sampling for the month averaging $89.64 per ton for a width of 5 ft. 10 in. At the end of the month the face showed assays of $129 to $318 per ton. The same drift was advanced 24.3 ft. in February, the face sampling showing an average assay of $180.88 per ton over the width of 4 ft. 9 in. During February the main shaft was sunk 10.1 ft., the ore coming from this giving an average assay of $22.18 per ton.

The record of mine extraction for January shows an average width of ore in the seven blocks in course of stoping, of nearly 7 ft., and for February the average width shown in the five blocks stoped is nearly 8 ft. It is pointed out that these averages of actual stoping widths compare with 4.7 ft. and 5 ft. respectively, as estimated for the same blocks in the original valuation of the ore reserves, also that as compared with the original valuations of $42 per ton average, the dump is also showing up well. In January the 230.1 tons of dump ore sent to the mill averaged $70.83 per ton, and in February 86.17 tons milled averaged $86.49 per ton.

The directors of Esperanza, Ltd., in issuing their second annual report, covering the period from November 1, 1904, to December 31, 1905, congratulate the shareholders on the phenomenal yield of gold which the Esperanza Mining Company has obtained during that period, and also on the rich returns which the consulting engineers indicate will be recoverable in the future. In this same period dividends were declared amounting to £375,375, equivalent to 82½ per cent on the capital of the company, and the directors state that very much larger dividends may be looked for during the current year.

The balance sheet of the Esperanza Mining Company shows assets readily realizable after providing for current liabilities of $2,451,969 including undivided profits at December 31, 1905, of $2,159,988.74, out of which the final dividend for the year, absorbing $1,203,750 has been paid. The sums of $239,141.58 spent on construction (including the recent complete electrical power equipment at the mine), and $61,392.60 for prospecting on the Suceso property, amounting in all to $300,534.18 since the formation of the Company, have been entirely written off revenue. The directors invite attention to the extraordinary developments which have occurred in the mine during the period under review. On June 15, 1905, Mr. Harold A. Titcomb made the first interim examination of the ore in reserve on these veins, and reported a profit in sight amounting to $1,881,000. On August 30, 1905, Mr. Cortlandt E. Palmer made the second interim report and advised the net profit on the ore reserves in sight as $5,621,338, and a further $2,611,577 as probable ore reserves. From the annual report of the consulting engineers it appears that they estimated on December 31 there were 127,240 tons in reserve, which should yield a profit of approximately $5,261,110. No estimate of the value of probable ore reserves has been made in this report, but recent developments point to the probability of opening up further extensive ore deposits, not only in direct continuity with those already being worked, but in other parts of the mine as yet only partially explored.

The audited statement of accounts for the period mentioned shows a profit of	£384,143.0.6	
To which is added the amount brought forward from last account	2,122.0.7	
Making a total of	£386,265.1.1	
This amount has ben appropriated as follows:		
Dividend No. 4, Feb. 11, 1905, 6d. per share	£ 11,375	
Dividend No. 5, May 15, 1905, 6d. per share	11,375	
Dividend No. 6, August 16, 1905, 6d. per share	11,375	
Dividend No. 7, Nov. 14, 1905, 6d. per share	11,375	
Dividend No. 8, Nov. 14, 1905, 4s. per share	91,000	
Dividend No. 9, Jan. 22, 1906, 6d. per share	11,375	
Dividend No. 10, Jan. 22, 1906, 10s. per share	227,500	375,375.0.0
Provision for income tax on dividends paid to English shareholders on No. 4 to 8		3,584.12.9
Leaving a balance (which it is proposed to carry forward) of		7,305.8.4
		£386,265.1.1

The actual value of the bullion extracted from the mine for the 14 months under review, is reported at $5,341,867.

Since the issue of the annual report the following particulars relating to the current year have been published, as received from the Esperanza Mining Company:

	Jan. & Feb.	Mar.
Tons of dry ore crushed	26,008	13,647
Shipped to smelter	11,123	4,713
Tons of dry ore:		
Value of Bullion produced	$263,242	$130,442
Value of Concentrate	81,546	59,696
Value of Ore shipped to smelter	851,450	332,284
Sundry receipts	284	1,492
Working expenses and depreciation	506,296	234,426
Profit at the mine	690,226	289,488

The London office note appended to the March report refers to the difficulty arising out of shortage of railway-cars, as continuing in aggravated form, the diminished tonnage being entirely owing to this fact.

The directors of the Mexico Mines of El Oro in a report which they have just issued state that Mr. R. M. Raymond has advised that, in view of the highly satisfactory development which has taken place during the past six months in the No. 5 and 6 levels, he is of opinion that the amount of ore now exposed in the mine fully justifies the immediate erection of a 20-stamp mill, having a crushing capacity of 100 tons per day, and suggests that a little later it may be advisable to add 10 or 20 more stamps to the mill he now proposes to erect, thus doubling its capacity. The developments at the No. 5 level have been extremely satisfactory; in the course of the drift north it has encountered, in a section of the vein which was barren in the upper levels, an orebody which has so far been proved for a length of 130 ft., having a width of 20 ft. and giving an average value of $20 gold and 9 oz. silver per ton. This drift is now entering the extensive orebody which was developed in a northerly direction in the levels above, with every indication that it will be found productive on the No. 5 level. Not having succeeded in making arrangements as formerly contemplated, with El Oro Mining & Railway Co. for the use of their mills, the directors have decided, in accordance with Mr. Raymond's advice, upon the immediate erection of a 20-stamp cyanide mill, with tube-mills and other modern devices, which are necessary to insure high extraction from the ores of the Mexico mine. The report states that in the meantime Mr. Raymond is proposing to ship to smelters a portion of the high-grade ore developed in the No. 3 and No. 4 levels, which has an assay-value of from $80 to $100 per ton, and the proceeds of such shipments, together with the present cash resources of the Company, will, it is estimated, be sufficient to carry on all development work and complete the erection of the mill without the provision of further funds.

The death is announced, after a short illness, of Mr. Matthew James Burn, formerly a well known figure in connection with West Australian, and more lately with Mexican, mining companies. Mr. Burn possessed a bright intellect, coupled with an engaging personality; he will be greatly missed by a wide circle of friends not only in this country but in the Colonies and the United States. His numerous clients were always able to look to him for safe guidance through the mazes of English company law and practice. The other partner in the firm, Mr. T. D. H. Berridge is one of the new Liberal M. P.'s, he having defeated Mr. Alfred Lyttleton, Colonial Secretary under the late Unionist Government, at the last General Election.

SALT LAKE CITY, May 7.

The shipments of ore from Tintic district last week amounted to 207 cars, the shippers being: Ajax, 3; Beck Tunnel, 6; Black Jack, 4; Brooklyn Consolidated, 4; Bullion-Beck, 13; Carisa, 5; Centennial-Eureka, 57; Dragon Iron, 9; Eagle and Blue Bell, 10; Eureka Hill, 10; Gemini, 31; Grand Central, 6; Lower Mammoth, 2; May Day, 7; Mammoth, 18; Scranton, 2; South Swansea, 2; Swansea, 4; Uncle Sam Consolidated, 3; Victor, 4; Victor Consolidated, 1; Yankee Consolidated, 6.

The Beck Tunnel Consolidated and Mammoth Mining Co., both operating in Tintic district, have declared dividends for May to the amount of $25,000 each.

The management of the Lower Mammoth mine, in Tintic district, has decided to sink the main working shaft to 1,800 ft., it now being down 1,200 ft. The winze below the tunnel, now down to the 1,600 level, is to be sunk 100 ft. deeper. Extensive bodies of shipping and milling ore have recently been developed on the 1,600 and other levels.

The Bingham Central Mining Co. has added the Bonham and Protection claims to its Bingham estate.

The governing board of the Salt Lake Stock and Mining Exchange has listed the active Nevada stocks which were called on the San Francisco exchange before the recent earthquake and fire.

The Boston Consolidated Mining Co. has a large force at work on the site of its new mill near the town of Garfield, Salt Lake county, which is to treat 5,000 tons of ore per day. The carpenter-shop and warehouses are well along in construction, and excavations are being made for the power-house, machine-shop and officers' mess-house. The excavations for the main mill-building will be started before June 1. The contract for the structural steel was recently let to the Minneapolis Steel & Machinery Company.

The construction of the new mill of the Utah Copper Company, at Garfield, is progressing rapidly. The steel for the first unit, which will contain equipment necessary to handle 3,000 tons of ore daily, is arriving. The power-house and lesser buildings are taking form, some of them being completed.

The Yampa Smelting Co. has placed an order for several additional MacDougall furnaces, making a total of eleven. In addition to this, there are two Edwards furnaces in operation. The plant will soon be equipped to treat 1,000 tons of ore daily. Changes made during the past year seem to have overcome many of the difficulties experienced in the past, and the plant is now being operated successfully and the company is making money—the returns being more than $100,000 per month, these figures having been given out recently from an official source. The company has secured practically all the land it needs for the building of a 12,000-ft. aerial tramway, which will connect the mine and smelter, and an order will soon be placed for this equipment. At present the company depends on the Copper Belt railroad for movement of ore.

Indications point to the rapid development of the Deep Creek district, along the western borders of Utah, the building of the Western Pacific railroad westward

toward San Francisco contributing largely to this end. Many prospectors have gone in during the past few months, and late developments, particularly in the Clifton section, have been of an important character. In the Gold Hill mine, owned by Salt Lake men, extensive bodies of copper ore have been developed. There are good reasons to believe that the great activity in western and southern Nevada is graduaHy making its way eastward.

A deal was closed in Salt Lake, a few days ago, whereby the Douglass group in Mason Valley district, of Nevada, which has produced extensively in the past, was purchased by Walter C. Orem, manager of the Utah Apex Mining Co. of Bingham, and Frank J. Hagenbarth, of Salt Lake.

The Big Indian copper mine, situated in La Sal mining district, in eastern Utah, has been bonded to Samuel Newhouse of Salt Lake. Auguste Mathez has been delegated to make an examination of the property.

The deal pending for sometime, looking towards a consolidation of the Comstock and California mines at Park City, has been consummated. A new company has been organized, to be known as the C. C. Consolidated. H. A. McCornick, is president; W. F. Snyder, vice president; S. A. Whitney, treasurer, all of Salt Lake. Both properties are fairly well equipped. the California having a mill of 100 tons daily capacity.

The Daly-Judge Mining Co. operating at Park City, has paid off $20,000 more of its improvement bonds, leaving only $80,000 yet uncancelled. Since January 15th last, $129,000 has been applied in reducing the bonded indebtedness. Besides, a little over $22,000 was used to wipe out an over draft. Ore shipments since the first of the year have netted between $40,000 and $50,000 monthly.

A mining deal was closed in Salt Lake a few days ago which will involve the transfer of the Lost Packer mine in the Loon Creek, Idaho, district, to J. A. Czizek of Salt Lake and associates. A new company, to be known as the Lost Packer Mining & Smelting Co. will be organized.

DENVER, May 12.

The matter which is commanding the attention of the Denver people at present is the question of granting or withholding franchises to the various public utility corporations. The Rush bill, under which a charter was granted to the city and county of Denver, provides that all franchises must be granted directly by the tax-paying voters. This is a good idea, but it has its faults. The trouble is that there is no way for the people to negotiate with the corporations. The corporations present a proposition. The people must either accept it, or wait another year and have the same turmcil all over again. There is no way provided for the people to submit a counter-proposition. The corporations take advantage of this fact and ask for more than they are entitled to. The tramway company is evidently paving the way for a coal-distributing scheme in the city. In addition, they make lurid promises about extensions, but when it comes to agreements in writing they nimbly side-step. The gas company wants 20 years more of clover and, some people think, they do not offer as much as they ought to in return.

There was a bad fire Friday, May 4, at the plant of the Colorado Glass Works. The plant was razed to the ground.

The American Smelters Securities Co. have ordered the mill at the Silver Lake mines at Silverton to be re-built. H. A. Guess, the manager of the property, says the new mill will be larger and better than the old one. It will be recalled that the Silver Lake mines made Edward Stciber in a financial way, and Edward Stoiber made the Silver Lake mines. Mr. Stoiber's death and the burning of the mill occurred practically at the same time.

The tonnage at Cripple Creek has fallen off considerably of late. This is due to a number of causes, prominent among which are the burning of the Portland shaft, the flooding of the El Paso, the exorbitant rates being charged on ore reduction and the interest being taken by Cripple Creek operators in Nevada mines. Those acquainted with the camp look for an increase in production next faH. One gratifying feature of recent development is the way new orebodies are being discovered in depth. The Elkton has just found a new vein which was unknown on the upper levels and the El Paso was developing a rich shoot on her lowest level when a water-course was cut that flooded the mine to the level of the drainage tunnel.

The Portland and Stratton's Independence seem inclined to lock horns in a lawsuit over some ore alleged to have been removed from Portland ground by Independence lessees. If the matter comes before the court some interesteing light may be thrown on the question of the extent of responsibility which rests on the mining company for the deeds of its lessees.

Leadville has developed a wonderful tonnage of medium-grade ore in the last few months and has also proved that the days of rich ore are not past, the Bessie Wilgus discovery being exceptionally high-grade. All that territory between the town and the Mesquito range is attracting the attention of mining men. The discoveries in the Yak, the Bessie Wilgus and in the properties along Big Evans gulch warrant the opinion that Leadville may surpass all previous records in the matter of production. Meanwhile Judge Owers and his associates are trying to prove that the other side of the camp is just as good or better, by sinking a deep shaft to reach ore disclosed by diamond-drill borings.

There is quite a big strip of mineral country on the other side of Mesquito range from Leadville and everyone wonders why the production is not greater. This summer's work may dispel all doubts, for it is likely that there will be a production consistent with the great extent of mineralized land and the favorable formation. From Hartzell to Dillon there is a continuous belt of mining territory and a small yearly output. When one considers that this belt is 45 miles long and 5 to 15 miles wide and that in it are some high-grade mines and also some large bodies of low-grade ore it seems as though the production should be much greater. The trouble seems to be that the big and continuous bodies are hard to treat and the high-grade ones are pockety. I must not give the impression that there are no profitable mines in the belt, because what started me on this line of thought was noticing the declaration of a $17,000 dividend by the London mine the other day, and there are several others that are large producers; but there ought to be more, and, as suggested above, there are two or three large enterprises afoot in this belt which may change the complexion of things. I hope to be able to publish fuller information later.

DENVER, May 10.

Clear Creek and Gilpin counties are securing more and larger investments in their mines than for years past. New enterprises are being started and properties are changing hands at a lively rate. Not only are the more recent discoveries in demand, but mines that have not been worked for years are being cleaned out and exploited.

Aspen capitalists have recently secured the Maggie M. group in Eureka district, Gilpin county, and intend developing, through the St. Anthony shaft now 170 ft. in depth. A hoisting plant has been installed and buildings are in course of erection.

It is reported that the Caledonia vein has been cut by the New National tunnel near Black Hawk. The vein was encountered about 2,200 ft. from the tunnel portal at 600 ft. in depth and is said to carry a large body of both milling and smelting ore.

The Banta Ranch mines of Gilpin county, owned by the Pleasant Valley Mining & Milling Co., have been idle for many years. Last fall work was commenced on transportation and milling facilities and carried forward until now the company has its 100-ton concentrating mill in operation. It has commenced shipments from the mines of smelting ore and is making concentrates of about a $30 grade at the mill.

The Gregory-Bobtail, Fisk and Cook mines of Russell gulch have been consolidated and the owners are planning to operate the consolidated properties on a large scale. These properties are credited with a gross output of about $20,000,000. It is reported that Chicago capitalists have purchased the West-Calhoun, Jefferson & Capital Prize mines located in Leavenworth gulch and Quartz hill. Active development of these properties will be started at once.

Nevadaville parties have commenced the development of the Silver Plate mine, associated with Wm. Thompson, the owner. The Silver Plate mine on the Thompson ranch, Eureka mining district, was discovered over twenty years ago and was chiefly famous for the fine specimens of silver nuggets it produced. The vein is small and carries high-grade silver ore, running from 800 to 900 oz. per ton.

The work of re-timbering the Cosmos tunnel of the X-Ray Mining Co. near Georgetown has been commenced. The Magnet group will hereafter be operated through this tunnel. As soon as the tunnel is timbered and connections made for ventilation a large production is expected from known bodies of ore.

It is reported that the Kelly tunnel near Georgetown will soon be started. The property has changed hands and the new owners have arranged to pay off the indebtedness of the old company and continue the tunnel, which is now 3,000 ft. in length, under Democrat mountain and nearing its productive area.

A contract of 5,000 ft. has been let on the Seaman tunnel, located on Fall river in Clear Creek county. The bore is to be 8 by 8 feet, and the agreement calls for 200 ft. driving per month. The Continental Mines Power & Reduction Co. projectors of the tunnel have ordered a plant of machinery consisting of 80 h. p. boiler, air compressor and air drills and suitable buildings are being erected.

The Seaman tunnel project, which has been under consideration for several years is of considerable magnitude. The portal of the tunnel is situated on Fall river at an altitude of 8,850 ft. The line of the tunnel projected for five miles, is toward James Peak and crosses the mining camps of Lombard, Alice and Yankee. It will cut James Peak over 5,000 ft. in depth.

While the estimates indicated that notwithstanding, the forced reduction of tonnage, of some of the large producers of Cripple Creek, the output would be up to the monthly average, the compiled returns show a falling off of 2,000 tons less than March production. The totals from treatment plants show 46,000 tons, valued at $1,370,900.

The Cripple Creek drainage tunnel enterprise is yet a matter of contention among mine owners and the date of starting the bore is postponed from time to time. It has been noted by some observers that a number of the drained mines, that is, those drained by adjoining deeper works have produced deadly gases to a greater extent than the wet mines. Under certain atmospheric conditions these gases issue from the courses and crevices from which water formerly came. At times parts of the mines have to be abandoned, temporarily, and until there is a change in the weather.

It is stated that the Dorcas mill which was destroyed by fire early in April will be rebuilt by J. M. and Frank Homer. The Dorcas mill, cyaniding plant located near Florence, Colorado, was generally believed to be operated independent of any trust and enjoyed a large patronage from lessees in the Cripple Creek district. It is said that the new plant will be housed in an all steel, fireproof building. The entire plant will cost about $300,000, and have a capacity of 200 tons daily.

A sale of the Suffolk-Globe group and 40-stamp mill of mines, near Ophir is pending. The prospective owners propose to spend $50,000 in developing the property and remodeling the mill. The mines will be operated through the Badger tunnel, which will cut the veins from 800 to 2,000 ft. in depth.

It is stated that the order to rebuild the Silver Lake mill near Silverton, which was recently destroyed by fire, has been countermanded by the American Smelting & Refining Co. It is believed that the fire was of incendiary origin, but no arrests have been made.

JOHANNESBURG, April 10.

Nothing approaching a panic has been caused by the recent troubles with the Zulus in Natal. The Liberal Party has added to its unpopularity in South Africa by its interference with Natal. The leading natives in the recent trouble were condemned to death for the murder of several white police. The Home Government interfered, and the Natal Ministry promptly resigned. Then the Home Government precipitously "climbed down," and the Natal authorities were allowed to deal with the guilty Zulus, whom they shot forthwith. Although the situation is considered serious, the white people of this country feel quite capable of dealing with it. The Zulu troubles in Natal have had no effect on the market, because, some say, it is in such a rotten state that nothing will affect it. The British are the most sentimental people in the world, and in their dealings with the black races of South Africa, there has been far too much kindness, and not quite enough of the severity characteristic of the Boers and the Germans. Just now sentiment must be put aside, and the recalcitrant natives dealt with severely. There are few Zulus employed on the mines of the Rand, so that the disturbances will not affect the labor supply here.

An annual meeting of considerable interest was that of the South African Land & Exploration Co., commonly called "Sallies," held last week at Johannesburg. "Sallies" had a most sensational run on the Stock Exchange some months ago, when the £1 shares went to £7 or £8. Today they stand at 17s. 6d. According to the chairman's remarks, their tin mine promises to develop into a profitable enterprise.

Tin is not the only base metal receiving attention. Copper and lead have come in for their share. As far as prospects are concerned, one hears of them every day, but whether they will develop into payable copper mines remains to be seen. There is one promising lead proposition on which a lot of work has been done. The budding base-metal industry is even more harmed by the uncertainty of the labor supply than the gold and diamond mining.

There have been two important developments lately.

The most important and most satisfactory is that of the Cinderella Deep, where the reef was encountered by the vertical shaft at a depth of nearly 4,000 ft. The assay-values show highly payable ore. This mine is under the technical control of Messrs. Denny, who will introduce some of their novelties in its development, such as conveyor-belts for handling the material on the inclines, etc.

At the Knights Central (a mine of the Central Rand) the reef has been found at a depth of about 2,250 ft., the assay-values being fairly satisfactory.

BUTTE, May 12.

The water problem, once a serious handicap and inconvenience to mining in the Butte district, is solving itself. Big Butte mountain, which several years ago appeared to be saturated with water, is being drained dry, and the amount of water that is now pumped from the mines is small in comparison with that of some years ago. All of the Anaconda mines are being drained through the High Ore mine, from which 1,000 gal. per min. are now pumped, where formerly five to six times that quantity was raised. The High Ore drains the Anaconda, Bell and Diamond, Wake-up-Jim, Neversweat, St. Lawrence, Sunnyside, Mountain Consolidated, Green Mountain and several other mines. Even mines in the lower part of Butte district, among them the Ophir, Emma, Belmont and Pittsburg, have only a small fraction of the water that they formerly had to contend with.

The East Butte Mining Co.'s main shaft, on the Dutton claim, has reached a depth of 400 ft., where a pump has become necessary. It is expected that a depth of 500 ft. will be reached within a month, when cross-cutting will be started. In two months the company will be able to hoist ore from the shaft, while sinking will continue to 1,000 or 1,200 ft. Mr. Wall, the manager, says the company will have a daily output of 500 tons of ore by the first of next year, independent of lessees. The latter are now mining a lot of good ore, on which they are paying a royalty of 25%. Lessees are also operating the company's concentrator and are working up the old dumps at the mines, which yield 2 to 4% copper. Some ore is being hoisted that runs from 30 to 35% copper. It comes from a four-foot vein in the Simons mine, which is also worked by lessees.

The smelter of the Montana Ore Purchasing Co. will not be shut up by the new owner, the Butte Coalition Co., but will continue to handle all the smelting ores from the Rarus, Minnie Healey, Corra and Belmont mines. The combined output of the four mines is about 1,500 tons per day. The Corra has become the company's principal producer, in point of quantity. A big vein was recently opened in the Corra and the output from the mine is increasing.

The South Butte Copper Mining Co. owns eight claims in the southwestern part of Butte district and has started sinking a shaft to 500 ft. It is claimed that there are several copper-bearing veins in the ground.

The Butte Copper Co., which is developing the Trifle and Anselmo claims in the western portion of the city, is running a cross-cut from the Trifle shaft to the Anselmo vein. In this work a lot of fine copper ore has been taken out. The shaft of the Butte & London Co. on the Greendale claim has reached a depth of 300 ft. and will be sunk to 1,200 ft. before exploration work is begun. The new hoisting plant, boilers and air compressor are being installed. The company has erected a number of buildings at the mine and has moved its offices there. No ore has been struck in the shaft, but there is a considerable flow of water, which, so far, the pumps have had no difficulty in handling.

New hoisting machinery is being put on the three shafts of the Butte & Bacorn properties.

In the Original mine, one of the Clark properties, the big vein, which has been cut at the depth of 2,200 and 2,400 ft. in the Anaconda, has been cut at 1,900 ft., where it is 20 ft. wide, and the ore runs high. The Original shaft is down 2,000 ft. and a cross-cut is being run from that point to the vein. The same vein runs through the Parrott and other ground lying between the Original and the Anaconda.

The North Butte Mining Co. expects to have its new engine and hoisting plant in working order in 60 days. All the machinery for it is now on the ground.

The shaft of the Butte Copper Exploration Co., on the Six O'Clock mine, has reached a depth of 550 ft. and is being sunk at the rate of 25 ft. per week, and will be sunk to 1,000 ft. before cross-cutting.

The vein recently cut in the Bertha mine, east of the Pittsburg mines, at a depth of 35 ft. in a winze, has also been cut in the bottom of the shaft at 100 ft. The two openings are 500 ft. apart, and shipments of ore are being made from both. The vein has been opened 80 ft. north and south. This discovery of ore in commercial quantities in the Bertha has stimulated mining on the east side.

The Butte & Veronica Mining Co., recently incorporated in Butte, owns 12 acres of ground west and south of the Belmont mine, owned by the Butte Coalition. There are two shafts from which samples of good copper and silver ore have been taken. One shaft is 70 ft. deep and the other 130 ft.

Mayor John MacGinniss, of Butte, and several associates have purchased the Copper Bell mine in the Cataract district of Jefferson county, and preparations are being made to work the property. The Copper Bell is situated seven miles north of the town of Basin near the Eva May, a mine that has been a producer for many years. The Copper Bell has been idle since 1894.

The East Butte Extension Co. made a shipment of 12 tons of ore a few days ago which returned 19% copper, 15 oz. silver and 40c. gold per ton, making a net return of $57 per ton. This ore was extracted by two men in five days. The Butte-Milwaukee Co. is sinking a shaft on the Florence mine, one of the two properties recently acquired. Lessees of the Pollock mine, an old producer, will be shipping ore soon. The North Butte Mountain Co. is sinking a shaft on one of its claims in the new district north of Walkerville. Two bars of gold have recently been shipped by the Cable Consolidated Co. and a bar weighing 135 lb. was shipped a few weeks ago. The Butte and Summit Valley Co. is exploring copper properties in Saratoga gulch, southeast of Butte, where a great deal of development work is being done by various companies and individuals.

CALUMET, May 12.

It is understood that the Calumet & Hecla Mining Co. has purchased the old Nonesuch property, in Ontonagon county, which was owned by A. K. Camp of Milwaukee, Wis., and others. Official information on the subject is unobtainable. The Nonesuch mine is the principal and pioneer property in the Porcupine Mountain district, and consists of a tract of one square mile at the southern end of the Porcupine Mountain copper range. Discovered in 1865, the mine was first opened in 1867. The lode is an argillaceous, conglomeratic sandstone. Numerous attempts were made to place the Nonesuch upon a paying basis in the early days of the Lake copper industry and many and varied were the schemes tried to save the fine copper which it carries. The property is said to be as rich in copper as the Calumet & Hecla, but the metal is very fine, something like the flour gold of the Western miner. Under Calumet & Hecla Co. management the Nonesuch is assured of a fair trial. The acquisition of property in Ontonagon county by the Calumet & Hecla Co. is highly pleasing to residents of that section.

It is expected that the Victoria mine will start shipping to its mill this month. Construction work on the mill was delayed by the non-arrival of materials. The Taylor hydraulic power plant at Glenn Falls is proving successful. Underground the Victoria management has been cutting out stopes the last few weeks and it is stated that the ore is better than was indicated by the character of ground penetrated in the drifts. With its water-power plant in operation, it is thought the Victoria should be able to mine and mill a ton of rock at less expense than any other property in the Lake Superior copper district.

The Northern Construction Co. has been awarded a contract for building a large warehouse, assay office, etc., at the Champion Copper Co.'s stamp-mill on the shore of Lake Superior. Excavating for the foundations of the new buildings is progressing. The new structures are to replace those destroyed by fire some time ago, when all the records covering the experimental work of the last few years were destroyed.

Surveyors in the employ of the Calumet & Hecla Mining Co. have been at work the last few days on the property recently acquired by that corporation northeast of the Mohawk mine, and it is understood that an early start will be made in exposing the Kearsarge amygdaloid bed at that point. The lode passes through five forties of the property. Some of the Eastern officials of the company have recently looked over the ground. The tract includes 240 acres, lying northeast of the Mohawk, and adjoining the Seneca, owned by the Bigelow syndicate. The ore in the Mohawk's northernmost shafts is reported to be excellent, and it is probably this fact that influenced the Calumet & Hecla in its acquisition of the property. The development of these lands will be highly important to the Seneca and may lead to the inauguration of activity there within the next year or so.

Construction work on the new steel shaft and rockhouse at No. 3 shaft of the Wolverine is advancing rapidly. The Wisconsin Bridge & Iron Co. of Milwaukee, Wis., has the contract. The structure will replace that destroyed by fire a few weeks ago.

MINING SUMMARY

ARIZONA.

COCHISE COUNTY.

The progress made at the mill of the Tombstone Consolidated Co. is exceeding expectations and is paying a royalty to the company. During the past month the cost for treatment of ore put through the mill was $1.50 per ton, which, when the remaining stamps are started, the management expects to reduce to $1 per ton. At the present time a little over 100 tons per day is being put through which amount will soon be doubled. When the mill was started it was thought that the four Callow tanks would be sufficient to carry off the slime, but they were found insufficient and six additional tanks were ordered. These have been put in place and 20 more stamps can now be started. Several bars of gold and silver have already been shipped as the result of the clean-up and two cars of concentrate were shipped last month. The present system of milling is resulting in saving 90 per cent. The ore comes from the main shaft and is being taken from old stopes of the Contention and Head Center workings and it is said that there is enough ore in sight to keep the mill running for a number of years without further development.

A Los Angeles company has been formed to take a group of claims in the Johnson district, and has paid down ten per cent of the purchase price, and will start development. This includes the Teaser, Surprise, Hillside, and other claims. The group was formerly the property of T. K. Mitchell, K. Hart and others, and is situated in the center of the district. Kirk Hart will have charge of the work.

MOHAVE COUNTY.

S. C. Bagg, who has been cleaning out the Jennie mine on the Arizona side of the river opposite Eldorado canyon, has completed the work and will now begin development of the property. The shaft, which was filled up, was found to be 110 ft. deep, with a vein five feet wide between well-defined walls. Several drifts from 20 to 100 ft. long were cleaned out. The orebody ranges from two to five feet in width. Some of the ore remaining in the stopes assayed two ounces gold and 1,200 oz. silver per ton, while hundreds of tons will run $20 to $50 per ton. A contract has been let to sink a new shaft 200 ft. west of the old shaft. Twenty-five sacks of ore have been shipped to the Needles smelter.

A large body of high-grade ore has been found in the tunnel on the Victor & Virgin mines, which is being rapidly developed. These are among the oldest mines in San Francisco district but until lately there had been but little development work done. T. Ewing, the owner, will continue development. John Binschaedler has a contract for 1000 ft. of development on this mine.

YAVAPAI COUNTY.

At 562 ft. the Black Hills mine, near Jerome, has struck a body of copper-iron sulphide, and are sinking now in solid ore.

CALIFORNIA.

AMADOR COUNTY.

A. W. Aiken, superintendent of the Climax mine east of Jackson, says the ten-stamp mill is running night and day. The vein is 12 ft. wide in places, and the ore shoot 600 ft. long. It is low grade, but all of it goes to the mill.—— The Mitchell is being operated by the lien holders, who obtained judgment for their respective claims, in the hope of being able to secure enough to pay something on the indebtedness. There was a pile of rock, estimated at 700 tons, left by the lessees. This is being run through the mill, it is said with satisfactory results.

It is locally reported that the Fremont Consolidated Mining Co., near Amador City, will add 60 stamps to their mill, making a total of 100 stamps. Large low-grade orebodies are developed in the several mines of this company, and it is believed that additional stamp capacity will lessen the cost of production in all branches.—The Kennedy mine struck a heavy flow of water last week. At one point fully two inches of water is pouring into the workings. It is encountered at a point in one of the lower levels where the east and west veins form a junction. The foot-wall vein in the 2,700-ft. level has been opened and four feet of it is found to be of fair milling quartz.

Two brothers, named Garbarini, were injured while working in the Kennedy mine Monday of last week by drilling into a missed hole. One of the brothers will probably lose his eye-sight. The other man was less seriously injured.

CALAVERAS COUNTY.

J. J. Rutledge, of San Francisco, has purchased the Lucas mine near Mokelumne Hill, and has been operating the same for three weeks. The suspension bridge across the Mokelumne river at the mine has been repaired sufficiently to allow ore cars to run over it to a ten-stamp mill.

Good reports come from the Ariel mine. The shaft shows ten feet of milling quartz, free gold being seen. —— The mill at the Josephine mine was completed last week. It is now crushing good rock.—— The hydraulic operations of the Nelson Contracting Co., at Calaveritas, have been temporarily suspended owing to striking a large body of cemented gravel which the stream from the giant will not disintegrate. Arrangements will be made for a mill to crusn the cement. The gravel is rich and the mine has been paying from the start.

INYO COUNTY.

In the White mountains the Neylon group comprises nine ledges, ranging up to 100 ft. in width, and many smaller ones. The value of the property is in the large amount of low-grade ore available. The lowest return has been 41 cents, the highest $17. Many pannings have been made and not one has failed to show gold. The group covers the north and east slope of a hill in Piute canyon, ten miles northeast of Bishop.

The three-stamp mill of the Mount Whitney Milling & Mining Co. near Lone Pine is finished. E. Walker is reported to have found a vein of high-grade ore on Walker creek, south of Lone Pine. The Goldike Reef mine is reported to have opened a four-foot vein at the 100-ft. level, averaging $200 gold per ton. A strike is reported in the Golden Gate claim in the White mountains.—The Casa Diablo Mining Co., near Bishop, has made final payment for the Sherwin mines. B. F. Brazee, of Cleveland, is president of the company. A mill and cyanide plant are to be built and running before October 1. The seven-mile pipe from Rock creek will first be laid. Much will depend on this additional water supply.

SAN BERNARDINO COUNTY.

It is reported that the Rose mine, 60 miles east of Victorville, on the summit of the north range of the San Bernardino mountains, is to be reopened. The Rose mine was worked steadily for a number of years prior to 1897. The ore is principally hematite in limestone, at contact with mica schist. The property has been leased to H. P. Starboard, who will rehabilitate the property.

SISKIYOU COUNTY.

The Gold Nugget claim at Empire Creek, Klamath river, owned by Carter & Taylor, is showing good prospects. It contains many large boulders, which have to be blasted out. The bed rock has a covering of rich gravel, and is easily kept clear of water by a steam pump. The Freshour Bar claim, in Virginia Bar district, has been closed down temporarily.—— New digging buckets are being made for the Yreka creek dredger, the first lot having been worn down.

TUOLUMNE COUNTY.

(Special Correspondence):—An organization to be known as the Tuolumne Mining Exchange, the purpose of which is to foster the mining industry of the county, has been formed in Tuolumne. The organization will maintain a permanent exhibition of ores, keep a record of mining properties, procure up-to-date maps, and, in fact, have available such other things and information as would be of interest to mining men. It will also have a room for the convenience of its members and visitors, where mining journals and other literature will be kept, and where writing may be done. The officers are J. T. Thompson, president; E. C. Damin, secretary, and J. W. White, treasurer.

It is reported that operations will shortly be resumed at the Goldwin, near Tuolumne. J. L. Partz is superintendent.

The breaking of the compressor at the Sunnyside mine has delayed work in the tunnel. Repairs will be made and work resumed. The face of the tunnel is within a few feet of where the vein is supposed to be.

J. W. Richards, superintendent of the Louisiana, reports the water lowered to the 250-ft. level, leaving 70 ft. yet to be unwatered. Progress will henceforth be slower, as considerable stoping and driving was done below the present level of the water.

A tramway is being constructed at the Lucky Find mine, near Confidence, and the mill is being put in readiness for operation.

The Dondero gravel mine, near Columbia, has been bonded to Stockton people. It is claimed that for the past several months the mine has yielded on an average $125 per day, with but a few men.

A number of people from Cleveland, Ohio, are expected to arrive here shortly to inspect the Columbus mine, one mile north of Tuolumne. At the North Star mine, near the Columbus, a new head-frame is being erected and the shafe re-opened. It is 215 ft. deep and is partially filled with water. J. W. Phipps, superintendent, states that as soon as the water is pumped out drifts will be started, and when these are well under way sinking will be commenced. Five men are at present employed. This mine has been idle for years.

The mill at the Longfellow mine in Big Oak Flat, near Groveland, after an overhauling, resumed crushing a few days ago.

The Spring Gulch mine, for some time past operated by Messrs. Connally, Vargas & Lundell, Tuolumne people, has been bonded to Eastern capitalists and preparations for working the property are in progress. A 2,000-ft. tunnel is to be run from Hunter creek that will tap the vein at a depth of 1,000 ft. The steam hoist is being repaired, new skips have been ordered, and the mill, which was never completed, is being put in shape and will be started up as soon as it is ready. Development work has been done to a depth of 500 ft. H. M. Shaw is superintendent and M. V. Connally is foreman.

The Pennsylvania shaft of the Soulsby mine, at Soulsbyville, is down 550 ft. and sinking continues. Work of unwatering the Davidson shaft is nearly finished. It will be sunk to 500 ft. and connected at this depth with the Pennsylvania.

Tuolumne, May 14.

COLORADO.

CLEAR CREEK COUNTY.

G. E. Collins, manager of the California mine near Central City, has been appointed general manager of the Newhouse tunnel, succeeding J. J. May. S. A Knowles, who has been in charge of the tunnel since Mr. May's resignation, will continue as superintendent, he having a contract to drive the tunnel 4,000 ft. Mr. Collins will continue in charge of the California mine, which has the deepest shaft in this section of the State. The California vein will be intersected by the Newhouse tunnel at a depth of close to 2,000 ft., and with but a limited amount of driving, connection can be made with the main shaft. The California shaft is 2,231 ft. deep, there being 23 levels. At the present time no work is being done on the property, the water standing above the 1,500-ft. level. Aspen people are interested in the Maggie M. group in Eureka district under lease and bond and have made arrangements for the operation of the property from the St. Anthony shaft, which is down 170 ft. and adjoins the Spur Daisy mine on the east. Machinery has been installed and it is the intention of the lessees to sink this shaft deeper. The group has produced high-grade milling and smelting ore from surface workings, and less than a year ago local lessees took good ore from the Spur Daisy workings. George Maloney is in charge.

A big vein is reported cut in the main tunnel of the New National Tunnel Mining Co. below Black Hawk, during the past week. The vein was cut at a distance of 2,200 ft. from the portal of this tunnel and is believed to be the Caledonia vein. It has been cut at a depth of 600 ft. and considerable shipping ore is expected from this tunnel. Lessees are working on another vein cut in the main tunnel and they are taking out lead ore. The company are also operating the Caledonia property in Lake gulch which is on the line of the tunnel, and are drifting on the east 450-ft. level and taking out smelting and milling ore which they are shipping at intervals. Shipments of smelting and crude ores, tailing and concentrate from Black Hawk to the Denver smelters and other points were 3,550 tons for the past three weeks. Included in these shipments, outside of the regular heavy shipments by the Chamberlain-Dillingham Ore Sampling Co., were the following lots to the Argo smelter: One car of smelting ore by the Santa Loreta M. & M. Co. on Bobtail hill, two cars of concentrate from the O'Neill mine in Gregory district, one car of concentrate from the Clear Creek Mining & Reduction Co., three cars of concentrate by the Fifty Gold Mines Corporation, operating at Black Hawk, and one car of smelting ore from the Dump mine on Bobtail hill to the Globe smelter, one car of smelting ore from the Druid property, in Willis gulch, and four cars of ore from the Concrete mine.

SUMMIT COUNTY.

The Old Union mill is running steadily and making regular shipments of zinc, lead, and iron concentrates. The compay is also shipping first-class zinc ore from their main tunnel. The Wellington mine is also shipping steadily car loads of zinc and lead ore assorted at the mine. Its second-class ore is being treated at the Old Union mill.—— The Laurium mine and mill on Bald mountain, above Illinois gulch has been bought by a new organization known as the Blue Flag Mining and Milling Co. The mill will be in operation early next month and the supply of good milling ore now on hand in the mine warrants the erection of additional stamps which will be added.—— The 40-stamp mill of the Jessie Gold Mines Co. is undergoing an overhauling, and renewal of worn parts. When this is completed the mill will be started on the ore which is broken in the mine.—— At Frisco the Excelsior mine is still making shipments of high-grade silver ore. The Square Deal Co. is making a trial shipment of milling ore as well as a lot of smelting lead ore.

The King Solomon Tunnel and Development Co. has run through another lead vein in their main tunnel. This is the best orebody cut in this tunnel, and is six feet in width. The Mary Verna and North American Cos. are making good progress with their big tunnels.—— At Montezuma good work is being carried on in several of the principal properties.—— The Pennsylvania mine is making regular shipments of smelting ore via. Keystone, and has a large quantity of mill ore in the mill and mine bins awaiting the starting of the mill when sufficient water can be obtained.

The Sarfield property is being energetically worked and good grade shipping ore sent to smelters. Campbell and Finotti are taking out fine lead and zinc ore from the Fisherman.—— The driving of the main tunnel at the Wild Irishman is being pushed as fast as possible.——The Blanton, Jumbo, Little Jumbo, Silver Eagle, Clarion, and several other properties are also being worked.—— The Rothschild Tunnel in Cooper mountain is now in 3800 ft.——At Robinson substantial development work is going on. The Krenger-McCoy Co. is developing the Wheel of Fortune mine which in the past produced largely.—— On Sheep mountain the principal properties being worked are the Snowbank and Michigan.——In the Eldora mine, the extension of the Robinson mine, ore shoots are found which in places measure from 30 to 50 ft. wide.——The Bonanza group, belonging to the Robinson mines, is now being worked by the Summit Mining Company.

The Felecia Grace has a hoisting plant in position and the company is sinking to the second contact. This group comprises the Champion, Homestake, and New York, all of which have been big producers in the past.—— The Ten Mile Leasing Co. has the deepest workings in this camp and is worked by Leadville leasers.

McNulty gulch is soon to be the scene of placer operations. This is a famous placer tract where a pound of gold per man per day was a common-thing in the 80's. Other properties which will be worked this season are the Columbine, Canyon Point, Half Moon and Jersey Queen. Molybenum, nickel, cobalt and tungsten prospects are also to be opened up.

Breckenridge, May 1.

IDAHO.

LEMHI COUNTY.

The Butte & Idaho Gold and Copper Mining Co. is to operate on an extensive scale. This company is successor to the Schumacher-Olsom Mining Co. The ground consists of six claims, a tunnel site and mill site, situated at the head of the north fork of Carmen creek, and joins the Ajax mines of Montana on the west, part of the claims being on the line of the continental divide and the State boundary. The Butte & Idaho has 550 ft. of development, and has done much other work. Last summer they built two and a half miles of new wagon road up Davis canyon, almost up to the main tunnel. They have machinery for a five-stamp mill, and have erected buildings. John Mengel is developing the Gold Cliff ground of seven claims in Kirtley creek, which he has under bond. The main tunnel is in 130 ft., and a new tunnel is being opened to prospect another and larger vein.

SHOSHONE COUNTY.

Articles of incorporation of the Little Sister Mining Co., Ltd., have been filed with the county auditor. The incorporators are: P. H. Renshaw, Shoshone county, treasurer; E. H. Pattison, F. Markwell, A. F. George and J. W. Bates. With the exception of the last named, who is a resident of Denver, Colo., all the incorporators are Wallace men.

Directors of the Alameda Mining Co. have levied an assessment. The group adjoins the Success, and is said to be on the Success vein. In a tunnel run 600 ft. a vein of high-grade galena was cut two years ago. Now the company will sink on it. The vein was 20 in. wide where it was cut 275 ft. from the surface. It assays 65 oz. silver and 67% lead, with considerable zinc.—— The O. K. Consolidated has men driving on its 400 ft. level. August Matt of Wallace is secretary of the company. The O. K. is a few miles below Kellogg.

MONTANA.

JEFFERSON COUNTY.

F. Walker, who, with Albright, has a lease on the Oro Cache mine, has pounded out in a hand mortar several pounds of gold from the quartz taken from the Oro Cache, which is the property of the Granite Mountain Co. The Oro Cache is one of the oldest mines in the State and the hill of that name is known to every old-time miner in the State.

MADISON COUNTY.

A rich strike of free gold ore is reported from the Mountain View mine near Stirling, an old camp. A company is being formed at Pony to develop and operate the mine.—The mining outlook for Madison county is promising. There is more activity at present than for a number of years. Many of the properties are being operated under lease. At Silver Star much work is going on in the mines. The Green Campbell Co. has about completed its mill, and expects to have it in operation by May 10. This company has large bodies of ore blocked out. In the vicinity of Sheridan there is a large amount of quartz mining by the leasing system. At Sheridan, on Wisconsin creek, placer mines are in operation by a company of Chicago men. Work has begun on a new flume which will be 2,554 ft. long.—Francis Redfern will develop his mines in Ramshorn gulch, particularly the Bedford. It is an old property and work has been done on it at different times during the past 20 years. The principal value is lead with silver and gold. The vein is 50 ft. wide, averaging eight per cent lead, with a streak which varies from three to six feet in width that runs 50% lead, 29 oz. silver and a few dollars in gold. All the ore taken out came from the surface to a depth of 70 ft. A shaft is down 148 ft. but it will have to be sunk 148 ft. further before it will cut the vein. It is Mr. Redfern's intention to resume sinking this shaft.—O. F. Fenner, operating the Mapleton mine under lease, is about to make a shipment of ore to the Washoe smelter at Anaconda. The ore is low grade.

NEVADA.

ESMERALDA COUNTY.

It is reported that L. Effinger has sold the Silver Peak mines which have, for years, been the property of the John I. Blair estate. The purchasers are nearly all residents of Pennsylvania. The deal has been under way for over a year. The Silver Peak group consists of nineteen patented claims, situated eight miles from the town of Silver Peak. During their period of operation they produced $1,500,000, but have long been idle. The principal Eastern men in the syndicate are Wm. Flynn and George T. Ilver of Pittsburg.

The Nevada Copper Co. is reported to have bought the Blue Jay group of copper claims, four miles east of Yerington. The property has been mined to a depth of 450 ft. and has several thousand feet of workings. Sixty men will be placed at work and a drift will be run through the mountain at a depth of 500 ft. in order to permit shipments of ore from the east side to Mason station, six miles distant.

Up to the present there has been little sought except copper in the region about Sodaville. Recently, however, there have been some rich finds of lead-silver ore, which promise to become important. These discoveries were made 23 miles northeast of Sodaville. The best strikes are made about 12 miles from Goldike.

LINCOLN COUNTY.

B. S. Hermson, who with Joseph Dederichs is building a smelter at Good Springs, has secured ground containing deposits of zinc ore. It is said the deposits are extensive.

LYON COUNTY.

The new camp fourteen miles west of Yerington, has changed its name from Gold Pit to Buckskin. A mining district was organized in Buckskin last week and a recorder elected. The camp is making headway toward a town, but the late stormy weather and inability to get supplies has retarded matters. The townsite contains 200 lots 25 by 120 ft. with 80-ft. streets and 16-ft. alleys, and nearly all of these lots have been sold or bargained for.

NYE COUNTY.

Freiberg camp is 125 miles east of Tonopah and 70 miles east of Clifford. Several strikes have been made there recently, just west of the old mines that produced largely in early days. Prospectors are rushing in and there is considerable excitement in the district. The ledges are wide and carry copper, lead, silver and gold. Several of the old properties have been bonded. There is plenty of wood and water, and the camp can be developed by means of tunnels. A new district, to be called the Valley View, is to be organized. Shoshone creek, near Round mountain, is also attracting the attention of prospectors. Many strikes have been made there during the past few weeks and several groups of claims have been bonded. The new head-frame at the Montana-Tonopah is completed, and the compressor has arrived.

(Special Correspondence).—Development of the property of the Manhattan Mother Lode Mining Co. is being pushed. The tunnel is in 75 ft., and two veins have been encountered, both of good size; the first vein returned assays of $23.96, the second ran $30. It is expected that 50 ft. further will encounter the first of the three large veins which outcrop on the surface above the tunnel. As this vein pans free gold on the surface, it is supposed that in depth good ore will be obtained. The other claims of the Mother Lode Co. in the Timber Hill section are showing up well. Men are actively engaged in opening up the 30-ft. vein on the Great & Only claim, and already good assays have been obtained. It is believed that this company has a good-sized milling proposition. C. A. Humphrey, a pioneer of Manhattan, has been elected president of the Manhattan Express Mining Co., and will personally supervise the development of the company's property. Men have been put at work exploring the large lode that outcrops on the property, as well as a contact between porphyry and schist which can be traced through the company's holdings. William B. Root, a Colorado mining man, has been put in charge of the property. The lode has been opened up and a good grade of quartz, which pans free gold, has been uncovered. A shaft is being sunk.

The 200-ft. vein on the property of the Consolidated Manhattan Mining Co., at East Manhattan, is reported to be improving. The tunnel which is being driven for the Pine Bird claim of the Consolidated Manhattan, is in 30 ft., and the entire face of the tunnel is in ore. Samples gave returns of from $2.40 to $16. When the tunnel reaches a point under the apex of the hill, which will give a depth of 240 ft., it will be in the center of the vein which traverses the property for 3,000 ft. The tunnel will be continued through the hill, and driving will be commenced at different points. A contract has been let for the mill. This property is situated between the Buffalo Mining Co. and the Manhattan Mammoth Co., each of which has uncovered high-grade ore. A compressor plant has been ordered for the Mammoth Company.

At a depth of 80 ft. in the shaft of Gregory No. 2 of the Manhattan-Nevada Gold Mines, a drift was started last week into the lode which crops on the crest of the hill. The ore assays from $5 to $60 per ton in gold. Bids are now out for a contract to drive a tunnel from the base of the hill to open up all the veins that traverse the company's holdings.

A stringer of rich ore was encountered a day or so ago, just off the line of the property of the Manhattan Cowboy Mining Co., trending into the Cowboy ground. The large vein of sulphide ore which was struck in the shaft on the Cowboy a few days ago is improving with depth; the sinking of the shaft is being expedited so as to get down to 100 ft., when driving will be commenced. An assay of $17.30 was obtained from the pyrites. The surface rights of leases 4 and 5 of the Iron King claim of the Manhattan Cowboy Co. have been let and the lessees will install dry washers to work the placer deposits on these two blocks of ground.

Manhattan, April 30.

OREGON.

BAKER COUNTY.

(Special Correspondence).—Mining interest in eastern Oregon is focusing rapidly on the copper belt east of Baker City, where the North American, under management of D. W. C. Nelson, is developing an orebody that is daily becoming more important. The double compartment shaft has now attained a depth of 250 ft., and the last 85 ft. of it has intersected a deposit carrying native copper, similar to those of Michigan. The rock which is now coming out is literally red with fine particles of copper which constitute about five per cent. It carries also about $5 per ton in gold and silver. The rush into the copper belt is on in full force. The Corpe ranch, lying to the northwest of Burkemont, has just been bonded to A. E. Snell, and it is reasonably certain that diamond drills will be exploring this ground within a few weeks. This ranch lies on a direct line between the North American and the Indiana mine and has an outcrop of copper-bearing rock, similar to that on the surface of the two properties mentioned. At the Snake river end of the belt, some Pennsylvania capitalists, having finally settled the prolonged litigation over the Iron Dike mine, are now pushing the development of that property. As an incident in this connection, a railroad from Huntington down the Snake to Homestead, on which work has already been done, will now be pushed to completion. Another road from Baker City down Powder river, for which surveys have been made and right-of-way secured, will tap the copper belt, just below Burkemont, and parallel it to the Iron Dike mine at Homestead, where it will intersect the road from Huntington. These prospective facilities in transportation will form an important factor in the present inrush of operators. It is difficult to say which is the cause and which the effect, the assurance of a railroad into this region, or the work that is now proving the copper deposits.

In the gold-mining districts near Baker City there is unusual activity also. Heavy snows that fell in March are stored in the mountains and a long season is thereby insured to workers in the placer camps. The Raven placers, near the Gold Coin mine, have been leased to LaFayette Brown.—W. E. King has just completed a 10-stamp mill on his property in Rye valley which will go into commission at once.—Capt. Case has concluded a test, in Denver, of a carload of ore from the Tabor Fraction mine, above Sumpter, and the character of reduction plant, for that property, has been determined.—In Quartzburg district, the Standard, which produces cobalt, is putting in a concentrating mill, with a capacity 50 tons per day.—The Copperopolis, W. W. Gibbs, superintendent, is erecting a 150 ton concentrator.—Frank J. Davey, engineer-in-charge, is cyaniding 100 tons gold ore daily, from a surface deposit below the old Virtue mine.

Baker City, April 26.

JOSEPHINE COUNTY.

The Eureka mine, on Soldier creek, is reported sold to Pittsburg parties, the first cash payment being $30,000. Much tunnel work had been done, and $250,000 worth of ore has been blocked out. The mine was discovered ten years ago by William H. Miller who took out $15,000, which he mortared out.

SOUTH CAROLINA.

The Southern Kaolin & Aluminum Co. at Blaney, has been incorporated to operate a kaolin mining plant at Rolling's mill. The company will, for the present, confine its operations to mining and shipping kaolin and manufacturing caustic soda, expecting soon to equip a plant for the manufacture of aluminum. Officers of the company are E. O. DePass, president and treasurer; W. S. Leib of Philadelphia, secretary.

SOUTH DAKOTA.

CUSTER COUNTY.

The New York mica mine, at Four Mile, six miles west of Custer City, has been sold to F. N. Meyer, representing the Westinghouse Electric & Manufacturing Co., of Pittsburg. Work is to be resumed at the mine and a plant is to be erected, either there or in town, for trimming, grinding, and otherwise preparing the mica for market. This mine has the largest mica-bearing dike in the Black Hills.

The Gertie Tin Mining Co., at Hill City, has been running the mill for some time, and recently the company erected a small smelter to reduce the mineral. The first test has been made, resulting in a quantity of pig tin, and the company expects to continue smelting. The Gertie controls 155 acres of land near Hill City and development work has exposed a large amount of ore. The property is under the supervision of M. L. Moyer, of Cleveland. Tests are being made in Denver on ore from the Ivanhoe mine, six miles east of Custer. This ore has proved difficult to treat, but it is thought that the present investigation will result in a solution of the difficulty.

UTAH.

SALT LAKE COUNTY.

The Utah Copper Co. has placed an order for three mine locomotives, and also an order for 50 ore cars of 12-ton capacity. The equipment is to be used underground.

VIRGINIA.

The Rye Valley Lead Mines Co. has been reorganized for the purpose of continuing the operation of lead mines in Rye Valley, near Sugar Grove. It is the intention of the company, of which H. H. Green is manager, to install a 100-ton concentrating plant.

WASHINGTON.

FERRY COUNTY.

The Pearl Consolidated mine shows improvement in the Lone Pine workings, and if railway cars could be had ore shipments could reach 1000 tons this month. S. P. Domer, general manager of the Ben Hur mine, reports that ten to twelve carloads of ore have been the average monthly shipment for some time, and

the ore has shown a steady improvement, owing to the small rich streaks of silver sulphuret and iron sulphide with native gold which run through it. From ore shipped in April, more than all of the expenses were paid from three carloads, and from five carloads from the winze, now at the smelter, the returns are expected to run better than from any ore ever shipped from this mine. The winze from the 300-ft. level is down 50 ft. where the vein is five feet wide. The winze is ten feet from the shaft, and work on the latter will be resumed.

A shaft on the Hidden Wealth, in the Iron Mountain section of this district, was sunk fifteen feet on a 52-inch vein, with six inches of talc on foot and hanging. The ore is reported to assay $25 per ton, including 5.4% copper. Work will be resumed on the tunnel, which will be driven 50 ft. further to tap the vein 150 ft. deep.

OKANOGAN COUNTY.

A shaft has been started on the Copper World, on Palmer mountain, and the company will sink it to 500 ft. John Wentworth is superintendent.

Peter Berg, of San Jose, Cal., has brought suit in the Superior court, to quiet title, against the Lone Pine Group Gold-Silver Mining Co. He claims a part of the Lone Pine ground, and the mine has been closed to await decision of the court.

STEVENS COUNTY.

Shipment of ore from the Napoleon mine, east of Kettle river, has been suspended owing to the bridge at Orient being carried away by high water. There will be no effort to resume shipping until the aerial tramway has been installed. The ore shipments from the First Thought mine to the Granby smelter, at Grand Forks, B. C., have averaged 30 tons a day during the past month.

The contract for driving the last 100 ft. of a tunnel on the Orient group has been finished, and another will be let immediately.

BRITISH COLUMBIA.

YALE DISTRICT.

The four-compartment shaft at the Mother Lode mine is nearing the 400-ft. level. Drifting to connect with the winze from the north drift, which reached the 400-ft. level some time ago, will be commenced as soon as the shaft reaches the 400. The Mother Lode diamond-drill has been in operation on Primrose ground (to the south of the main shaft), where a hole 200 ft. deep has been bored, showing considerable ore. The last shipment of Strathmore ore maintained the past record of this mine, and strengthens the belief that it will become one of the paying mines of Greenwood. Returns show the first class went $151 per ton, and second class $82 per ton.

Surveys are being made and right of way secured for the extension of the new high-tension electric line from Greenwood to the Mother Lode mine of the British Columbia Copper Co. and the Boundary Falls smelter of the Dominion Copper Co., each being four miles from Greenwood. The work is being done by the British Columbia Constructing & Distributing Co., a subsidiary company of the West Kootenay Power & Light Co. At Greenwood and Grand Forks work is under way on the sub-stations for the company, where the power, which will be brought over the mountains from Bonnington falls on Kootenay river at 60,000 volts, will be transformed to about 2,000 volts for commercial purposes. The new sub-stations are to be replicas of those at Phoenix, which, finished and furnished, cost the company $40,000.

The Provincial road supervisor, E. E. Spragett, will leave the first of the week for the upper North Fork district to complete the building of six miles of wagon road to the McKinley mine and properties. The government recently set apart $3,750 for the building of this piece of wagon road, which will, when completed, give access to the principal properties of Franklin camp.

Work has been pushed on the excavations necessary for enlargement of the smelting works of the British Columbia Copper Co. at Greenwood. The old works will be practically rebuilt on modern plans, the machinery now being manufactured in the East, and some of it will be shipped soon. As a consequence of remodeling and enlarging the plant, it will be necessary to close the works for possibly two or three months, while the new machinery and buildings are being erected. In the meantime, shipments of ore will be discontinued at the company's Mother Lode mine in Deadwood camp, and the entire force placed on development, preparing for the larger output that will be required at the smelter when the enlargements are completed. The mine will, in the meantime, be equipped so that the machinery may be driven by electricity instead of with steam, as at present. When in running order again the smelter is expected to be able to treat about 50,000 tons of ore monthly, as against 18,000 tons, the present capacity. A strike has been made on the Gloucester property in Gloucester camp. T. Newby, with a force of miners, encountered a vein of high-grade chalcopyrite seven feet wide and traceable for over 250 ft. G. A. McLeod is at the mine, with Louis Noble of Denver. A. D. McPhee, superintendent of the McKinley mine, has gone from Phoenix to that property. Eight men are working at the McKinley and this force will be increased as soon as the roads permit hauling of mining machinery.

The Tyee Copper Co.'s smelter at Duncan's station, Vancouver Island, ran 13 days during April, and treated 1717 tons of Tyee ore, giving a return after deduction of freight and refining charges of $34,723.

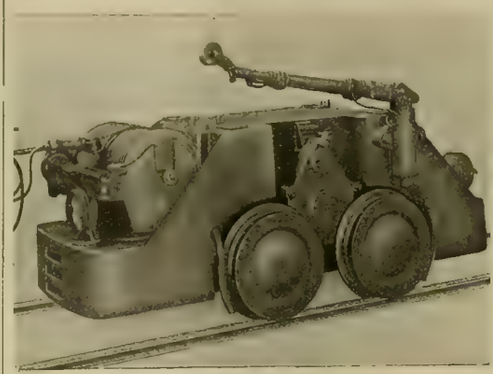
MEXICO.

DURANGO.

A consolidation of the Vacas Mining & Milling Co. with the Quebradilla Mining Co., has been effected, the properties of both concerns passing into the hands of a new company, the Vacas Mining Co. The Vacas mine has a large new Lidgerwood hoist and two boilers installed; the old concentrator was overhauled and many additions made to the machinery, all of which was in operation at the time of the transfer. The addition of other mines, giving larger ore resources, requires further increase of the mill capacity, already under way. Other enterprises in the vicinity are active, being encouraged by the expected extension of the railroad from Durango to Sombrerete, among which are the silver mines at La Novia, for the operation of which there is talk of a large electric power-plant.

JALISCO.

Approximately $35,000 gold will be spent by the San Pablo Mining Co. in the development of the San Pablo mines in Etzatlan district, which were recently purchased from W. M. Mathews. The plans call for a main tunnel and crosscuts aggregating 1,100 m., estimated to cost $22,500. The installation of the compressor and drill-plant, which have been ordered, will cost $7,500. W. M. Mathews, former owner of the mines, shipped 363 tons of ore from the San Pedro vein which netted him $13,159. Some of the ore shipped ran eight and one-half kilograms silver and 455 grams gold per ton. It is estimated that the ore can be mined and milled at a cost of $6 per ton.



NEW GOODMAN "M S 2" GATHERING LOCOMOTIVE.

Robert Scott, of San Jose, Cal., inventor of the Scott fine-ore furnace, is building a furnace for T. W. Lawson, of Boston, who owns extensive deposits in the Mascota district. The development of the cinnabar deposits has been in progress during the last two years.

Machinery for a reduction plant at the mines of the Aztec Copper Smelting Co., in the Guachinango district, has been shipped from the United States. The machinery consists of a rock-breaker, two mills and six concentrating tables, the plant having a capacity of 80 tons daily. The development work now in progress consists of a tunnel to cut the veins of the Concha and Perla mines, the first at a depth of 115 ft., and the second at 407 ft. The tunnel is designed to go 1,000 ft., and it is now in 175 ft. A wagon road has been completed from Ameca to the mines, a distance of 25 miles. George J. Graham is general manager of the Aztec Copper Smelting Company.

A company is being organized in New York by American and European capitalists to operate the Cuale mines, in the municipality of Talpa de Allende. A ten-year concession has been granted to this company, and includes 20 old Spanish mines, which have all been good gold, silver, copper and lead producers. It is said that there are thousands of tons of ore on the dump that can be milled at profit. The nearest point for shipment is at Penas, a port on the bay of Banderas, 40 km. distant. There is plenty of good timber, fir, pine, and oak on the properties, and an abundance of water for power.

SONORA.

The Ronquillo Mining Co. is developing a tract of 72 pertenencias, 18 miles south of Cananea. In drifts at 100-ft. depth, there is said to be a good showing of copper ore. The mines are in the Manzanal range, where a number of properties are being opened. The company also owns a small tract known as Swansea, lying to the east of the Cananea Consolidated Copper Co.'s Cobre Grande mine and north of the American property, where developments are also to be inaugurated. Thirty-six Wilfley tables and 72 Frue vanners are being added to the concentrators of the Cananea plant, the capacity of which will thereby be increased 1,000 tons daily. The mills are now handling 2,400 tons daily. At the smelter, reverberatories of the Anaconda type are being put in, while larger hoisting plants are to be installed at several shafts. The production of the Greene Consolidated Copper Co. for the month of March was 5,100,000 lb., compared with 5,000,000 lb. in February, and 5,100,000 lb. in January. The output of April will exhibit an increase, as the new reverberatory furnaces were placed in operation the first of that month.

A Real Gathering Locomotive.

The common tendency heretofore in the development of electric mining locomotives for use in gathering service has been to adapt standard designs, principally by addition of a cable reel. Efforts in this direction have involved use of the standard two-motor type of locomotive, having heavy side frames and fitted with two independent motors carried on the axles. This type of locomotive cannot be built sufficiently compact to fulfill properly the usual requirements of gathering work. For narrow gauges, the frame must be outside the wheels. Furthermore, the over-all length is necessarily excessive, because of the consturction required for accommodation of two motors. Other matters, including length of wheel base, general over-all dimensions, flexibility for operation over poor tracks, etc., combine to render difficult, if not thoroughly impracticable, the satisfactory adaptation of a standard type of locomotive to the conditions of gathering service.

In taking up this problem, the Goodman Manufacturing Co. has treated it as properly a subject of special design, recognizing the peculiar character of the work as distinctly different from regular haulage service. The accompanying illustration shows the new Goodman M.S.2 gathering locomotive, the design of which was dictated by careful analysis of the conditions to be met. As a principal requirement there has been recognized the necessity that a really efficient gathering locomotive must be of such size and weight as will enable it to go wherever a mine-car can go, and with equal facility. This requirement has been kept in mind throughout the design. The cable reel, by means of which the locomotive is enabled to run into rooms and other parts of the mine where the trolley wires are not extended, is a separate piece of mechanism, operating independently of the locomotive gearing. This feature of separate operation for locomotive and reel is of great importance.

As regards the locomotive, it should be noted that the wheel-base is very short and that the wheels themselves are small. Only one motor is used and this is built in as a unit with the locomotive frame. The axles are fitted with springs so as to afford a flexible wheel-base which will enable the locomotive to follow a rough track even more easily than will the mine-car itself. By gearing of special design and arrangement the armature of this single motor, built into the frame, is in driving connection with both axles, yet without interesting with the flexibility of wheel-base. This design and arrangement of a single motor geared to both axles enables extreme compactness, as is especially desirable in the matter of over-all length or of distance from center of drawbar pin at either end. The value of this characteristic will be appreciated in consideration of the necessity that such a gathering locomotive shall haul a mine-car, with short hitch, around room-neck curves of small radius.

The height of the locomotive from rails to top of frame is 32½ in., and the over-all length is 7 ft. 9 in. All operating devices are placed conveniently within easy reach of the motorman. The brake is worthy of note, being very powerful and providing accurate and close control, inasmuch as the brake-band is applied to a high-speed surface and is operated by a lever-handle with ratchet-latch. This machine is no larger than the average mine car, yet is extremely strong and of very simple design. It marks an essential departure in that it recognizes the special character of gathering service.

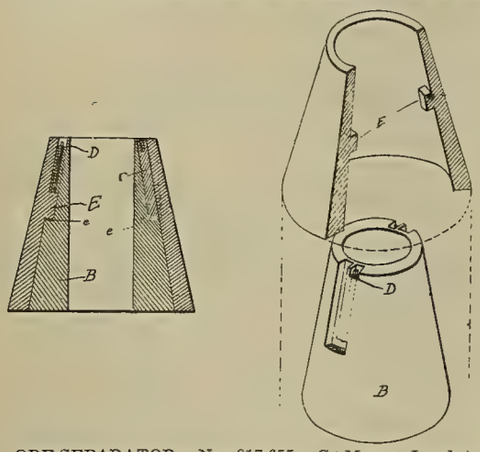
Mining and Metallurgical Patents.

Patents issued April 10, 1906.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

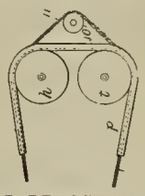
ROCK AND ORE BREAKING MACHINE. No. 817,672. E. H. Sansom, Goodwick, England.

A device of the character described comprising a cone having recesses in its face, a mantle fitting over said cone, lugs on the mantle adjustably fitting in the recesses of the cone, bolts passing through the cone and bearing against the lugs of the mantle to hold said mantle in its adjusted positions and locking-pins to hold the mantles, said locking-pins having recesses in their ends.



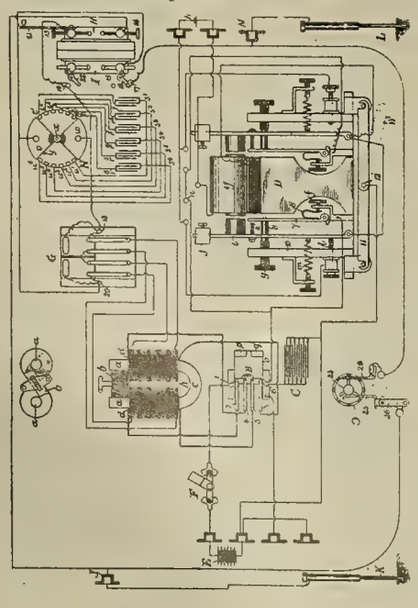
ORE-SEPARATOR. No. 817,655. G. Moore, London, England.

In an ore-separator, the combination of a traveling endless belt provided with side flanges, pulleys over which said belt runs, operating means for said belt, a second belt lying within said first-named belt and between the flanges thereof, said second belt being composed of two layers, the under layer being a wire screen and the upper layer being burlap, and an idler-pulley over which said second belt runs to separate it for an interval from said first-named belt.



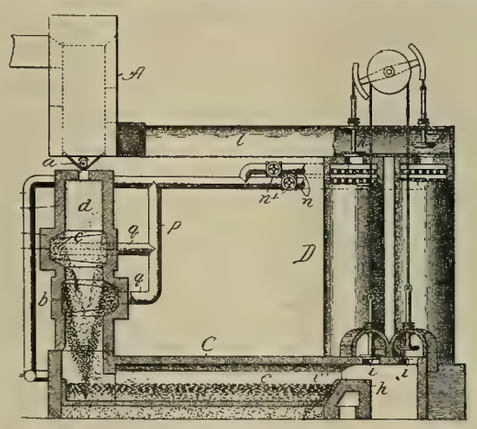
APPARATUS FOR DETECTING AND LOCALIZING MINERAL DEPOSITS. No. 817,736. L. Daft, Ealing and A. Williams, Wimbledon, England.

An apparatus for locating mineral deposits consisting of a combination of a source of electricity, an indicator which is adapted to emit fluctuating electric impulses, two portable electrodes which are electrically connected, having the battery and inductor in series between them, two other portable electrodes which are electrically connected and a resonator which is in series between them, such resonator being adapted to produce audible sensations from electric impulses.



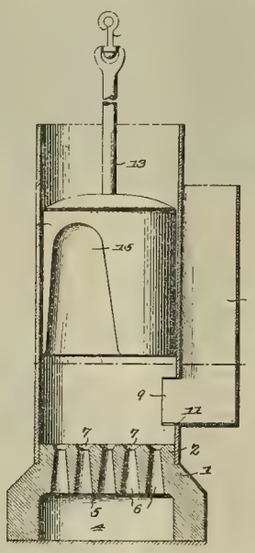
PROCESS OF REDUCING ORES. No. 817,414. H. F. Brown, Chicago, Ill.

The process of treating a finely-divided mixture of metallic oxides and slag-making impurities, which consists in subjecting the material while in atmospheric suspension to the action of a reducing-gas moving in the same direction, and during such subjection bringing the particles of the mixture into approximate physical contact, then causing the reduced material to pass without subjection to an oxidizing influence into a molten slag-covered bath, and at the same time causing the reducing-gas to mix over the surface of the bath with an excess of oxygen to further its combustion and heat the bath, then permitting separation by gravity of the metal from the slag-making impurities while protected by the said slag covering from the oxidizing atmosphere.



ROCK-CRUSHER. No. 817,298. J. Y. Byers and J. W. Myer, San Diego, Cal.

In a machine of the class described, the combination with a die provided with cone-shaped escape-openings having their upper ends countersunk, of a mortar having a feed-chute in its side, and a pestle arranged within the mortar and provided on one side with a pocket all the walls of which are curved.

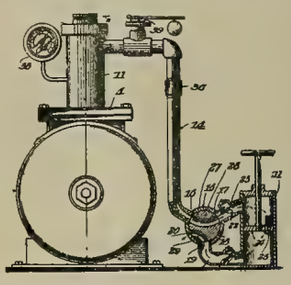


DRILL-ROD COUPLING. No. 817,398. V. G. Smith, Iola, Kans.

In a rod-coupling, a rod having at one end a recess tapered for the greater portion of its length and provided with an internal thread, said rod being further provided with a radially-disposed set-screw-receiving opening and having at its periphery a recess surrounding the wall of the opening, the wall of said recess being provided with a plurality of notches, a second drill-rod section having a threaded stem tapered for the greater portion of its length and provided near its extreme inner end with an annular groove, a set-screw extending through the radial opening and entering said groove, the head of the set-screw having a diametrical opening, and a cotter-pin arranged in said diametrical opening and movable in the direction of its length to introduce one of its ends into locking engagement with any one of the notches, the pin when free from the notches having unrestricted revoluble movement to permit adjustment of the set-screw.

ELECTRIC FURNACE. No. 817,212. C. O. Wingren, Pasadena, Cal.

The combination of a metallic air-tight casing composed of a body portion and a removable cover secured thereto, said cover being provided with an upwardly-extending dome, a portion of the top of said dome being transparent; electrodes insulated from and secured to said body; resistance material in said casing between said electrodes; a crucible in said resistance material between said electrodes; a heat-insulating material within said casing and surrounding said electrodes and crucible except at and near the dome; a viewing-pipe extending from the crucible upwardly through the heat-insulating material and terminating near the dome; and air-exhaust mechanism connected to said dome whereby the air may be exhausted from the crucible.

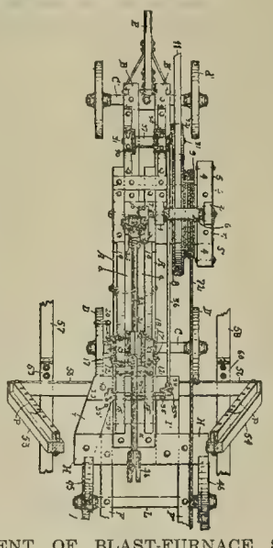


PROCESS OF TREATING ORES OF THE PRECIOUS METALS. No. 817,411. A. C. Atwater, Manchester, Iowa.

Process for extracting metals from their respective ores containing selenium, by volatilization, consisting in mixing the ores in granulated form with a theoretical proportion of carbonaceous material, say from one (1) to ten (10) per cent., according to the nature of the ore being treated, heating the materials so mixed while protected from the air, to a temperature sufficient to volatilize the selenium, which may be present and eliminating it in the form of vapor, thereby separating such element from the precious metals, after which allowing it to cool while the air is still excluded.

WELL-DRILLING MACHINE. No. 817,527. J. W. Shawver, Portland, Ind.

In a well-drilling machine having in combination, two main frame-sections, ground-wheels on which the said main frame-sections are mounted, an axle for each pair of ground-wheels, the forward section having a walking-beam mounted thereon, the frame of said front section being formed of a pair of main sills spaced apart and extending to the rear beyond rear wheels of said front section and forwardly terminating in the rear of the front wheels thereof, auxiliary sills extending from the sides of the main sills forward and being pivotally mounted to the axle of the front wheels, a derrick extending over and above the sections, means for securing the derrick in position, and means for raising and lowering the derrick by power transmitted through the mechanisms located on the machine.



TREATMENT OF BLAST-FURNACE SLAG FOR PRODUCTION OF MATERIAL SIMILAR TO TRASS, ETC. No. 817,158. H. Colloseus, Berlin, Germany.

The process of manufacturing trass-like material from blast-furnace slag, which consists in introducing into the stream of molten liquid slag small amounts of chemically-inactive liquid successively in quantities sufficient for immediate evaporation of the liquid in contact with the hot molten material.

Personal.

H. Kilburn Scott writes from Cape Town.

Frank Nicholls is on his way from London to Siam.

F. H. Minard has returned to Denver, from Mexico.

Fred G. Farish is examining mines near Hailey, Idaho.

W. A. Prichard now makes headquarters in Mexico City.

Alfred James is on his way from Australia to San Francisco.

R. Gilman Brown is making a visit of inspection at Ymir, B. C.

Alan J. Fairbairn has returned to Breckenridge, Colo. from London.

George E. Moulthrop is general superintendent for the Red Metal Co., at Butte.

F. M. Simonds and E. Z. Burns, of New York, are in Mexico on professional business.

Arthur C. Carson has been appointed general manager of the Butte Coalition Co., at Butte.

J. V. N. Dorr, of the Black Hills, has returned from a visit to Salt Lake City and Denver.

M. C. Russell, of Lake City, Minn., is at Half Moon Pass, Sunny Mt., Fergus county, Montana.

Wilbur E. Sanders, of Helena, Mont., is investigating mines in Washington and British Columbia.

Rensselaer H. Toll, of Mancos, Colo., is in Cripple Creek this week examining mining property.

Wilbur E. Sanders, of Helena, Mont., is investigating mines in Washington and British Columbia.

Lewis T. Wright, manager of the Mountain Copper Co., has returned from a hurried visit to New York.

E. M. Ray, manager of large mining properties in Chihuahua, Mexico, is in Denver, Colo., for a few days.

John B. Farish, who was in San Francisco during the earthquake-fire, is on his way from Denver to New York

H. G. Murray leaves San Francisco on May 25 for Java, to take charge of mining operations for an English company.

W. W. Barton, manager of the Gt. Boulder Main Reef mine in Western Australia, has resigned and is expected in Mexico.

H. DeC. Richards, whose address is still at the Cosmos Club, San Francisco, has gone to New York on a brief visit.

Edgar Collins, manager of the Combination Mines, Ltd., at Goldfield, Nevada, has been on a visit to Santa Cruz, California.

Reginald W. Petre, of Baltimore, has been appointed manager of the Colonial Copper Co.'s mines at Cape D'Or, Cumberland county, Nova Scotia.

Edward H. Nutter passed through Berkeley on his way to Telluride, Colo., where he will be assistant superintendent of the Liberty Bell mine.

Guy Sharwood, a student of the University of California, has gone to the Homestake mine, at Lead, South Dakota, to join his brother, W. J. Sharwood.

E. H. Nutter has resigned the superintendency of the Standard Consolidated mine at Bodie, Cal., and has gone to the Liberty Bell mine near Telluride, Colorado.

Donald R. Morgan has resigned as superintendent of the mining department of Cia. Metalurgica de Torreon, S. P., and will assume the duties of consulting engineer with the same company.

F. H. Mason, who until lately carried on a consulting mining and metallurgical business at Halifax, Nova Scotia, has sold the goodwill of the same to A. L. McCallum, late of the Dominion Steel Co. Mr. Mason proposes to reside in California in future. He is now at Johnsville, Plumas county, California.

Books Received.

High-Tension Power Transmission, Vol. II, is a series of papers and discussions presented at the International Electrical Congress in St. Louis, and presents in convenient form the present state of knowledge of the transmission of power by electricity. Much space is devoted to the various types of line construction, particularly as to details. Each of the several papers has been written by men who are in daily contact with the actual business of designing, constructing, and operating electric transmission plants. As a book of reference it is superior, and one which will well repay careful study. This book will be sent upon application to the Mining and Scientific Press. Price $2.50. Published by the McGraw Publishing Company, 114 Liberty St., New York.

Electric Transmission of Water Power, is a late contribution to this important subject, by Alton D. Adams. The work systematically takes up the various problems connected with the transmission of electrical energy, developed by water power, including the location and development of water powers, the limitations of electrical transmission, advantages of alternating and continuous current, locations of power stations, line equipment, materials, and construction details. The work is handsomely and profusely illustrated, including several maps showing important electric installations. To electrical engineers and students this will be a valuable book, both for study and reference. Sent by the Mining and Scientific Press upon receipt of price, $3. McGraw Publishing Company, 114 Liberty St., New York.

Notes on Electrochemistry, by F. G. Wiechmann, has the distinction of being something new in this line. It has been the aim of the author to meet the requirements of the student of the interesting science of electrochemistry, the chief object being the supplying of suitable notes to students entering on the study of the subject, saving much laborious research in larger volumes. While this book contains much found in other and larger volumes, it has systematically arranged the matter so as to make it a convenient introduction to the study of electrochemistry. Sent by the Mining and Scientific Press upon the receipt of price, $2. McGraw Publishing Company, 114 Liberty St., New York.

Temporary Addresses of San Francisco Firms and Professional Men.

ADAMS, W. J., 2205 Bush St., San Francisco.

ALLIS-CHALMERS CO., 906 Broadway, Oakland.

AMERICAN TOOL WORKS, 4153 20th St., San Francisco.

ASBESTOS MFG. & SUPPLY CO., 1834 Ashby Ave., Berkeley.

Trade Treatises.

The Crocker-Wheeler Co. announce Bulletin 64, which describes Form 1, Motors and Generators.

The Colorado Iron Works Co. of Denver, Colo., has issued an interesting pamphlet, Catalogue No. 9A, descriptive of their Impact Screen, which is designed to screen ores either wet or dry.

The Wellman-Seaver-Morgan Co. of Cleveland, Ohio, have issued a handsome circular, descriptive of their electric hoists, in which the several types of electric winding engines made by them are fully described and illustrated.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 10 Bacon Block, Oakland, has official reports of the following United States patents issued to Pacific Coast inventors:

819,196—SLEEPING CAR—T. O. Abbott, Seattle, Wash.
819,114.—SAW SET—G. Y. Anderson, Seattle, Wash.
819,629.—REGULATOR FOR WATER WHEELS—G. H. Bailey, San Francisco, Calif.
819,686.—SAFETY DEVICE FOR FOLDING BEDS—S. B. Bankson, San Francisco, Calif.
819,204.—CHICKEN ROOST—G. H. Buckingham, Los Angeles, Cal.
819,700.—FURNACE—A. C. Calkins, Los Angeles, Cal.
819,636.—SUBMARINE DRAG-BUCKET—E. J. Condlon Ballard, Wash.
819,691.—DUMPING VESSEL—P. Constantine, Seattle. Wash.
819,042.—UNDERREAMER FOR MINERAL BORING—A. Cummings, Los Angeles, Cal.
819,342.—SOLAR WATER HEATER—M. T. Cunniff, Riverside, Cal.
819,211.—VAPOR GENERATOR—R. F. Driscoll, San Francisco, Cal.
819,529.—VULCANIZED MATERIAL—F. Ephraim, San Francisco, Cal.
819,540.—PROPELLER—F. C. Gordon, Asotin, Wash.
819,698.—SEAM-IRONING MACHINE—Hall & Martin, Oakland, Cal.
819,217.—OIL CAN—C. R. Harless, Dayton, Wash.
819,426.—HEALER & DUPLEX BURNER—C. R. Harris, Los Angeles, Cal.
819,277.—BRAKING APPARATUS—W. L. Holman, San Francisco, Cal.
819,282.—MEANS FOR PROTECTING PILES—A. M. Hunt, Berkeley, Cal.
819,660.—GAS WASHER—L. P. Lowe, San Francisco.
819,661.—MANUFACTURING GAS—L. P. Lowe, San Francisco, Cal.
819,662.—GAS-MAKING APPARATUS—L. P. Lowe, San Francisco, Cal.
819,663.—COKING & MAKING GAS—L. P. Lowe, San Francisco, Cal.
819,664.—APPARATUS FOR SEPARATING RESIDUE FROM LIQUIDS—L. P. Lowe, San Francisco, Cal.
819,665.—GAS HOLDER—L. P. Lowe, San Francisco, Cal.
819,666.—APPARATUS FOR GENERATING GAS—L. P. LOWE, San Francisco, Cal.
819,295.—PUMP MECHANISM—S. W. Luitwieler, Los Angeles, Cal.
819,239.—MIXING & COMBINING DEVICE FOR GAS ENGINE—L. J. Marks, San Francisco, Cal.
819,576.—SLING FOR HOISTING APPARATUS—W. L. McCabe, Seattle, Wash.
819,074.—GAS GENERATING MACHINE—O. V. Monroe, Portland, Ore.
819,575.—BAKING APPARATUS—G. A. Muller, San Francisco, Cal.
819,306.—BALLOT MEMBER FOR VOTE REGISTERING MACHINES—D. L. Newcomb, San Diego, Cal.
819,583.—AUTO. DOOR OPENER & CLOSER—K. Nishimoto, San Francisco, Cal.
819,379.—CANDLE LAMP—W. J. Rogers, San Jose, Ca'
819,463.—DRAFT-EQUALIZER—H. C. Scott, Ritzville, Wash.
819,317.—SUBMARINE OBSERVATION TOWER—J. E Shrewsbury, Longbeach, Cal.
819,677.—ELECTRIC BLOCK SIGNAL SYSTEM—P. J Simmon, Chico, Cal.
819,384.—APPARATUS FOR TRUING GRINDING DISKS—G. A. Stansbury, Los Angeles, Cal.
819,182.—FRICTION GRAINING MACHINE—Taylor & Flint, San Francisco, Cal.
819,386—SHOCK ABSORBER—H. C. Turner, Los Angeles, Cal.
819,387.—PNEUMATIC TIRE—C. R. Twichell, Los Angeles, Cal.
819,621.—PAVER PUNCH & SHEARS—L. Van Dorin San Bernardino, Cal.
819,679.—AUTO. COMPUTING CHEESE CUTTER—F. F. Wear, San Francisco, Cal.
819,394.—ADVERTISING DEVICE—H. S. Williams, Los Angeles, Cal.
819,328.—PIANO ACTION—J. L. Wilson, Los Angeles Cal.
819,490.—NONREFILLABLE BOTTLE—E. K. Wood, San Francisco, Cal.
819,195.—ELECTRIC ELEVATOR—P. Wright, Los Angeles, Cal.
819,112.—DISH CLEANING APPARATUS—R. Wylie Napa, Cal.
37,980.—(DESIGN) SCRAPER—E. R. Deming, Alameda, Cal.

Commercial Paragraphs.

The C. A. Luckhardt Co., of The Nevada Metallurgical Works, are prepared to resume their usual business at 810 Broadway, Oakland, California.

The Westinghouse Electric & Mfg. Co., within the last week or two, have received orders for 55 electric locomotives, some of which are for mining work.

The Broderick & Bascom Rope Co., of St. Louis, have just published a comprehensive price list marked 'G' which is considerably larger than the last one published. This will be sent to anyone interested.

Fairbanks, Morse & Co., Chicago, report the sale of a large number of their standard mine cars to the Republic Iron & Steel Co., Nassau Ore Co., La Rue Mining Co. and the Rhodes Mining Co., for use in these companies' large iron mines in Minnesota.

The Western Gas Engine Co., Los Angeles, builders of engines and hoists, have opened branches in Oakland and San Francisco. J. F. Willard, formerly manager for Beck, Wakefield & Co., is in charge. They are located at Third and Washington streets, Oakland, and 547 Fulton St., San Francisco.

The De La Vergne Machine Co., New York, reports having recently closed the following contracts for Hornsby-Akroyd oil-engines: Windsor Locks Water Co., Conn., 50 h.p.; John McKesson, Chappaqua, N. Y., 9 h.p.; Bergstrom & Bass, Brooklyn, N. Y., 20 h.p.; S. Oppenheimer & Co., New York, 25 h.p.; Freeman, Daughaday & Co., Chartley, Mass., 50 h.p.; Township of West Lebanon, Pa., 44 h.p., for pumping station; Borst & Rockstroh, Middleburg, N. Y., 7 h.p.; The John Prikl Iron Works, Brooklyn, N. Y., 50 h.p.; John W. Sullivan, New York, 75 h.p.; F. A. C. Perrine, New York, 7 h.p; Houston Ice & Brewing Co, Houston, Tex., 16 h.p.

Wm. Clegg, Jr., who has been special agent of the Westinghouse Electric & Mfg. Co. in their St. Louis territory, has been appointed acting manager of the St. Louis office. D. E. Webster, formerly manager of the office, has been transferred to a position in the Chicago sales office of the company. J. S. Tritle has been appointed acting manager of the new district office opened by the company in room 512, New England building, Kansas City, Mo.

7-USEFUL BOOKS-7

BY T. A. RICKARD

EDITOR OF THE MINING AND SCIENTIFIC PRESS

THE STAMP-MILLING OF GOLD ORES.....$2.50
A general treatise on the practice of the stamp-mill in America, Australia and New Zealand.

THE COPPER MINES OF LAKE SUPERIOR.....$1.00
An attractive book describing the famous mines of the Keweenaw peninsula, with observations on the methods employed in the mills and underground.

ACROSS THE SAN JUAN MOUNTAINS.....$1.00
An account of a 400-mile ride across the most interesting mining regions of Colorado.

THE SAMPLING AND ESTIMATION OF ORE IN A MINE..$2.00
This describes an important branch of mining engineering, and is based upon many years of actual practice in the examination of mines. The value of the book is enhanced by a discussion to which many distinguished engineesrs contributed.

PYRITE SMELTING. Edited by T. A. Rickard.....$2.00
Discussion and comment on the treatment of sulphide ores in the blast furnace without carbonaceous fuel, with contributions by the leading metallurgists of America.

ORE DEPOSITS—A DISCUSSION. Edited by T. A. Rickard $1.00
With contributions by S. F. Emmons, W. H. Weed, J. E. Spurr, W. Lindgren, J. F. Kemp, F. L. Ransome, C. R. Van Hise, and C. W. Purington.

ECONOMICS OF MINING. Edited by T. A. Rickard.....$2.00
Discussion and comments by experienced mining engineers. The book deals with mine valuation, costs, ratio of equipment to ore reserves, and other allied subjects.

These Books Can Be Purchased at Any of the Offices of the Mining and Scientific Press

EDITORIAL.

MILLMEN and metallurgists will thank Mr. Charles Butters for his practical notes on the operation of tube-mills at El Oro. The practice is so new that the literature of the subject is scant, and it is not often that so busy a man can be persuaded to take his pen in hand. Our friends at El Oro will receive Mr Butters' suggestions with interest, and we trust that they may be able to add to the information which we take pleasure in publishing. We are informed by Mr. Charles Rhodes, manager of the Waihi mine, that the service given by the tubes has proved so satisfactory, that shortly there will be a dozen of them at work at this, the premier gold mine of Australasia.

OUR CORRESPONDENT at Toronto has had much that is interesting to say recently concerning the Cobalt mining excitement in northeastern Ontario, Canada. We note that one mining company, the Nipissing, has issued its annual report, according to which the net profits to May 1 have been $1,021,628, giving $400,000 to the shareholders and leaving a surplus of over $600,000. The ore all came from near the surface, the deepest shaft at Cobalt having reached only 230 feet. The ores are valuable chiefly for native silver, together with nickel and cobalt minerals. In many ways, in its mineralogy and ore occurrence, Cobalt resembles the mines of the Chalanches, near Allemont, in southeastern France.

ON ANOTHER PAGE we publish part of an address delivered by Mr. John C. Branner of Stanford University. Professor Branner needs no introduction to our readers. The address we refer to was intended as a popular explanation of certain scientific observations, and we confess that when a first-rate man of science takes off his coat—of conventional phraseology and rather overburdened terminology—in order to explain things to the lay mind, although in common with our readers possessing the rudiments of a scientific training, we enjoy it. Huxley's addresses to workingmen still stand as the ideal of scientific lectures. They were listened to with equal interest and profit by Prime Ministers and carpenters. This is a time when geologists are not without honor in their own precinct; we hope they will utilize the opportunity to enlighten the popular mind on matters that recent events have proved to possess a vital interest.

THE ANNUAL REPORT of the Anaconda Copper Mining Company, given elsewhere in this issue, is interesting. It appears that, finding it impracticable to modernize the old reduction works, the new smelter of the Washoe Copper Company (of the Amalgamated) was leased, and thereby a saving of $2,583,549 was effected on the treatment of 1,626,306 tons of ore and slag, equivalent to $1.5886 per ton, as compared to the old works. The report speaks of "modernizing" the old plant, and the use of the word is suggestive. When you modernize a copper plant, you adopt the improvements introduced not during the past century, but in the last ten or fifteen years. At the mines, the explorations at the bottom have been most encouraging, rich ore being found at 2,400 feet. This means much to Butte and signifies a good deal to the geologist, for it has proved that secondary enrichment, by deposition of chalcocite, can, under rare conditions, extend to a great depth. The profits for the year represent 19.06 per cent on the $30,000,000 capital of the company. By reason of the increase in the price of copper, which is 2½ cents higher than the average of 1905, the Aanaconda Copper Company should make a handsome showing during 1906. Whatever it may be, it is likely to be discounted far in advance by the stock market.

THE DIFFICULTY of classifying tracts of land claimed by railroads to be agricultural, and, therefore, within the terms of their grants, has been lessened lately by co-operation between the General Land office and the Geological Survey, whereby experts from the latter department have given their opinions conclusively on the question in dispute. As a rule the testimony in such cases is of the most obviously worthless kind, being rarely free from influence, but this utilization of the special knowledge of a scientific bureau will secure the evidence of witnesses who are not advocates. A case in point occurred recently when the Government took steps to investigate the real character of a tract covering thirty townships in Idaho which had been claimed by the Northern Pacific Railroad to consist of agricultural land. In rebuttal of the railroad company's case, the Secretary of the Interior caused an examination to be made by one of the geologists of the Survey, and his testimony, supporting the classification of the tract as mineral land, won the case. We believe that the officers of the Survey would testify against the Government interest should the geological data indicate the non-mineral character of a disputed tract, in short, that they give the facts as they find them—the only sort of testimony compatible with the spirit that actuates scientific enquiry. The railroad companies are entitled to their legal rights, and if we welcome a decision adverse to them, it is only because there is good reason to believe that, in many instances, they have stretched the meaning of the terms whereby they were granted certain privileges until their grants have served as the instruments of land grabbing, prejudicial to the rights of the community.

Earthquake Sounds.

There is no question as to the fact that earthquakes are audible before they are felt. We noted this on April 18, not in case of the big shock, when our faculties were otherwise engaged, but in connection with several later movements on the same day. Other trustworthy evidence has been secured since. An intelligent lady who had experienced the earthquake of 1868, being awake, at 5 A. M. on April 18, 1906, heard the sound of the oncoming disturbance; it seemed to her like the sound of a mighty rushing wind and knowing what it presaged, she instantly alarmed the inmates of the house. As they escaped outdoors, the tremor came; it shook the earth so that they found it hard to stand and in the meadows close-by the live oaks swung from side to side so as to touch the ground. In the City, several men who happened to be out-doors early on that morning, found it impossible to keep their feet, while a ripple of movement—a sardonic smile—passed over the face of the earth. Others have testified to the noise preceding the arrival of the shock; it varied in intensity according to the distance from the line of actual fracture. This traversed, among other localities, the canyon of Los Gatos, in the Santa Cruz mountains. A trustworthy witness living there, informs us that there was a rumble and a roar like cannonading and that it was "deafening." We also have professional testimony. Mr. John B. Farish, a mining engineer known to our readers, offers valuable evidence on this point. He says: "On the eventful Wednesday morning I was awakened by a loud rumbling noise which might be compared to the mixed sounds of a strong wind rushing through a forest and the breaking of waves against a cliff. In less time than it takes to tell, a concussion, similar to that

caused by the near-by explosion of a huge blast, shook the building (the St. Francis hotel) to its foundations and then began a series of the liveliest motions imaginable, accompanied by a creaking, grinding, rasping sound, followed by tremendous crashes as the cornices of adjoining buildings and chimneys tottered to the ground." The first of these seismic sounds are referable to the rupture of the rock and the subsequent shifting of the broken parts. Sound travels faster in rock than in air. In air the speed is only 1,100 feet per second. It is stated that the earthquake of April 18 was felt at Tokio 11 minutes later than at San Francisco, but this does not mean much until further data indicate at what point the shock originated. It may have been under the Pacific ocean, and in that case the local movement along the old fault-plane in the Santa Cruz mountains would be accessory to a bigger fact. According to good authority, the small earth-waves that make the sounds, travel faster than the big vibrations that cause the shock, the difference in speed being due to the fact that they pass through an imperfectly coherent medium. From the sifting of plentiful data, it was ascertained that the Charleston quake had a velocity of 5,184 meters per second, or 190 miles per minute. The average velocity of the big shocks was 120 miles, while that of the tremors was 180 miles per minute. On the other hand the velocity of sound in granite is 15,000 to 18,000 feet per second, or 170 to 200 miles per minute. This seems to explain why the rumble and roar of a big earthquake precede the shock.

Coal Strikes.

The threatened strike in the Western bituminous coalfields affords food for thought, quite apart from the immediate results of the quarrel between operators and miners.. A thoroughly well informed correspondent at Chicago deals with the subject, under Special Correspondence. in a manner which is well worthy of careful perusal by anyone who desires to see just dealing between employer and employee. In default of a benevolent despot sufficiently powerful and adequately intelligent to discipline the predatory elements of our community, there is nothing except the creation of a strong public opinion to compel justice and fair treatment. One cannot read the description of conditions as given by our correspondent, without realizing how utterly unprincipled are the tactics of both sides, the miners relying on the strength of their organization rather than any right in their cause and therefore breaking contracts in the most callous manner; while the operators appear to be intent on using this opportunity to disregard agreements they themselves had made with the men. and others enacted by the State legislature. Meanwhile, in the anthracite region of Pennsylvania, a dangerous and costly strike has been avoided by concessions made on the part of the mine workers, it being agreed that the awards of the Anthracite Strike Commission of 1903 shall be renewed for three years longer. The retreat of John Mitchell and the other leaders of the United Mine Workers is to their credit, in that their action prevented a great evil to the country and whatever the reasons for it, we accept the fact. There is no doubt but that public opinion was mainly on the side of the operators, whose talk of an 'open shop' deceived many—the anthracite operators constituting the closest monopoly in existence, save Standard Oil. During the two months consumed by the negotiations, the coal companies were able to sell a large part of their stocks of coal at an inflated price. However, the community is to be congratulated on the postponement of further cat-and-dog fights between miners and operators, for three years—long enough to tide over the next presidential election. In the meantime we trust that the Federal authorities will expose the identity of the coal-operators combination and the coal-carrying railroads, so as to stop such predatory industrialism; and though it be too much to hope, we trust the workmen will learn that so long as their demands are just, they can expect the support of public opinion, and that without it they must be powerless, if that which we call civilization is to exist. As for ourselves, we have no more sympathy with the lawless few than the lawless many.

Handling Men.

The subject of the proper manner of managing miners has been discussed recently in this journal by two contributors, both of whom are well-qualified to express opinions. As between the tyrannical foreman who drives his men by sheer power of nerve force, occasionally supplemented by an exhibition of muscular superiority, and the easy-going boss who tries to make things pleasant all round, there is an obvious need of a compromise. Mr. Edward W. Ralph has emphasized the fact that the right man represents the mean between a 'bull-dozer' and the 'good fellow.' It is a problem of practical moment; many a mine has suffered through stupidity in this regard, for men are more than machines, and to get the best service out of them they must be treated neither as coolies nor as mandarins. To our mind the best kind of Cornish foreman represents a desirable type; he is a miner himself, a miner from the ground up, he can do the things he expects others to do, he is physically able to take care of himself in a scuffle, he is good natured and possesses that saving salt, a sense of humor. Many an awkward fellow can be won by a bit of fun at the proper season, especially when backed by other more solid qualities, and good nature will enable a man to shed vituperation which otherwise might lead to a fight. Old Capt. Martin Goldsworthy, in the Michigan copper country, was of this kind. One day when a big Swede had called him all the names not in the dictionary and had finally retired, someone asked the Captain, who was a big powerful man, why he had not knocked him down; he replied, with a smile and a shrug: "Oh, that's one of the honors of my position." In other words, there was no call for him as a boss to step down and engage in a bout with one of his men, unless actually struck first. It is amusing. and instructive too, to see how a Cornishman will handle a polyglot crowd of men whose languages he does not understand and yet be able to instruct them as to their duties. But our friend from the 'old county' has one fault, he is apt to stand in with his men, especially if they are his countrymen. A foreman who does not regard himself as identified with the interests of his employer is dear at any price, and is a sure source of eventual disorganization. It is possible for one who has men under his charge to be fair alike to them and to the owners of the mine; in fact, a foreman is really set to see that the implied contract, of honest work for reasonable pay, is carried out. Such a man can be kind without being easy, and energetic without appearing officious. It amounts to this, that the qualities that make a man capable of handling men underground are those that make a good general manager, and though the latter needs a different kind of education, the education itself is of little use unless it is allied to the comprehending insight that enables a man to direct his fellows.

By the Way.

At the recent meeting of the National Association of Manufacturers, the president, Mr. David M. Parry, said:

The industrial era has developed so rapidly, that it would have been surprising had society adjusted itself to the new conditions without friction and agitation. Only a few generations ago the employer had little capital and hired a few men, but industry brought with it its heavy capitalization and its millions of employees. While the accumulation of capital is essential to the general material welfare, yet the visual evidences of its accumulation appear to have a baneful effect on certain elements of the population, inflaming their minds with the lust for its possession and causing them to regard it as the legitimate spoils of social warfare. Those afflicted with this passion for seizing something that does not belong to them may aptly be termed industrial buccaneers.

To those who claim that it is expedient to allow the United Mine Workers of America the license to violate the law in order to prevent starvation wages I assert that the doctrine is not only that of anarchy but also that it is based on woeful ignorance of the economic law of wages. The truth is, that under free competitive conditions in the labor market, that is, under conditions where individual liberty is properly enforced, wages in all industries tend constantly to the highest possible figure, being dependent upon the productivity of the nation, and not upon the caprice or greed of employers.

As I said at the outset the industrial questions of the day are all capable of solution by the enforcement of a broadened application of the commandment "Thou shalt not steal." Industrial buccaneering cannot be permitted either by labor unions or by corporations. The members of organized labor and the corporations are entitled to their legitimate earnings and no more. When they seek either by physical force or by unfair methods to reap gains beyond those to which they are entitled under the free operation of supply and demand, when, in other words, they override the legitimate rights of the individual and the general public, they are, to put it plainly, stealing from the rest of the people. And collective theft cannot be tolerated any more than individual theft.

Corporations are needful agencies in cheapening and enlarging production, and their formation and development should be encouraged. Nevertheless, the managers of corporations must come to realize that they have no license to rob the public for the benefit of the stockholders or to rob the stockholders for the benefit of themselves. It is robbery of the public when they seek by the use of certain unfair devices to stifle competition and to charge the prices of monopoly. It is robbery of the stockholders when they use the capital of the corporation to further their own interests, an example of which was furnished us by some of those lately in charge of the great insurance companies.

The efforts of some of those in control of corporations to secure profits which neither they nor the corporations have justly earned have given rise to the demand for Government control of corporations, but such control when it means arbitrary limitation of profits legitimately earned, simply spells socialism, and as a remedy for existing evils should be execrated even more than the evils themselves. The Government has no more right to interfere with the property rights inherent in individual liberty than has a union or corporation. Its sphere of duty is that of protecting public rights, and not that of transgressing them.

It is not Government management of capital that is needed but Government prevention of industrial buccaneering of all kinds. Laws with that end in view, taken together with the growth of higher ideals of social honesty, will solve all the industrial evils now the subject of complaint. The mass of the American people are good honest citizens seeking only what they earn by their own brains and energy. The same despite all the "prejudice writing" of the day and the ranting of demagogues and socialists, can be said of the great majority of corporations. Those corporations and labor trusts, that through schemes of extortion attempt to obtain what they do not earn, are but a small part of the body politic, and they cannot be permitted either to escape punishment or to inflict socialistic oppression upon the nation. They must be made to abide by the laws and the spirit of individualistic institutions, and it is the business of the Government to accomplish this by rigid enforcement of American liberty and the rights of private ownership inseparable from that liberty. It is the business of the government to maintain and protect individualism—not to overthrow it.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

All basalts are not black, nor do all contain olivine, though some varieties carry a large amount of this mineral. Many basalts are reddish, or brown, in color. Peridotites contain abundant olivine crystals.

Novaculite is quartzite of extremely fine texture, suitable for fine whetstones. Its principal occurrence in the United States is in Kansas, though similar rock is found near Buffalo Gap, in South Dakota.

On an inclined tramway having a slope-angle of 35°, the perpendicular pressure on the rails of a ton of 2,000 lb. is 1,638.2 lb., and the stress on the rope, with a factor for friction of 2.5%, is 1,191 pounds.

Eastern investors who put their money into mining enterprises in the West without making any sort of investigation into the merits of the proposition frequently, if not usually, lose the amount of their investment.

Copper ore has been known for years to exist in slate and schist in the vicinity of Rawhide Buttes, Wyoming, north of Fort Laramie, but no production of consequence is credited to these mines. They are in the prospective stage.

Ocher found in ore deposits usually consists of silica and clay intermingled with iron oxide, and is the result of decomposition of ore, sometimes aided by attrition. Ocher is also often deposited from chalybeate springs, forming large deposits.

A sudden change in the character or richness of ore in a stamp-mill, where amalgamation is practiced, is usually promptly noticeable on the outside plates—if the millman is giving attention to his duties—and the proper remedy can be applied.

Wherever washed smooth gold is found on points, bars, and flats, high above the creek-bed of the neighboring gulches or canyons, it may be safely assumed that this gold was deposited in the bed of an ancient stream which at one time flowed at about the level where the gold is found.

The Printer Boy mine, in California gulch, at Leadville, was one of the first vein mines opened in that district. This was many years before the discovery of lead carbonate on Carbonate hill, though placer gold had been mined in California and Iowa gulches prior to the discovery of the Printer Boy, which is a gold mine, the ore occurring in gray porphyry.

Upon locating a mine in a new district, the next step of importance is the location of a water right, if any such be available. Frequently prospectors in new regions are so fully taken up with their latest discovery that they overlook the importance of water supply, which might have been secured but which is promptly appropriated by another.

Mill-launders and flumes carrying tailing should not be built on too flat a grade in cold countries or the material will freeze, causing the boxes to become clogged, the overflow resulting in loss. Flumes carrying clear water may be covered and buried in the earth, in this way preventing freezing, but a stream carrying a large amount of solid material, like mill-tailing, congeals much more easily.

Many large mining companies have found it good business to construct narrow-gauge railroads, sometimes 50 miles in length for the purpose of transporting ore and supplies between mines and reduction works, or to handle timber, fuel, fluxes, and even water. The cost of transportation on such a road depends upon its length, the grades on which the road is built, and the volume of business done over it.

In a modern sampling works all ore handling, crushing, screening and division is automatic, and the results are as accurate and reliable as human ingenuity has been able to make them. The shipper takes no greater risk than the buyer; both must depend on the work of the sampler as a basis for doing business, and the results prove that, with rare exceptions, the properly arranged sampler may be depended upon to furnish a reliable sample of any quantity of ore passed through it.

Pegmatite dikes are frequently the repositories of cassiterite, and it is not unusual to find associated with the tinstone the more rare iron ores, such as wolframite, columbite, and tantalite, besides which there are often present beryls, lepidolite, tourmalines of various colors, biotite, muscovite, albite, orthoclase, and quartz. The iron, and iron-manganese minerals may be separated from the tinstone by electro-magnetic separators, making several products of commercial value.

Rubellite is the pink variety of tourmaline, and when occurring in crystals of sufficient size, free from flaw and of good color, they are valued as gems. Tourmaline possesses a peculiar property known as pleochroism—that of appearing to be of different colors by transmitted light, when viewed in the direction of the different axes of the crystal. This property is sometimes taken advantage of in the optical examination of thin sections of minerals under the microscope.

There are four zones to be recognized in sulphide-bearing veins. A zone of complete oxidation; one of oxidation with secondary enrichment; one of secondary sulphides; one of primary sulphides. The first may owe its precious-metal contents to mecnanical concentration from eroded parts of the vein as well as to residual values, and is not a safe index to deeper parts of the vein. The second may owe its precious-metal contents to chemical concentration as well as to residual values. The third is likely to be abnormally high in base-metal contents as well.

It has been decided by the Supreme Court that where the extra-lateral rights of two mines conflict underground, by reason of converging direction of end-lines, the senior locator shall be entitled to the uninterrupted extension of his vein, on its downward course between the vertical planes determined by the end-lines of his location, extended in the direction of the dip of the vein, and that the junior locator may take a similar right down to the zone covered by the rights of the senior locator, through which he is entitled to a right of way. He may then take his extra-lateral right on the further side of that of the senior locator.

It is supposed that the deposits of calcium borate (colemanite), and other borax minerals occurring in California, were derived from hot springs, the water of which contained boric acid, but which springs are now extinct. Springs of this character are only known to occur in volcanic regions and the only known borax mineral deposits in California are found where volcanic rocks abound. In Lake county, California, some years ago a valuable deposit of borax was discovered occurring as an efflorescence on the surface of a dry lake. A large amount of the mineral was collected and sold at good profit, but the cupidity and ignorance of the owners proved their undoing. They sank an artesian well in the lake bed expecting to strike a body of water saturated with borax, instead of which they encountered a strong flow of fresh water, which covered the floor of the lake, dissolved the borax, and brought their previously profitable business venture to an abrupt end.

The most noted placer mining districts of Honduras are in the department of Olancho, of which Juticalpa is the principal town. The most important gold-bearing streams are the Guayape, Parnel and Jutiape. Along the banks of these streams, which rise in the Guaymaca mountains, after they flow out upon the valley, are extensive deposits of gold-bearing gravel. In the vicinity of the village of Concordia also are large banks of auriferous gravel. Within two or three miles of the latter place, at Llano Viejo, an old mining town now in ruins, are several quartz mines, which evidently were worked many years ago. There are numerous old arastra beds along the neighboring stream, showing that at one period an extensive industry flourished there. The rocks of the vicinity are limestone, mica schist and intrusive dike rocks, particularly diorite. These districts are from 55 to 65 miles westerly from the town of Juticalpa, and nearly 80 miles easterly from Tegucigalpa, the capital of the Republic.

The age of the mineral-bearing rocks in Yavapai county, Arizona, is, for the most part, uncertain further than that they are mostly known to be pre-Cambrian. The sedimentary beds of the Grand Canyon region, which extend from Cambrian to Permian, overlie crystalline schists, and this area of schists, granites, etc., extends for many miles to the southward from the Grand canyon. It is improbable that these schists contain mineral veins carrying gold, silver, copper and other ore, but in the Grand canyon these are rendered almost valueless by reason of the extremely rugged topography of the country. In some portions of the canyon the overlying Cambrian rocks also contain ores—chiefly those of lead and silver, particularly in Cataract canyon. Some development has been done on these deposits, but like the veins in the schists, they can only become commercially valuable when a cheap means of transportation, from the depths of the canyon to the plateau at the top, has been provided.

Sinking vertically through sedimentary rocks which lie nearly flat, and which show many alternations in the character of the beds composing the strata—one stratum being hard, and the next soft—will often occasion much difficulty in blasting, particularly when the several strata are only a few feet or a few inches in thickness, as is often the case in unmetamorphosed sediments. When drilling through a hard layer, upon the drill-bit reaching the bottom of the stratum, a blow from the hammer drives it suddenly and unexpectedly downward, perhaps several inches, into the underlying soft stratum. To fill and tamp the hole in the soft material, effectively, so that the powder will blast out the hard overlying rock is a difficult matter. It is usually the better plan to abandon the hole and drill another near it which will be deep enough to blast out the hard layer, when the soft bed beneath may be picked out. Occasionally the bottom of the hole, which has entered the soft ground, may be chambered with a half-stick of dynamite, and the chamber filled with black powder. It is then an experiment whether the black powder will enlarge the chamber previously made, or break the hard layer above it. The situation is one requiring experience and good judgment on the part of the miner.

Sedimentary rocks are those formed of the material derived from the disintegration of other older rocks. This material forms conglomerates, sandstones, or shales, depending upon the character of the rock supplying the detritus, and also to some extent, upon the distance it has been moved, the carrier being most commonly water. The coarser materials are first deposited, such as the silt, sand, pebbles and cobbles forming conglomerates on a sea or lake shore. Sediments carried in suspension by rivers settle to the bottom when the current becomes sluggish, on entering the deeper water, the coarser sands being deposited first while the finer silt is carried many miles further. The sorting action of the water is perfect, and the only difference observable in sedimentary deposits thus formed is in the stratification produced by the varying volume and character of the materials brought down by the stream at the several seasons of the year. Thus, in stages of high water the stream will discharge a much larger amount of sediment, which will average coarser than that carried down during low water. Volcanic ejecta—rocks, sand, ashes, and mud, may also be carried by streams into deep water forming sedimentary rocks upon consolidation.

Concerning the location and recording of mining claims, the United States law says: "The miners of each district may make regulations not in conflict with the laws of the United States, or with the laws of the State or Territory in which the district is situated, governing the location, manner of recording, amount of work necessary to hold possession of a mining claim, subject to the following requirements: The location must be distinctly marked on the ground, so that its boundaries can be readily traced. All records of mining claims hereafter made (May 10, '72) shall contain the name or names of the locators, the date of location, and such a description of the claim or claims located by reference to some natural object or permanent monument as will identify the claim, etc." It will be noticed by the foregoing that miners may organize districts and may also determine the manner of recording. This, without doubt, contemplates the election of a local district recorder, and any record of location properly made with him in accordance with the United States statutes would be perfectly legal. The language of the Civil Code of California, Section 1159—"notice of location may be made with the county recorder," etc., does not make it compulsory. A safe plan would be to record a location with both the district recorder and the county recorder. The county records are usually kept in a safe place where they are not likely to be destroyed by fire or otherwise, while in many cases those of the district are exposed to danger of destruction. If a mining claim is worth anything it is worth recording in such a manner as to insure the validity of title.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

THE TREATMENT OF DESERT ORES.

The Editor:

Sir—One of the first requisites of good criticism is that the critic shall at least give his victim a fair hearing. I refer to certain strictures, in your issue of April 28, on a brief article of mine touching upon ore treatment in the Tonopah-Goldfield district. If unwittingly I have trodden rough-shod on any of Mr. Bertram Hunt's metallurgical hobbies, I am sorry; but before proffering a formal apology I must ask him to do me the justice to re-read my article, which he so bluntly dismisses and so obviously misunderstands.

In reference to the necessity of amalgamation at the Combination mill at Goldfield, I was not undertaking, as Mr. Hunt infers, a general discussion of the treatment "of oxidized ores of the desert regions of Nevada and California." The classification of 'desert ores' is Mr. Hunt's own. It seems to me a poor one, because all sorts of ores are found in the desert, requiring various modes of treatment; and variations quite as pronounced are found in mountainous regions and high altitudes. Hard ores are found in the desert, as well as soft ores; oxidized as well as sulphide; and any technical man familiar with desert conditions, especially those observable at Tonopah, Goldfield and Bullfrog, would hardly fall into the blunder of making so meaningless a classification.

I was not generalizing when speaking of ore treatment at the Combination mine. I was plainly referring to a specific case of an unusual type of oxidized ore, peculiar to a limited district. Mr. Hunt advocates dry crushing as applied to the soft, oxidized porous ores of the desert, under the impression, evidently, that this is the sort of ore found at Goldfield, and that it is characteristic of the deserts of Nevada and California. This is an error into which others have fallen who are not acquainted with the southern Nevada fields. The oxidized ores of Goldfield are not porous, and they are not soft; in fact they are extremely hard. The ore of the Combination mine has been described as a silicified andesite. It is so hard and tough and fine-grained that selected pieces of it have been considered suitable for replacing the flint pebbles in the tube-mill used for re-grinding the softer sulphide ore. Some idea of its hardness may be gathered from the fact that 1,300-lb. stamps, with 6-in. drop, falling 100 times per min. will, under the best conditions, put only 3 to 3½ tons per stamp per day through a 12-mesh wire screen.

Mr. Hunt bewails "the present fashion of putting in stamp-mills and amalgamating arrangements followed by a cyanide annex, as due solely to the compelling power of custom." If such is the prevailing practice, it is much to be deplored; and I regret it no less than he. But the allusion so palpably insinuates that I have offended in the case of the Combination mill that I hasten to relieve Mr. Hunt's anxiety on this score by offering a few facts.

The Combination mill at Goldfield was not installed until the treatment of the ore had been thoroughly investigated. This required about six months. Laboratory tests were confirmed by milling tests. Dry crushing was given a fair trial, but the extraction in each instance was poor; and after fifteen days' leaching with the ordinary strength of solution used on gold ores, it was still found possible to pan from the tailing considerable quantities of gold undissolved by cyanide. Several strengths of solution were tried; the ore was reduced to various degrees of fineness; and still dry crushing was not applicable. Finally wet crushing under stamps, followed by amalgamation, concentration and cyaniding, was found to be the proper treatment, and was adopted. I do not propose to enter here into the details of treatment, as I am reserving this for a special article. But suffice it to say that contrary to Mr. Hunt's belief, the matter of ore treatment was given a thorough study; and we were not, at least in this instance, the slaves of custom.

In regard to the recovery of gold on plates; I would certainly advocate the use of amalgamation where as much as 50% of the gold can be so recovered. Mr. Hunt is possibly not familiar with the character of the gold found in the Goldfield district. It is fine, to be sure, as distinguished from the coarse gold of the California Mother Lode, which yields such high results to amalgamation; but it is not by any means invisible, and most of it can be 'panned out' in an ordinary miner's pan. In other words, it is too coarse for direct cyaniding and too fine for the best results by amalgamation. Moreover, Mr. Hunt has evidently not considered the great advantage of being able to secure daily from plates 50% of the extraction obtained from $50 ore, as compared with waiting for the tedious monthly or bi-monthly clean-up in a cyanide plant and his suggestion that amalgamation be tried after cyanide treatment by passing the tailing "over some amalgamating device," while no doubt ingenious, will hardly appeal seriously to practical mill-men. And what, let me ask, does Mr. Hunt propose to do with the very high-grade concentrate obtained from this ore, which it pays so well to extract and ship? Must this also be removed after cyanide treatment?

My critic's views on this whole subject are summed up in his query, "As the majority of these oxidized ores give a practically complete extraction by direct cyanide treatment, what is the advantage of using both amalgamation and cyanide to recover the same value?"

My answer is that I do not admit the correctness of Mr. Hunt's premises. He is evidently an ardent advocate of dry crushing; and while I did not intend to prolong this discussion into a consideration of the respective merits of the two processes, I cannot refrain from mentioning some of the more serious limitations of dry-crushing. A few years ago I was happily instrumental in converting one of the largest dry-crushing plants in the West (that of the Gold Road mine in Arizona) into a wet-crushing mill. It was an expensive and well-equipped plant and had been in operation several years; and so far as I could see, it had been worked to its highest efficiency. The extraction obtained was about 80%. The change to wet-crushing, using Huntington mills in conjunction with the coarse rolls already installed, and Dehne filter-presses to handle the slime, raised the extraction 10%, and considerably decreased the cost of treatment. Amalgamation, in this case, was dispensed with altogether, as only about 15% of the value could be so recovered. Two other representative dry-crushing mills, one in Utah and the other in southern California, are now considering the remodeling of their plants for dry-crushing, after obtaining promising experimental results.

These projects and changes are all based upon the following facts, which I believe will sooner or later reduce the applicability of dry crushing to a few rare and isolated cases: (1) The impossibility (from an economic standpoint) of reducing ore to a sufficient fineness to ensure the best recovery, without making percolation prohibitively slow. (2) The now generally accepted view that the product of any ore-crushing mill must be handled either as a slime, or as classified sand and slime. The slime requires short treatment with weak solutions; the sand, long contact with stronger solutions. Every modern mill, operating on a logical basis, must handle its final cyaniding material as two separate products.

Aside from the great discomfort to workmen in a dry-crushing mill, and the resulting well-grounded prejudice which they have against these mills, the great fundamental objection to this type is that it is not adapted to the requirements of the latest and best practice in cyaniding. An exception to this would be in the treatment of a porous ore containing little or no amalgamable gold, and requiring hardly more than breaking, like the ore formerly treated in the old Mercur plant, or an ore which requires roasting before cyaniding. Conditions so ideal for dry crushing are rare; at least they are not common enough to affect the general rule prescribed above.

Mr. Hunt mentions, among the objections to wet-crushing, that the moisture in the ore must be displaced, entailing a loss of cyanide. This would be a very serious matter indeed if there were no conceivable objections to dry crushing. Each method, of course, has its objectionable features. The discussion of so important a subject should be undertaken in a fair and liberal spirit; the merits and demerits of each process carefully weighed; and obviously the final choice accorded to the method which has the preponderance of commercial advantages as applied to a particular ore. After a careful study of the two methods, and some experience in both, I, for one, am persuaded that the present recognized need of fine grinding in cyanide work, and the treatment of slime as a separate product, will ultimately reduce the field of dry-crushing to a very limited scope.

FRANCIS L. BOSQUI.

San Francisco, May 10, 1906.

BLAST FURNACE VS. REVERBERATORY.

The Editor:

Sir—I feel that Mr. Mathewson's article in your issue of March 24 would do us lots of good if we could manage to figure out his diagram there given. In the diagram, where is the line of no values and in which direction do they increase? If a two per cent copper ore carrying 30% silica fetches the amount shown next to 30 on the bottom line of the diagram, will the next value of a two per cent ore of 70% silica be shown next to 70 on the same horizontal line? Will the value of a seven per cent copper ore with 30% silica be shown on the horizontal line 7 and the inclined line 30, and will a 7% ore containing 7% silica be found on the same horizontal line? Also where shall we find the net value when treating the latter in a reverberatory?

It would be interesting to know what it costs to treat a ton of materials at the blast-furnace, that is the ore and flux, excluding the weight of the coke and the cost of the flux.

AN OLD SUBSCRIBER.

Chicago, May 12, 1906.

INFORMATION WANTED.

The Editor:

Sir—The Laurentian mine, near Dinorwic, in Ontario, Canada, on the Canadian Pacific Railroad, about 200 miles west of Port Arthur, is pumping water from a lake to its 20-stamp mill, a distance of 3,000 ft. against a head of 120 ft., through a 5-in. standard black-iron pipe. The line is entirely above ground, supported by wooden trestles of varying heights up to 26 ft., giving a uniform grade so that the pipe may be drained when not pumping. During the winter the temperature is often 45° below zero, thus requiring a covering for the pipes to keep the water from freezing.

Should any of your readers have had any experience in protecting water-pipes from freezing under similar conditions I would be pleased to have them advise us in your columns. ANTHONY BLUM.

Gold Rock, Ontario, May 8, 1906.

Lead Pencils are not made of lead, as some suppose. They are made of graphite and clay. Graphite is mined in much the same way as coal. The greater part of the graphite comes from Bavaria. After being mined, it is sent to the pencil factories, where it is ground to powder and mixed with finely pulverized clay. On the amount of clay depends the degree of hardness or softness of the pencil. The greater the portion of clay, the harder the pencil, and vice versa. This mixture is thinned with water and repeatedly ground until it is perfectly smooth and free from grit, after which it is placed into canvas bags and squeezed until sufficient water has been removed to make it of the proper consistency. It is then placed into a strong cylinder with holes at one end of the same size as the leads which it is desired to make. A descending piston forces this mass through the holes in long strings, which, after being thoroughly dried, are subjected to intense heat, after which they are ready for their wooden cases. The wood part of the pencil is usually made of red cedar. This is sawed into small strips, grooved, lead inserted and the strips glued together, after which they are rounded, polished, cut into the proper lengths, etc.

Oil in Illinois.—The oil fields recently found in eastern Illinois continue to develop and have now reached a production of over 60,000 barrels per month. The oil is of good grade, yielding about the same percentages of the lighter distillates as the Indiana oil. The wells produce from 5 to 25 barrels a day, and while there are no gushers known, they have not yet been exhausted, although some have been pumped since last June. The proved territory extends from Westfield, in Clark county, to Robinson, in Crawford county, and is perhaps connected with the Mermon, Indiana, field. The oil is found in the coal measures at depths of from 300 to 900 feet.

Cement in 1905.—A preliminary statement on the production of hydraulic cement in the United States during the calendar year 1905 has been issued by the United States Geological Survey. It shows that the total production of all kinds of hydraulic cement in 1905 including portland, natural rock, and slag or puzzolan cements, was 40,894,308 bbl., valued at $36,012,189. This was an increase of 9,219,051 bbl., valued at $9,980,269, over the production of the previous year. Of the total amount of cement manufactured in the United States in 1905, 36,038,812 bbl. were portland cement with a value of $33,326,523; 4,473,049 bbl. were natural rock cement valued at $2,413,052; and 382,447 bbl. were slag or puzzolan cement, valued at $272,614.

Joplin Re-visited.

Written for the Mining and Scientific Press by
F. Lynwood Garrison.

After an absence of over six years it is interesting, and perhaps instructive, to note a few of the changes which have taken place during that period in this remarkable mining region. The most striking characteristic of what is known as the Joplin district, is the enormous area it covers. The numerous small mining towns and camps comprising it are scattered over a large section of southwest Missouri and a few miles across the border into Kansas and Indian Territory. This condition is due to the fact that wherever lead and zinc ores were discovered in any quantity, camps and small towns sprang into existence. These places are often many miles apart, but they are all evidently in one and the same mineral area and horizon. Gradually the intervals or gaps between these towns are being prospected, and I venture to say in most cases where this work has been carefully and intelligently done, ore has been found. Deeper drilling and closer prospecting will certainly tend to uncover orebodies in ground previously supposed to be barren, and, with a better understanding of the structure and nature of these deposits, it is to be expected that this development will continue.

As a result of such development, this entire territory is likely to be sprinkled with a multitude of new producing camps, a few of which may prove to be as rich and as extensive as any yet found. Some of the older mines, notably those close to the settlements of Joplin and Webb City, have probably been pretty well exhausted; but I make this statement hesitatingly in view of the repeated instances of old workings, given up as thoroughly depleted, becoming once again producers. The supposition that the ore reserves of the district are becoming exhausted is certainly not justified. My own opinion is that their extent is but just beginning to

BOILER FIRED WITH OIL.

be realized. Whether the new finds will continue to be as rich I doubt, for the tendency seems to be to discover larger bodies at greater depth, but of much leaner character. These deeper lodes are probably the primary aggregations not enriched by secondary concentration, as in the case of the shallow deposits.

That there is likely soon to be an over-production of zinc ore, I do not believe; at the best the orebodies are relatively small and scattered, hence it is extremely improbable that the cost of production can be materially reduced notwithstanding the economic advantages possessed by the district as a whole such as natural gas, cheap electric power, etc.

The subject of labor is becoming a rather serious one in the Joplin region. The scale of wages eight or ten years ago ranged from $1.25 to $2 per day. Now, for the same work, they average from $2 to $2.75, and in some cases, I understand, even more. This increase was, of course, justified by the greatly enhanced price of zinc ore, but it is doubtful whether the very high rates for ore that have prevailed for the past year can be maintained in the near future. It is probable that the average operator in this district is usually working on a small margin of profit between the cost of his ore and its market value. In view of this condition and the fact that the cost of food is nowhere lower in the United States than in and about the Joplin district, such a great increase in wages is apparently unjustifiable. Whenever a great drop comes in the price of zinc ore, as it will inevitably, it surely will be difficult to reduce wages proportionately, and the operator will then have to suspend, pending better prices for his product.

On the whole the personnel of the labor here is good, pure American stock. The miners are recruited mostly from the farms of southern Missouri and eastern Kansas; there are but few foreigners among them, and the miners are, as a rule, as good a lot of boys as could

YELLOW DOG MILL.

be desired. Labor unions have never been successful in organizing in this region, chiefly for the reason that conditions here are peculiar in that a miner who is working for wages today, may tomorrow become an operator. Many, if not most, of the operators have begun as miners; hence the relations between operator and miner have naturally been sympathetic, and this should make possible an amicable adjustment of the cost of labor to the price of ore.

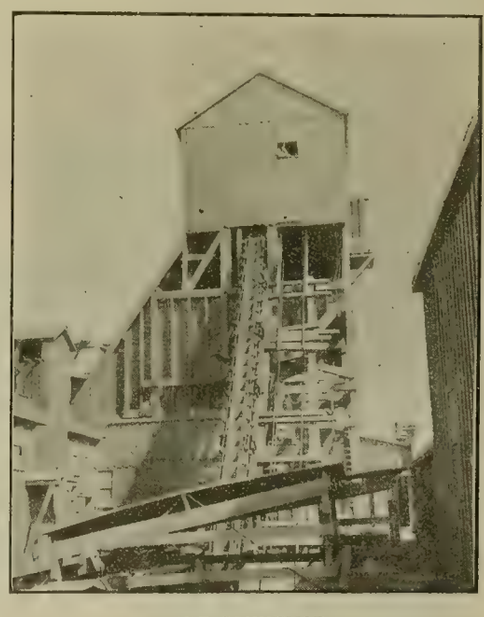
The introduction, within the past six months, of natural gas from the fields of eastern Kansas, has placed Joplin in an enviable position as regards fuel. This gas is sold to the operators at 10c. per 1000 ft. when used under boilers to generate steam, and 25c. per 1000 ft. when consumed in gas-engines. The method of applying it to a boiler previously using coal, is very simple, as is well shown in the accompanying photograph. A few feet back from the nozzles, a checker-work of firebrick is built upon the hearth which acts as a baffle-plate or wall upon which the ignited gas impinges, thus spreading the flame and preventing a too rapid escape of heat up the chimney. The pressure is regulated and the gas measured by suitable apparatus placed a few feet outside the boiler-house.

In addition to this cheap form of fuel, the operator has the option of taking electric power from the new central station of the Spring River Power Company situated on Spring river at Lowell, Kansas, a short distance across the border from Joplin. Here a substantial and excellent plant has been established with eight turbines, four connected to each of two 2000 h. p. dynamos. As the water flow at times is apt to be rather irregular a supplementary steam-plant is being installed by this company that will give the requisite power should the water fail temporarily. The electric service sold by this company to consumers costs from one to four cents per h. p. h., depending upon the amount used. Certain discounts reduce this cost somewhat when large quantities are used.

I have been unable to find much improvement in the general milling practice of the district as a whole. Some mills grind a little finer and use tables, but the waste in the average mill is still great. While from an academic standpoint such extravagance appears inexcusable, I believe, from the practical result, that the Joplin mill justifies its continued existence. It is crude, but cheap, and can be moved easily in this flat country from place to place; in fact, it may almost be considered itinerant. The pockety nature and irregularity of the orebodies rarely justifies a large and complete plant; moreover, for the same reason large custom mills are not favorably regarded. The chief objection to the small individual mill is the relatively enormous expense of power generation, and the impossibility of such plants affording first class superintendence. The first difficulty is, as we have observed, being overcome by the use of gas and electric power; while the second may be, and perhaps is being, met by the consolidation of a number of small properties under one management. Certainly, more low-grade ore is now being treated than ever before. By 'low-grade', I mean a raw ore that contains about three per cent of zinc-blende or 'jack' per ton. A more general use of electro-static separators will also tend to greater economy, especially when used with concentrating tables. Although there is much room in this district for improvement in both mining and milling practice, the engineer who visits the place for the first time should not jump to conclusions regarding the crudities he witnesses. The operator here is a very practical person, he seldom has the means or the desire to secure highly skilled engineering advice. No doubt he would save money thereby in the long run, but he usually knows his business and often makes a success, where perhaps a more highly trained technical man might fail. Certainly college-trained mining men are conspicuous by their absence in this region, though, of course, there are some successful exceptions.

One of the novelties I observe here is the mill near Webb City, shown in the accompanying photograph, and known by the classic name of Yellow Dog. Its chief peculiarity is that the ore is raised from the mine by a bucket-conveyor arranged upon a kind of link-belt affair; the construction is simple as will be seen from the photograph. Such an apparatus is possibly effective, but I have some doubts as to its economy. It is true the lift is not great and the weights are relatively small. This mill is also exceptional in being completely equipped with electric power from the central station at Lowell.

The prosperity of Joplin is well indicated by its busy business streets and the substantial and expensive character of its new private residences. It also boasts of a really handsome post-office building, a Carnegie library, Elks Club, and several handsome new churches. With such remarkably cheap fuel, excellent railroad facilities, cheap land and good water, Joplin should become a manufacturing center. The district is so favored by nature that my modest account of its advantages may appear like an exaggeration and give this article an aspect of what I believe newspaper folk call a "write-up." Certainly nothing of this kind is intended. To show my sincerity in this respect, I should perhaps



ORE CONVEYOR.

end up by saying something nasty about Joplin. Well, I must think! Its dames are fair and its men are brave, but it is awfully hot and disagreeable during fly-time in summer and it has more saloons to the inhabitant than any other town in Missouri.

The advance statements of the Canadian Geologists are included in the summary reports of the Geological Survey of Canada. The volume for 1904 of this series has recently appeared, but some of the separate articles were printed many months ago. A praiseworthy feature of this publication is the illustration by maps reproduced in colors. It appears that the Canadians have found means of producing illustrations in color expeditiously and in this respect are ahead of the survey in our own country. The value of this series would be much enhanced by the inclusion of an index to each volume. While most of the reports are concise statements, some could be condensed without losing anything essential. The publication would gain both in clearness and attractiveness if a more logical and less monotonous form of paragraphing were adopted.—A. H. Brooks in Economic Geology.

Notes on Tube-Mills at El Oro, Mexico.

Written for the MINING AND SCIENTIFIC PRESS by CHARLES BUTTERS.

Foundations.—The management of El Oro Mining & Railway Co. had a good deal of trouble with the foundation of one tube-mill, due to improper setting of the cement. There is a terrible vibration when the mill is running. It would be best to make the foundations ten per cent heavier than the plans usually called for, using the very best cement, and allowing sufficient time to set clear through before the tube starts. Underneath there should be a good cement floor sloping to a gutter leading to the cone, spitzkasten, pump, or wheel, constituting the return circuit, so that the floor can be washed with a hose, the washing being returned with all leakage of mills for re-grinding.

Rotation.—It is important that the tubes rotate in a direction such as to cause the thrust of the driving pinion to be downward into the pillow-block, and not up against the cap; the rotation should be effected by an open belt, if possible. If in accomplishing this the mill runs backward, it is best to reverse the spiral in the feed-throat, as the spiral is the only thing that makes any difference to the direction of rotation. The spiral at the discharge end can be removed altogether, as it seems to be of no practical value, mills working just as well without it, as others with it on the same work.

Leaks.—A leak will often start around a bolt when it is impracticable to shut the mill down. If there is a cement floor, it will make no difference, or a bolt may cut out entirely. In this case, feel in the hole with the finger and if the liner is good, put a wooden plug in the hole until such time as is necessary to shut down for more extensive repairs. If the leak occurs at the head of the mill, the sand will get into gears and cut them badly. This can be obviated by putting a shield on the gear-wheel rim, to cover outside ends of teeth, by fastening (with cap-screws) a ring cut from sheet-iron No. 14 or 16 gauge. This should, by all means, be done before the mill is set up.

Feed.—In case the feed-hopper and the pipe that enters the mill come in one piece (as they did at El Oro, cut the pipe off as close to the hopper as possible, and put in a flange or sleeve, threaded in direction, so that the rotation of the mill will not screw it off. The pipe will have to be made a little longer than the piece cut off, as the connection will necessitate setting the hopper further back, in order to get at the packing gland. There is a great deal of wear on the pipe. By this means it can be quickly and easily replaced. The best packing to use is ⅜-in. common hose cut in individual rings. There should be a de-watering cone, or pulp-thickener, directly over the feed-hopper, to get the pulp as thick as possible for the mill—1 to 1, or less. The overflow from this can be carried over the mill into the discharge-box to dilute the pulp again so as to make it flow through launders.

Platform.—There should be a platform over each mill, with a hopper over each man-hole for putting in pebbles, and the pebbles should be brought in at this level if possible, to avoid elevating them. The lifting of pebbles into the side of the mill is a slow and laborious job. This platform would give access to the pulp-thickening cone also. With everything arranged in the most convenient manner, the mills should run a maximum of 29½ days per month. If there are only a few pebbles to put in, two or three men will distribute them easily, but if there is a great quantity to add it is quicker to fill the mill full up to man-hole, put on the door temporarily, and give the mill a few turns to distribute them, repeating the operation until sufficient pebbles have been introduced. At El Oro they keep the mills one to three inches more than half-full, by measurement from top tube to pebbles. When the mill is opened for repairs the foreman measures the pebbles and can tell the workmen just how many sacks to add. They never allow them to wear down more than four inches before refilling.

Liners.—The Krupp liners at El Oro are 1½ in. thick, of chilled cast iron; the chill is only about ¼ in. deep, and when it wears off, the balance of the plate wears much faster. The wear on the plates is chiefly at the head of the tube, and diminishes with each row of plates toward the tail. The average life of Krupp plates being 40 days, with mill No. 3, running 32 rev. per min., containing 7½ tons of pebbles and grinding 125 tons of sand per day, of a very hard quartz, producing about 50% of material that will pass 200-mesh, 40% of the remainder being between 100 and 150-mesh. They are now making their own plates, 1⅛ in. thick, of white cast iron, not chilled, but it is run in very thin sand molds. The founder has a formula for this casting, which produces a very hard metal clear through, and wears evenly and equally down to a quarter inch or less. It was not possible to get the exact composition of the iron, but any intelligent foundry-foreman could soon test it out, as a hard, white casting is made by using re-melted iron until it is very low in silicon, and adding a little sulphur. No. 3 mill has four rows of plates, with three holes each. The length is to be changed, making three plates with two holes each to take the place of two plates, and make them 1½ in. thick. At El Oro they never empty the mill to re-line it, but put in one or more plates at a time as needed, with the pebbles all in. Thus the 1½-in. short plate will be lighter to handle than the 1⅛-in. long plate, it will last longer, and if one breaks before it is worn out (as they sometimes do), there will be less iron to throw away. These plates wear much longer than Krupp plates, and cost just half as much. The plates must be cast true to curve, the holes very carefully cored, and the bolts forged from common iron to exact taper of hole. When the plates are put in, see that the core sand is thoroughly cleaned out of hole; place two men inside and two outside of mill; take two rods 2 ft 6 in. long to pass through the holes, so that the men outside can help to lift the plate, the rods guiding it to exact position. The men inside can easily hold it in place, while the rods are removed, one at a time, and the bolts put in. Drive the bolts to a firm and close seat, with a sledge, while the nut is being tightened with a 2-ft. wrench, using a washer and gasket of ⅛-in. sheet-packing under the nut. If the plates are well put in so there is no spring and the bolts fit perfectly, they will wear evenly down to ¼ in., without breaking or causing any trouble. Four men, after they become familiar with the work, will take out old plates and put in new at the rate of about three per hour.

At El Oro they have found that the end-discharge plate or grating discharged pebbles too large, causing undue waste, and have thus replaced these with others containing oblong holes ⅝ in. by 1½ in., there being 48 holes in each half plate. An experimental run has been made with mills in series, that is, running all the coarse sand into one mill, and the fine return sand into a second mill. The consensus of opinion is that this is the best and most economical method and they are installing two new mills, to be put in series with the old ones. The pebbles discharging from the first mill are put into the second, where a fine discharge grate is used, the pebbles finally issuing being not more than ⅜ to ½ in. The discharge must be into an open box containing a screen with about ¼-in. holes to catch the pebbles. They have in use a No. 5 mill, 5 ft. diam., 27 ft. long, inside measure, running 28 rev. per min., containing 16 to 17 tons pebbles and 8,640 kilo. liners, requiring 107 h. p.; a No. 4 mill 5 ft. by 24 ft., 28 rev. per min., containing 11 to 12 tons pebbles, 7,520 kilo. liners, and requiring 85 h. p.; and a No. 3 mill, 4 ft. 1 in. by 19 ft. 9 in. running at 32 rev. per min., containing 7½ tons pebbles, 4,520 kilo. liners, requiring 60 h. p. They have determined, after several months' careful observation, that the No. 3 mill is the most economical and efficient to use, and, in future, they will install no other size.

The consumption of pebbles and liners for the months of October and November, 1905 (mills running 95% of the time), was:

	October.		November.	
Mill No.	Pebbles	Liners	Pebbles	Liners
	Kilo.	Kilo.	Kilo.	Kilo.
3	5,165	1,365	5,370	1,360
4	8,625	729	10,625	2,589
5	7,987	1,345	16,310	2,589
Total,	21,777	3,439	32,305	6,538

The mills were grinding about 8,700 tons per month of battery sand, besides the return sand.

In my opinion it would be a great advantage to have the liner-plates short, as mentioned above, for there is little room in a No. 3 mill; no more than two men can work to advantage, and the plates should be light enough, so they can be handled quickly and easily. But it would be a great mistake to make them with only two holes, because if a bolt cut out, the leverage of the plate on the other bolt will soon break it, causing an endless amount of trouble, necessitating a shut-down to replace a bolt at once. With three bolts in a plate, if one comes out, the other two will hold the plate firmly in position until such time as is necessary to shut down for more extensive repairs.

San Francisco, Dauntless.

The California Promotion Committee issues the following truthful and interesting statement:

On April 18, 1906, San Francisco experienced an earthquake followed by a disastrous fire of four days' duration which swept over four square miles of densely populated area.

The earthquake did some damage to poorly constructed buildings, but it was demonstrated beyond a doubt that the modern building of the higher type is not affected by seismic disturbance.

The disastrous effects of the fire were appalling, the loss running into the hundreds of millions of dollars with insurance of possibly two hundred millions. All of these millions and more will seek reinvestment.

Fortunately the water front was not seriously damaged and the vast shipping through the finest harbor in the world was but little disturbed. Many manufacturing plants and a large section of the residence district of the city remained intact.

Within a few days after the catastrophe street cars were running on several streets and on Market Street as far as the Ferry. This traffic was extended day by day until now it is fast approaching normal conditions.

At three o'clock on the afternoon of April 18 a Citizens' Committee was organized for relief and for the regular business of the city. This provisional government by committees worked in admirable harmony with the mayor and Federal authorities and at once developed an orderly and wonderfully efficient plan of operation.

The health conditions remained wonderfully good. At no time was an epidemic threatened. The loss of life was comparatively small, many a minor catastrophe in recent history having resulted much more disastrously in this respect.

Business confidence remained unshaken after the disaster and the banks all demonstrated their solidity. At no time was a panic threatened. Before the ashes cooled wholesale and retail trade was resumed in original places where the buildings remained and in temporary structures in cases where the buildings had been burned.

The people of San Francisco, millionaires and wage-earners, refugees and householders, showed a spirit of fortitude and optimism probably unequalled in the history of the world.

San Francisco is now in course of reconstruction; the debris is rapidly being removed and the hum of industry has supplanted the roar of the flames. The abiding results of the fire will be wider streets, more imposing edifices, larger parks, and a complete fire-fighting system which will utilize the waters of the ocean. The real estate market weathered the storm and shows great activity.

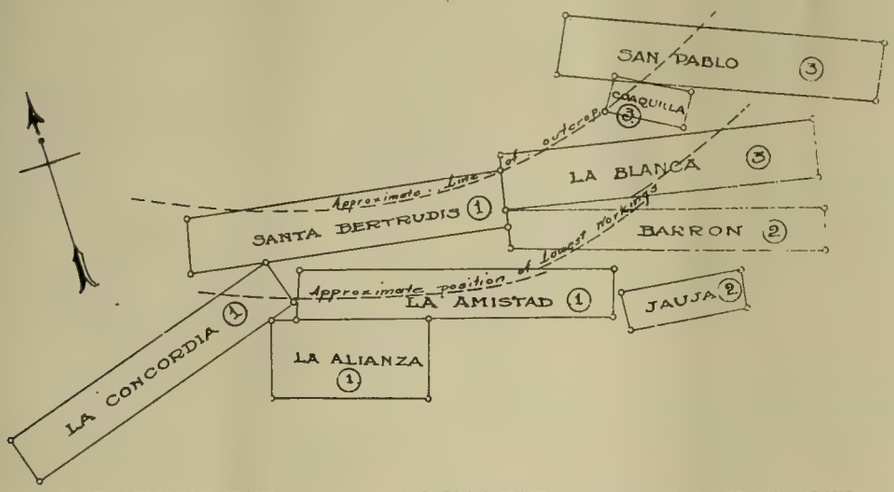
San Francisco is the city of opportunity. The vast fertile country back of it promises the yield of an exceptionally good year's crop. The chance for business investment is magnificent; Eastern and local money will be poured in freely while the rebuilding progresses. The history of all such events as that which has just transpired proves that the ultimate result is a general improvement in conditions and a vast increase in community wealth.

Quartz Glass.—Pure quartz melted down to glass has numerous valuable properties not possessed by any other kind of glass. It expands less than one-tenth as much as common glass upon heating; it can be heated to 1000° C. without becoming soft, and it has been found to transmit ultra-violet rays with freedom. These properties make quartz glass an article of great value in the laboratory. Numerous experiments have been tried in an endeavor to produce quartz glass in amounts which would make it of practical utility. After many trials and failures it was found that a mass of pure quartz, either transparent or milky, could be readily melted, and be freed from damaging air vesicles, by placing in an electric furnace of such construction as would permit subjecting the charge to compression of air. The quartz was rapidly heated to above 2,000° C. before the air pressure was applied, after which the temperature was lowered to the proper point. The result by this method was the repeated production of sheets of quartz glass 3 by 5 by ½ in., almost entirely free from objectionable air bubbles, those present being small and not numerous. The presence of metallic oxides of any kind, even in very small amount, renders the glass unfit for use, making it almost black and opaque. The quartz must be free from impurities of every kind, or the glass produced is opaque.

Pachuca.

Written for the MINING AND SCIENTIFIC PRESS by
H. E. WEST.

Pachuca, in the State of Hidalgo, is 62 miles northeast of Mexico City. The town is situated at the foot of a range of barren hills, of extrusive origin, built up mainly of andesite. The altitude is about 8,000 feet above sea-level. The topography is mountainous and broken. The immediate vicinity is unattractive, except in the neighborhood of Real del Monte, where there are beautiful 'bosques' or woods, principally of oak. The climate is not equal to other portions of the southern tableland. The winds are most disagreeable, and in winter decidedly chilly. During the past winter there was twelve inches of snow on the hills around Real del Monte; this, however, is exceptional.



1. SANTA GERTRUDIS GROUP. 2. BARRON GROUP. 3. LA BLANCA GROUP.

A NOTABLE SERIES OF MINING PROPERTIES.

The district, as a producer of precious metals, is a very old one, and was one of the first worked by the Spaniards, three centuries or more ago. As is well known, it was here that Bartolome de Medina discovered the principle of amalgamation in the early sixteenth century, and developed the famous 'patio' process, through which, until recent years, all the enormous silver production of Mexico was extracted.

The Real del Monte and the Santa Gertrudis mines are the oldest in the neighborhood. The latter has paid the present company—not the only one to own and work this rich piece of ground—403 dividends, and today pays regularly a monthly dividend of one peso*, or about 17% on the present market value. The Amistad and Concordia are the 'deep-levels' of the Santa Gertrudis, and all ore now comes from these properties, the outcrop mine having been worked out many years ago.

Looking at the Pachuca of today there appear to be three centers of activity: The Real del Monte district, five miles northeast of Pachuca; the Santa Gertrudis, three miles east; and the San Rafael, two miles north of the town. Even after some forty years of continuous development, the depth attained anywhere in the district is very moderate. The Real del Monte and Santa Gertrudis have gone down the furthest, and in no instance has the 2,000-ft level been passed.

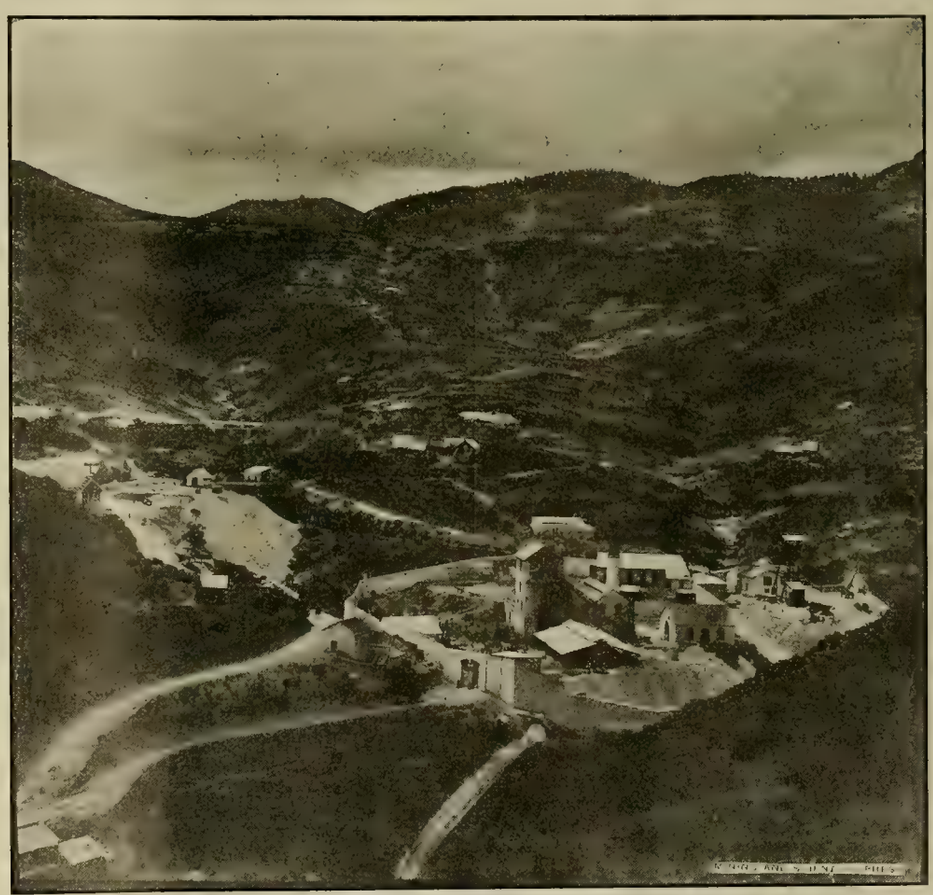
Recently the entire Real del Monte property, both in Real del Monte and also in Pachuca, changed from Mexican to American ownership, at a figure, it is stated, of $2,000,000, for the controlling interest. Such a sum is a moderate valuation for such an enormous area, comprising, as it does, some of the richest ground in Pachuca. The Barron claim, on the Santa Gertrudis vein, ought to be capable of returning the entire purchase price.

Water has been, and still is, the great difficulty in the working of the Real del Monte property. It is mostly pumped from the Difficultad shaft, where there has been installed for the last ten years a large compound pump, somewhat on the Cornish principle, although of German manufacture. The pump-column is some three to four feet in diameter, and the pump has a rating of five million gallons per 24 hours from a depth of about one thousand feet. This pump is now idle, having been superseded by a four-stage motor-driven centrifugal pump, which is now sending from 2,000 gal. per min. in the dry season to 2,400 gal. per min. in the wet season through a vertical height of 730 feet. The induction motor is of 750 h. p. at 900 rev. per min. This pump has proved a great success. In addition, an electrical centrifugal sinking-pump is hung in the shaft ready for any emergency. Speaking of pumps, one is reminded of the assertion that some of the early Cornish pumps at Pachuca cost their weight in silver to install, as there were no roads to speak of at that period, and all machinery had to be carried or dragged by mules from Vera Cruz, the port of entry. Some of these old Cornish pumps are still doing duty, and other large pumps of the same class have been installed within the last few years.

One notably hopeful feature of this district is the undeniable continuance of vein-enrichment to a moderate depth. The Difficultad and neighboring properties would appear no exception, for rich ore is said to be exposed in the bottom of these mines, at present under water. The Santa Gertrudis must have had some splendid ore in its upper levels, but it is doubtful whether any more valuable deposit, taking both value and width into consideration, has been encountered than is now exposed in their deepest workings. This favorable feature is not likely to continue indefinitely, but there is a large margin of depreciation before the ore becomes too impoverished to work, even at a great depth.

The San Rafael group represents the San Rafael, the Soledad to the west, and the Sorpresa to the east. This vein is one of the strongest in the district and has been remuneratively worked for many years. The present company, San Rafael y Anexas, is credited with 189 dividends, representing—at 40 pesos per month—about 18% interest on market valuation. The Soledad dividends exceed even this respectable figure by some 5%. The output was larger a few years back, when probably the ores were easier won than at present. The depth attained is moderate, and there is every assurance of successful exploitation in the future. This company is also using a modern high-duty electrical centrifugal pump for the unwatering of the mine. In addition, both ore-haulage and water-raising are assisted by a long crosscut driven from near the head of town and cutting the entire vein-system of that part of the district as far as the San Rafael properties. The adit is of respectable dimensions, well constructed and electrically lighted.

The Santa Gertrudis, as before mentioned, has the Amistad and Concordia on the deep of its vein. All are under one management, although run as separate companies; each company having the right to the profits on ore mined within its boundaries, the parent company receiving a percentage of the profit on all ore won on the deep of its vein. Immediately east of the Amistad the vein passes into the Barron claim—formerly a part of the Real del Monte property—and thence passing east enters La Blanca. There are no known developments of value east of the last mentioned. The dividend disbursements of Santa Gertrudis for the past thirty years have been phenomenal. Recently, the management reverted from its long run of Cornish managers to Mexican. Cornishmen have been closely identified with the Pachuca and Real del Monte camps ever since the inception of what might be termed "modern times," and the value of their service in the past it would be hard to overestimate. Pachuca has been the Calumet of Mexico. It would appear from the signs of the times as if others were about to assume "the white man's burden."



A REPRESENTATIVE MINE AT PACHUCA.

The workings on the Amistad property are approaching the 2,000-ft. level, but owing to difficulty with bad

*[Throughout this article Mexican currency is given in terms of pesos and centavos, therefore dollars and cents refer to American money only.—Editor.]

ground and excessive water, development has been slow. The deepest ore exposure is stated to be both wide and of good grade. With the metal in the ore to provide the necessary funds, there are many evident methods of conquering any difficulties that may be presented by either weak ground or abundance of water. There are two large Cornish pumping engines on this property, having 70 and 90-in. cylinders respectively; these combined should be capable of raising over two million gallons of water daily from the present depth. On the deep of the Amistad there is plenty of ground for many years, provided the vein continues remunerative.

La Blanca, as before stated, is on the eastern extension of this same vein, after traversing part of the Barron property. This has been worked for several years with a moderate output, and is today well developed in proportion to its output, which does not exceed 1,000 tons per week; which figure may be taken as about the limit of any Pachuca property of today—referring to the richer ores which are shipped to the smelter for treatment. A new shaft, the San Augustine, is now being sunk—and is down 250 meters—to relieve the pressure on the present main working shaft, the San Jose, and also to render available the upper portions of the mine workings that, at present, it is impossible to use, on account of both lack of ventilation and working facilities. This shaft will probably become available at the end of the present year, when an increased extraction may be expected. There is a large amount of ore that may be fairly considered blocked out between the 275 and 325-m. levels. The vein has been cut and a drift is being advanced on it at the 375-m. level, where the ore is wide and of fair value. As the Barron mine, to the west, is developed three levels below the present stoping ground in La Blanca, there is a considerable amount of ground thus exposed on two sides that may be reasonably reckoned to suffice for six or seven years. Between this part of the property and the southern boundary there are also fair prospects of encountering more ore.

As to the grade of ore and its nature. This vein carries $4 in gold per kilogram of silver. All ore carrying one kilogram silver is shipped to the smelter; below that grade, down to 600 grams, it is treated at local 'haciendas' by amalgamation, employing an improved patio process or some more modern form of pan-amalgamation. Speaking of this vein as a whole, breasts that are stoped for 30 ft. are not uncommon, and in some instances even 50 ft. The grade of ore in these wider parts is fully as rich as in the narrower, and wide stopes carrying three kilograms of silver, with corresponding gold values, are not unknown. The silver is present almost entirely as a sulphide—argentite. Native silver is so rare as to be a curiosity. The chloride of silver is practically unknown, and the arsenic and antimony compounds are negligible. The ore is thus a typical one for the patio, or allied processes, and would appear readily adaptable to cyanidation, since argentite is soluble in cyanide solutions, especially with the use of some accelerator or oxygen equivalent, like mercuric chloride. The grade of the ore, therefore, is the sole factor in determining the choice of treatment, that is, smelting or amalgamation.

One of the marked features underground is the amount of masonry used for the support of levels. 'Laterals' are unusual. The enormous pressure due to a weak hanging wall causes these arches of masonry to collapse, the pressure breaking the solid stone even when double-arched, that is, thirty inches thick. This masonry, seven feet high by six wide, is done under contract for 20 pesos per meter. Masonry is not employed in the stopes, a rude square set being preferred, although it is not dignified by that name; nor, on account of its symmetry of framed members, possessing the same advantages. All sets are close-filled with waste, mostly procured from crosscuts driven for that purpose.

The mills of Pachuca have been referred to. There are none at the mines, the ore being trammed or carted to the several haciendas in the town itself. Most mills employ an improved patio process or some modification of it. At the Progreso there is an installation of the Boss continuous process; at the Union a partial form of barrel chlorination is used. Other mills employ vanners more or less extensively, together with mechanical stirrers in the patio instead of mules to mix the charge. Presumably cyanidation will be tried on a suitable scale in the near future; and with the lower grade ore it will be a matter of some surprise if the introduction has not a marked success.

In most of the mills electrical drivage has been introduced; there are two companies that supply power. The combined output, however, is limited, and will not supply the Pachuca of the future. It is possible that the Mexico Light & Power Company, whose plant at Necaxa is readily available by constructing some thirty kilometers of line, may deem it advisable to enter Pachuca, and, should 10,000 h. p be required in this camp, there will not be the slightest difficulty and but little delay in that company proving equal to the occasion. With the advent of large quantities of cheap power, both the cost of mining and milling should be so lessened as to render a lower grade ore remunerative and prove an added factor in the rejuvenation and increased activity of the district. The Pachuca of the future will depend on deep mining, where hoisting and pumping play no mean part. Electrical energy for both functions is both efficient and cheap.

Tabulated Statement of Leading Pachuca Mines.

Name of Mine	Dividends to Date	Number of shares	Quotation Pesos	Market Value Pesos	Dividends Monthly Pesos	Return %
Amistad y Concordia ..	67	12,800	70	896,000	1	17.1
La Blanca	20	12,500	490	6,125,000	4	9.8
Real del Monte	254	2,554	1,600	4,086,400	10	7.5
San Rafael y Anexas ..	189	1,200	2,600	3,120,000	40	13.4
" " aviados ..	189	1,200	850	1,020,000	12	16.9
Santa Gertrudis	403	60,000	72	4,320,000	1	16.6
" " aviados	82	9,600	14	134,400		
Soledad.....	87	960	1,280	1,228,800	25	23.4

[The aviados correspond nearly to lessees.—Editor.]

The combined value on the open market of the three groups under review is therefore:

La Blanca	6,125,000 pesos
Santa Gertrudis y Anexas	5,359,400 "
San Rafael y Anexas	4,140,000 "
	15,624,400 pesos

Let us compare this valuation with the three leading mines of El Oro district, by way of estimation:

Name of Mine.	Shares.	Quotation—Pesos.	Market value—Pesos.	Dividends per annum—Pesos.	Return—per cent.
El Oro.....	1,080,000	12.50	13,500,000	1.50	12.0
Esperanza.....	455,000	45.00	20,475,000	10.00	22.0
Dos Estrellas...	3,000	10,000.00	30,000,000	720.00	7.2
			63,975,000		

[The peso or Mexican dollar is worth 50 cents U. S.—Editor.]

The three Pachuca mines are, therefore, apparently considered in the eyes of the investor as but equal in value to one quarter of the three mines at El Oro. Just how this valuation is arrived at, it is difficult to see. It is true the Pachuca properties are much older producers than those at El Oro, but, unless developments at El Oro prove ore in depth, those of Pachuca will be working many years after the former are worked out, with the possible exception of the Dos Estrellas, which has a future, and probably can supply sufficient ore for its 230 stamps for ten or twelve years.

The Pachuca mines are controlled by Mexican companies with Mexican shareholders, while the mines of El Oro are held in America, England and France, where a very much lower rate of interest is considered adequate return from a mining investment. The local investor, however, is free to draw his own inferences.

Taking a broad view of the entire Pachuca district and considering the methods in vogue, it must be confessed that one is not a little surprised to find so little real activity over such a wide area. On most of the properties, little or nothing appears to be doing. On those that are at work, the output appears from one-half to one-quarter of what the properties are really capable. The camp as a whole is credited with an annual return of 6,000,000 oz. silver and 30,000 oz. gold, having a total of $4,500,000. The methods employed both underground and at surface are antiquated. Pachuca, with the exception of some electrical drivage, cannot be considered as up-to-date in any way. Its methods are slow and its output small. It resembles a giant in possibilities, but a dismally lethargic one. The Cornish pump, cart haulage, hand breaking, small output, old methods of treatment, steam power, all must go and make room for modern installations and practice.

In the Rainy river district in western Ontario, gold occurs in a mass of rock described in the Government reports of the Province as consisting of a mixture of altered granite, quartz and chlorite, with streaks of green schist. It has been traced three or four miles, and has a general direction of northeast and southwest. The boundaries are rather indefinite, but as near as can be ascertained it is 462 ft. wide at the widest known place. On one location it varies in width from 100 to 200 ft. One hundred feet is its width at the narrowest place, as far as known. It is stated that from careful tests which have been made, much of this rock-matter contains $1.50 per ton in free-milling gold. It has not been found possible, however, to work it at a profit.

Crude Oil vs. Steam.

Written for the Mining and Scientific Press by
William Magenau

Oil and gas internal-combustion engines have found a wide application in regions remote from coalfields or scantily supplied with water, but it will be a surprise to many to learn of the saving over steam-power effected by using crude oil in this type of engine in a locality where the cost of coal is not excessive, and the nearest oil wells 1,000 miles distant.

Such an instance may be found in the custom lead-smelting plant of the Luna Lead Co., at Deming, New Mexico, under my superintendence. This plant has been supplied with power by three Hornsby-Akroyd oil engines of 25-brake horsepower each, made by the De La Vergne Machine Co. of New York. The engine is built to run on kerosene or the higher grades of crude oil, that is, those with paraffin base, as are found at Beaumont, Texas, and in Pennsylvania. The California oil is not suitable, as it contains much bitumen.

To illustrate the saving over a steam-plant, the following tabulation is presented. The basis of equipment is the continuous delivery (24 hours daily) of 40-brake horsepower:

I. COST OF PLANT.

Steam.

Two 11 by 14-in. automatic cut-off steam engines f. o. b. Deming, N. M. (To be run alternately).	$1,161.68
One 48 by 16-ft. return tubular boiler f. o. b. Deming	539.52
Brick and all material for setting	292.30
Concrete foundations for engines and boiler	150.00
Labor of erecting	200.00
	$2,343.50

Crude Oil.

Three 14½ by 17-in. oil engines f. o. b., Deming, N. M. (To be run two at a time).	$4,725.00
One storage tank for oil 13,000-gal. capacity	500.00
Concrete foundations	150.00
Belt of extra engine	50.00
Labor of erecting	100.00
	$5,525.00

II. COST OF OPERATION.

Steam.

Coal Consumption on 1,200 h. p. hr. per 24 hr. (50 i. h. p. to produce 40-brake h. p.) at 5 lb. per h. p. hr. 6,000 lb. at $5 per ton	$15.00
Attendance	
2 engine tenders (12 hr. shift)	8.00
2 boiler-men	3.00
Oil, waste, and supplies other than fuel	0.20
Repairs	0.20
Interest on power plant at 5%	0.30
Cost per 24 hr.	$26.70

Crude Oil.

Crude oil consumption 106 gal. per 24 hr. (actual results) at 2½c. per gal. (in tank car-lots)	$ 2.65
Attendance	
2 engine tenders (12 hr. shift)	8.00
1 helper (1 shift only)	1.50
Oil, waste, and supplies other than fuel	0.20
Repairs	0.60
Interest on power plant at 5%	0.71
Cost per 24 hr.	$13.66

The saving per day of crude oil over steam is $13.04, amounting, in a working year of 350 days, to $4,564, which is $1,400 more than the extra cost of the oil-engine plant.

Cost of oil engine power per brake horsepower per year of 350 day (24 hr. each)	$119.53
Cost of steam power per brake horsepower per year of 350 days (24 hr. each)	233,63

A comparison between steam and oil plants of larger capacity, say, from 100 to 500 h.p. and upward will be less favorable to oil in the chief item of fuel cost, as on such large steam-plants a duty of two or three pounds coal (in this case a good quality of bituminous mined in New Mexico) per horsepower hour could be had. The matter of attendance would be in favor of the large oil-engines. Boiler attendance increases with the size, unless automatic feeds and coal-handling devices are used, and in that case the cost of such appliances and their operation is far more than the cost of handling oil, which is scarcely more for a large plant than a small.

It is not intended here to discuss the matter in all its applications, but merely to give figures from actual experience with small units. It will be noted how closely the actual oil consumption checked the figure found by the engine builders in a 30-minute test-run at their works before the engines were sent out. They reported a consumption of 0.9 lb. Beaumont crude oil per brake horsepower hour, running the engine on full load (25 h.p.). As 0.9 lb. is equivalent to 0.115 gal., and as our plant requires 40 brake h.p., this would figure out to a consumption of 110.4 gal. per 24 hr., whereas the actual daily consumption over several months was 106 gallons.

The engine operates without any accessory carburettors or other appliances for vaporizing the oil, the same being sprayed into the hemispherical head of the cylinder which is kept red hot by the explosions which give the piston its impetus. No trouble is experienced with ignition, as is often the case with electric sparkers or heated tubes on gasoline engines, and the crude oil is completely consumed except for a slight deposit of carbon which clings to the walls of the vaporizer head. The necessity for cleaning this out every 36 or 48 hours (the work of a quarter-hour) requires an extra engine for such service as smelting, where no interruption is permissible; but such extra engine would be installed in any case, as is done in steam-plants to provide against break-downs. In a pinch the plant could run with two oil-engines, allowing 15 minutes each day for partial shut-down in order to clean out one engine.

We had some difficulty with these engines while employing engine tenders not fitted for the work, and I would strongly counsel anyone installing such a plant to employ at least one first-class mechanic versed in oil engines, notwithstanding manufacturers' statements to the effect that a Mexican farm-hand can run them. Since competent men have handled this installation, reliable and cheap power has been the result.

Gold Mining in Egypt.

In a recent Bulletin of the Institution of Mining & Metallurgy, London, Ernest H. S. Sampson describes the ancient mine workings of Atallah in Upper Egypt. He says that the quartz varies in color from pure white through various shades of blue to almost black, and contains galena, pyrite, and blende. The percentage of silver remains fairly constant, notwithstanding the fact that the gold content varies from a few pennyweights up to as much as 14 or 15 oz. to the ton of 2,240 lb. The quantity of base metal visible to the naked eye affords, as a rule, an excellent criterion of the amount of gold in the ore.

Fairly conclusive proofs that the mines were hurriedly abandoned by the ancients, owing probably to an unsettled state of affairs in the government of the country at that period, are to be found in the form of small piles of rich quartz left on the floors of some of the stopes, and also in the fact that some of the working faces had been left absolutely untouched after the fire-setting was actually completed. There is abundant evidence that fire-setting was the chief method employed for the disintegration of the quartz. The hanging, and sometimes the foot-wall, of the veins is in most places blackened by the smoke from the brush-wood fires, and charcoal may be found in considerable quantities in many instances where the workings have not been filled with sand and rubble. The only tools so far discovered are two almost perfect specimens of iron picks (very similar in design to the modern miner's pick) and, probably more ancient than these, a stone implement in the nature of an ax-head, identical in shape with a specimen that was found near Kimberley in the early days of the diamond-fields. Numerous stone hammers also were found; these may or may not have been contemporaneous with the iron tools above mentioned. Two classes of stone grinding mills were also found in considerable numbers, while at the Eridea mine a few months ago, a wooden scraper was discovered, shaped something after the fashion of a Dutch hoe, the blade being about 10 in. long by 4 in. wide, and semicircular in shape, and the handle two feet long. In the old workings at Atallah some wooden props were found, evidently placed in position with the intention of supporting the roof. The wood was a hard variety of acacia similar to that growing in the wadies at the present day, and was still in a perfect state of preservation, notwithstanding the fact that it had probably done duty for 2,000 years. In the same stope were also some stone supports arranged after the manner of the monoliths at Stonehenge, that is, two upright slabs supporting what is technically called a cap or head-tree.

An Authoritative Opinion.

By John C. Branner.

During the past week Mr. John C. Branner, professor of geology in Stanford University, delivered an address at San Jose. Among other things, he said:

Ever since I have been in California I have been making a study of the geology of the Santa Cruz range of mountains. The work of mapping out the fault which lies along its surface was completed about six weeks ago. Immediately after the earthquake I went out to see if these fault lines had been doing any business. I found, as I expected, that they had.

Where we had located the line on the map was a great furrow, marking the line of the disturbance. Roads were pushed out of their places, pipes were broken fences were disarranged, and the surface of the earth was broken up on the summit of the range along the full extent of the fault line, and all of the manifestations of a violent character were within a very short distance of the line.

This fault begins a short distance south of San Francisco. That city is not along the line of the fracture, as it enters the ocean near Mussel Rock. From there it runs over the mountain, through San Andreas lake, through Crystal Springs lake, through the village of Woodside, over Black mountain, along Stevens Creek canyon, across Campbell creek two miles above Saratoga, through Wright's station and Skyland. Along this course we traced the disturbance and it was marked in a perfectly distinct way.

It showed a lateral displacement of at least eight and a half feet. There was no vertical displacement. Of this movement there were evidences in great abundance. Near the coast a road is broken and thrown out several feet. At Woodside a six-foot displacement was noted. A water pipe was broken in two and the ends are seventy-three inches apart. A fence has been offset eight feet. At another point a fence was jammed together the length of a panel. Some water pipes were found which were telescoped. Near Woodside the fault ran under a big oak tree, which was uprooted. In Stevens Creek canyon were landslides without number. Near Skyland a house was broken in two.

The greatest effect of the slipping of the fault was noticed in the trees. The houses did not seem to be much more badly damaged there than they are in the valley; but limbs of trees were snapped off. Trees were uprooted. On the other side of Loma Prieta, along the line of the fault, the forest looked as though a swath had been cut through it two hundred feet in width.

At Black mountain I found beside the main fault, which ran through the mountain, a sort of branch. Following this the whole side of the mountain seemed to be shattered as though it had been picked up and allowed to drop. In a little over a mile I counted no less than 345 cracks running in every conceivable direction.

I am sure that the slippage of the fracture was at least eight or nine feet. The fault was an old one. All the large surface stones had been previously broken up. The soil was deep and was not in a condition to show the full extent of the movement.

Although I have not made a personal examination of the territory north of San Francisco, I am sure the same fault extends to that region. After leaving the coast it follows the bed of the ocean to Bolinas bay, to Tomales bay, then to Fort Ross, over the hill to the bed of the Wallala river and the Garcia river, thence to a point near Manchester, where it enters the ocean again. This is undoubtedly responsible for the great disturbance in that region.

Some people are surprised that there was no tidal wave overwhelming Santa Cruz. Many expected to see one coming up the Santa Clara valley from San Francisco bay. The explanation of this is simple. The movement was lateral and could not cause a wave. If a vertical movement of the same extent had come there would certainly have been a wave of probably considerable size. There need be no fear, however, that San Jose will ever be overwhelmed by one. The configuration of the bay is such that it could not get here; at least until the people had time to get safely out of its way.

As to the cause of the pressure which produced this slipping there are three theories. I will give them to you and let you take your choice. The first is that the increase of temperature in the earth, gradually coming toward the surface, has caused an expansion of the rock and a consequent pressure outward. The second is that rocks which were hot have become cooler and contracted, producing a strain in the other direction. The third is that the shifting of the load on top of the earth produces the pressure.

It is as though Mt. Hamilton were transferred to the Santa Cruz mountains. The shifting is not accomplished in this way, of course, but it is continually going on by the streams carrying sand and mud from one section to another.

The question is sometimes asked seriously whether the weather has anything to do with causing earthquakes. The question has been given serious consideration. Scientists have made lists of all earthquakes that have been known, have tabulated them, have noted the phases of the moon, have taken into consideration the weather condition. Their conclusion is that if there is an earthquake just ready to go off, a change in barometric pressure may start it. But it is not possible to conceive of an earthquake being created by weather of any sort.

It was expected when I was invited here, of course, that I would soothe your troubled spirits and explain away all possibility of a repetition of the shock of a month ago. Well, I shall leave prophecy to the prophets. That is not in my line. I cannot tell whether there will be another earthquake or not.

My confidence, however, is based on this fact. The rocks forming the crust of the earth on the coast have been broken up so by the past disturbances that no great strain can accumulate. The faults slip more easily than if they were two masses of solid stone pressing against each other. Our hope is that the little earthquakes may continue. They relieve the strain, and do not give an opportunity for any great pressure to develop.

So far as this matter is concerned, however, there is no part of the world that has any assurance that it will be free from temblors. Missouri had a very severe earthquake a great many years ago, and yet if scientists had been asked to pick out a section that would probably be free from earthquakes, that would likely have been the spot they would have settled on. So much for prophecy. I feel safe in saying, though, that California will probably never experience any violently destructive shock, and for the reason I have mentioned. So far as California is concerned, I would rather live here with its earthquakes than anywhere else without.

Cheap Mining.—Mine superintendents sometimes receive more credit for cheap mining than they are really entitled to. In one instance a new superintendent finds the property without ore, but with a large amount of deadwork done. He continues the work a short time and develops payable ore. This at once distinguishes him as a capable miner and good manager. In another instance the superintendent develops a good orebody, discontinues development work, thus cutting down expenses, while producing good results at minimum cost. He goes to another locality and leaves an exhausted mine for his successor, who must find more ore, if he can, at the expense of profits previously made. The owners, if not practical people, naturally make a comparison between these men to the disadvantage of the new man. They tolerate him, possibly until the expiration of the term of his contract, during which time he has vigorously carried on deadwork. They then offer extraordinary inducements to the former superintendent to return, which he does, and finds the mine in such a condition that it proves no hardship to place it quickly on a paying basis once more—at the expense of the reputation of the man whom he has just succeeded. A superintendent may gouge a mine taking out ore at low cost and apparently leaving a large amount of ore in sight but he may have carried on his work in such a way that this ore can only be reached at great expense, or it cannot be mined at all at a profit by reason of the previous application of improper mining methods. The cheapest mining is that which permits the extraction of the ore at a minimum of expense, and at the same time makes available an amount equal, at least, to that removed, until the mine is exhausted. Makeshift, and short-sighted methods, which take no heed of the morrow, cannot in the end give the most satisfactory results.

Korea.—The mineral output of Korea is principally gold, recovered both by placer and quartz mining, with over 120 workings, and an annual production of about $2,250,000. Placer gold represents 66 per cent of the total. There are silver deposits but only experimental workings have been made. Copper is found mostly in the northern and southern portions of the peninsula. The Kapsan mine is producing some 270,000 pounds of refined copper per annum. Iron is found in several provinces but the expenses of mining and smelting have retarded the exploitation. There are some coal deposits at Pyeng-Yang consisting of smokeless coal, and the others of rather inferior bituminous. Excellent crystal is found in north Kyeng-Seng, and is a famous product of Korea.

Gold Veins in Granite in California.

Written for the MINING AND SCIENTIFIC PRESS by
W. H. STORMS

The gold-bearing veins occurring in granite in California have distinct characteristics, and are in many respects unlike the veins found in stratified rocks, though resembling, somewhat, those occurring in other massive rocks.

The largest areas of granite in this State are those in the Sierra Nevada, but there are other granitic exposures in the Coast range, and in the desert country south of the Tehachapi mountains. Whenever veins are found in these granitic rocks, they possess many structural features in common, and to such an extent are these peculiar conditions similar that it may be concluded that they are due to the fact of their occurrence in a rock of almost identical character, whether in the Sierra, or in an isolated desert mountain.

In these several granitic areas are found a large number of veins. Some of them appear to be entirely independent of all others, though in many instances there are found systems of connected fissures, produced by the same cause and having many things in common. It has been remarked that the minerals occurring in these veins in granite are similar throughout the State, and it has been further observed that they differ materially in this respect from the veins found in the andesites, diorites, quartz-porphyries and other massive rocks, whether these rocks occur in the vicinity of the granites or at a great distance from them.

In some instances veins pass from granite into greenstone or slaty rocks. Wherever this occurs, there is a distinct difference between the veins, not only in their structural features, but in the ore.

There is no uniformity in the strike and dip of veins in the granite. They strike in various directions, even in the same district and in the same vicinity. In several districts there occurs a main fissure, usually large and well-defined and of relatively great continuity, from which branching veins extend outward at an angle of 30 to 45°, sometimes on one side, more often on both sides of the main fissure. Occasionally these branching veins cross the main fissure, but as often their continuity is interrupted by it, though, at some distance from the point of intersection, a vein will be found branching from the opposite side of the principal fissure.

In some instances it might be thought that the cross-fissures were the older and had been cut by the larger fissure, with a displacement by faulting along the plane of the more recent vein. The structural condition of the veins at the point of branching, however, does not bear out this theory in any instance which has come under my notice.

The dip of these veins is no more regular than their strike. In the veins occurring in slaty and schistose rocks, the strike and dip usually conform with those of the inclosing rocks, or nearly so, and in the foothill region of the Sierra Nevada, this strike is almost uniformly a few degrees west of north, with a dip to the eastward, varying from 30 to 90°, but usually between 45 and 65°. The veins in granite strike indiscriminately in any direction, dipping in the same erratic manner, and frequently changing dip, rendering economical development a puzzling problem to the mine manager, who, to avoid losing his vein, usually follows it wherever it may lead him until he has measured the inconstancies of dip and determined where it will be most advantageous to sink a new shaft at a uniform angle. It is nothing uncommon for a vein in granite to dip in quite another direction in depth from that near the surface, and in some instances these changes of dip are numerous. These fissures are found occurring singly and in pairs, and in many places, as zones of fracture of varying width, comprising several fissures having an approximate parallelism. Not infrequently these fissures, both those occurring singly and those of multiple fracture, are planes of movement. This is evidenced by the striations on the walls, and by the polished surfaces, gouge and seams of clay. In many cases these zones of fracture are found to consist of crushed granitic material, much altered, and in some instances containing vein-quartz in a granulated condition, indicating that the movement of the rock-masses had again occurred or continued long after the original deposition of the silica in the zone of fracture and crushing. The occurrence of polished faces on planes within the vein itself is another evidence of this. In more rare cases, veins have been fractured by movement of the walls and silica, infiltrating, has recemented the angular fragments, forming a brecciated vein. It is strange, however, that only rarely are veins of this type payable. They usually contain gold and sulphides, but not enough to constitute a profitable mining proposition.

In the zones of crushing, the feldspars are invariably kaolinized, and the bi-silicates are altered to chlorite and other secondary products. The whole mass is soft, and when wet, often mushy, and dangerous to mine, requiring prompt and close support. This soft, decomposed, granitic mass usually contains iron sulphide and gold, but is generally too low-grade to constitute profitable ore.

In these same fissure-planes or zones are found the concentrated mineral deposits commonly called 'ore-shoots.' In extent they vary greatly, from short bodies less than a rod in length to those several hundred feet long. Where small shoots occur it is not uncommon to find them succeeding each other at short distances, forming practically a continuous run of ore two hundred to three hundred feet long, or even much longer.

The ore-shoots usually lie to one side of the crushed zone; sometimes there is soft material on both sides of it. In other instances the pay mineral is separated from the zone of fracture and alteration by a strip of hard granite, indicating the periods of mineralization, only one of which resulted in the formation of ore. Occasionally the ore-shoots are distinctly separate, succeeding each other at greater or less distances, and connected by nothing more definite than a clay seam of knife-blade thinness. Large masses of quartz occur, ten to twenty feet wide, white, partly crystallized and showing beautiful structure, with clean walls, but almost destitute of gold or silver minerals, and but little sulphide, and that low grade. In some instances, a large quartz vein of this description will be found accompanied by a small pay-streak of rich pyrite, but more commonly the richer ore is found in separate shoots, filling the fissure in which it occurs, from wall to wall, and not infrequently the richest ore is found in veins branching out from the larger vein, as above described. There are several instances of this character in Tuolumne county, near Soulsbyville and Carters.

That these veins are the result of the substitution of silica, calcite, and other minerals for the more soluble portions of the crushed granitic mass there seems no reason to doubt. These vein minerals have been conveyed to their point of deposition by mineral solutions, probably issuing from a deep-seated source. The most complete replacement has taken place where the fissuring and crushing of the original granite has been complete. The vein quartz is found exhibiting every phase of condition from a partial alteration of the granitic minerals to a complete substitution of silica, calcite, pyrite, pyrrhotite, and other sulphides, for the altered granitic mass. Even rock that is almost normal granite in appearance, will carry payable gold and auriferous sulphides. This will occur both within the vein and in the wall-rock adjacent to the fissure, proving that the mineral solutions which deposited the sulphides and precious metals in the vein were not confined wholly within the limits of the fissure, but also penetrated the adjoining rock to a distance of a foot or more. It will be understood that where these minerals occur in hard, apparently normal granite, close inspection of such gold-bearing rock will show it to be altered. The quartz grains may appear normal, and doubtless are, but the feldspars will be found white and opaque; finely disseminated pyrite is always present, and in many instances galena will also be present. The appearance of galena, though not without exception, is generally an indication of gold, whether within the vein or in the wall-rock.

In the silicification of these zones of crushed granite every phase of alteration is noticeable, from that wherein the presence of foreign quartz is scarcely observable, through every stage of transition, to the most complete alteration to crystalline quartz. Calcite is of common occurrence, and quartz crystals are frequently found.

A characteristic occurrence in these veins is that of a brilliant iron sulphide appearing in groups of fine crystal aggregates, often tarnished and iridescent, forming beautiful cabinet specimens. So characteristic are these occurrences that it is often difficult to distinguish ores of this kind in one granite district from those of similar kind in another district many miles distant, and possibly in another granitic area. Pyrrhotite is another characteristic mineral. Mispickel, galena, zinc-blende, chalcopyrite, pyrite are abundant and occasionally telluride minerals are seen. In some localities the vein quartz is normally fine-grained and flint-like, but it is often found crushed to a sugar-like condition, as white as snow and containing little if any sulphide mineral. The flinty, hard masses, occurring as a nucleus of the white granulated rock, sometimes show faint bluish stains and, more rarely, the minute dark flakes of a telluride mineral. Such rock not infrequently also shows free gold, and assays well; but owing to its limited occurrence it is likely to prove disappointing. Of the many varieties and conditions of ore found in these veins in granite the most satisfactory is the heavy sulphide ore, generally containing twenty to sixty per cent sulphides and assaying from $20 to over $100 per ton. In some mines, ore of this character runs from $200 to $500 per ton. When concentrated, the sulphides are usually high grade, occasionally running up to $1000 per ton. Some of the mispickel ores are rich and in a few instances the zinc-blende is found to carry large amounts of silver or gold, and usually both. Again, the quartz ore—in granite—containing pyrite only is high grade, as compared with the ores of the slate and greenstone belts.

Although the veins vary greatly as to width, there is nothing approaching a constant ratio between size and value. The wide vein may be rich and the narrow vein poor, and vice versa, but ordinarily the smaller veins are the richest. Nor can the physical appearance of the ore always be depended upon as an index of value, for the pieces broken in different mines may look much alike, but differ greatly in value. Pyrrhotite and mispickel are the most characteristic minerals of veins in the granitic areas, the former being particularly abundant in the larger orebodies, and the latter in the smaller veins.

Ore-shoots often overlap at their ends, being apparently in a chain of fissures following a general direction, and connected by small crossing seams or fissures, though these latter are obscure. Occasionally two veins may be seen approximately parallel, but separated by a strip of much-altered granite, one to four feet wide. In both strike and dip these veins will, in some instances, be found to unite, forming a single vein, only to part again further on and possibly to send other off-shoots, or branches, into the walls. This condition would suggest the formation of a system of intimately connected fissures, produced at the same time and by the same cause. This branching tendency is one of the most pronounced characteristics of the veins in granite in California.

Usually one wall is better defined than the other, generally the foot-wall, the zone of fracture extending into the hanging-wall granite, to varying distances. Sometimes the line of demarkation between vein and wall is sharp and clearly defined, though there may be no gouge, selvage or seam between the two rock-masses; each presents its own peculiar physical characteristics; the vein being, in the phraseology of the miner, 'frozen.' In other cases a clean well-marked hanging wall may be seen which gradually diverges from the foot, the vein practically filling the zone from wall to wall. Where the space between these walls is narrowest, the vein is likely to consist of solid well-mineralized quartz, but as the distance between the walls increases, the vein material gradually takes on the granulated appearance of the granite; mineralized portions of the altered granite itself may be found, though there may be masses and reticulations of solid sulphide ore mixed with this otherwise unpromising material. When the grade of the best ore is high, this granitic vein-filling is also likely to be payable.

When the two walls have diverged four to six feet, another interior slip is found forming a second hanging wall a foot or less from the foot-wall, which diverges in the same manner as before, and this in turn is succeeded by a third, and so on throughout the length of what may be considered the pay-shoot, which in this instance is made up of a succession of irregular wedge-shaped orebodies.

Large veins, well defined, and mineralized will gradually become smaller, finally pinching out and disappearing in a few small seams that are lost in the country rock. When this occurs, if the mine workings are driven straight ahead, another lens or orebody is likely to be encountered, or, if not appearing in the drift, judicious cross-cutting will usually discover it, offset to one side. If to the left, the next shoot is also likely to be to the left. The characteristics described as occurring longitudinally in these veins, may to a great extent be anticipated in following the vein on its downward course also.

At many of the mines occurring in granite it is the custom to sort out what is considered waste from the recognized ore. Where the payable ore is clean quartz with or without sulphide mineral, this may be done to advantage, but when the quartz ore becomes much mixed with the partly altered granite, sorting cannot be practiced so effectively, and instances are known where the richest ore was the decomposed granite, the quartz containing more mineral but less free gold. It is not an uncommon thing to see coarse gold in the granite of the vein proper and also in the walls at a distance of a foot or more from the walls. This must be watched closely by the miner or rich ore will go to the dump. The fact that several old granitic dumps at California mines have been profitably sorted and milled is sufficient proof that such care was not always observed.

The Evolution of a Mineral Vein.

Written for the MINING AND SCIENTIFIC PRESS by ARTHUR LAKES.

It has been suggested recently, by D. W. Brunton, that in large mines a mining geologist should be employed whose business should be to keep track of the development by making maps and sections of the geological features of the vein as they are brought to light by exploration. Being engaged for some weeks at a small mine in Idaho, I endeavored to carry out this suggestion when observing the behavior of a vein in the face of the drifts, winzes, and raises, as exposed after each shift, and making drawings of them when there was any notable change. Sketching the vein constantly and recording the date of each sketch with the distance from one observation to another, appeared to throw some light on the essential character of the vein formation.

Many so-called veins are mineralized zones rather than individual veins; in this case, the zone lay in a series of thin layers of contorted limestone, with some slaty and quartzitic beds. The bodies of ore and vein-matter occurred in lenticular form, alternately widening and pinching. When the lateral crumpling formed a concave or hollow fold, the vein-matter was liable to occur in its lap, and when, by the same force, the strata bulged ,there was a corresponding pinch.

The vein-matter and ore were within a zone of slip-planes, due to compressive forces corrugating the strata and causing the pliable sheets of rock to slide over one another like the leaves of an unbound book when crushed in the hand. Each sheet of rock, as it slid past its neighbor, polished, grooved, or striated it, and was correspondingly polished and striated in turn. Striation lines showed the general direction of the forces exerted and the movement of the strata, which might be even in opposite directions. In a neighboring mine two sets of striation lines were found crossing one another diagonally on the same hand-specimen surface is coated by graphite, shining like a polished steel plate and crossed by both straight and contorted grooves, and striation lines. Fig. 1 gives a general idea of the vein-zone. A represents the hanging wall of thinly bedded black limestone, which is sheeted by slip-planes. B is a lenticular body of breccia four to six inches thick and, like that of Fig. 4, cemented by graphitic matter and impregnated with iron pyrite. some galena and some zinc-blende, yielding at times a fair body of ore. C is an adjoining zone, a few inches wide, of a soft, oxidized character and reddish, banded appearance, containing thin seams of crystalline quartz and some galena. The ore may be a replacement of the crushed rock. Its banded structure suggests infiltration of mineral solutions. D is a zone, two to three feet wide, of brecciated silicious limestone. This is followed by E, a persistent belt of black, slaty matter, barren of ore, and giving no reactions with acid, locally

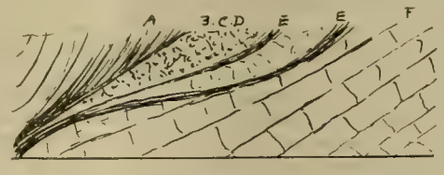


FIG. 3.

called the "foot-wall band," which in subsequent developments grew nearer and nearer to the hanging-wall zone until it split up and merged in it. Fig. 2 shows the beginning of a fault in the foot-wall band, which was acentuated a few feet further. Such faulting and disturbance generally presaged ore. With the final merging of the foot-wall band with the hanging-wall zone, and an accompanying flattening in dip, there came an increase of quartz, ore and vein-matter, and a union in the vein which led, shortly after the condition represented in Fig. 3, to the discovery of a lens three

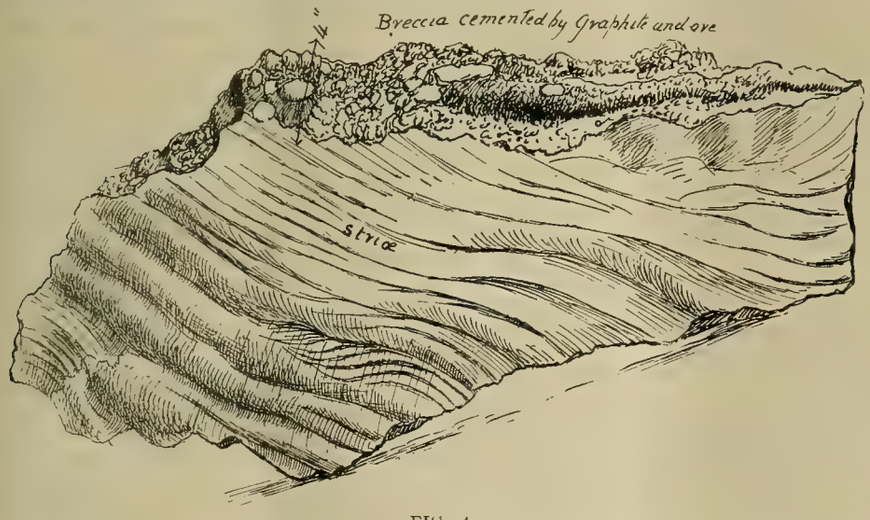

FIG. 4.

of polished mineral, showing that beside the original movements that made the fissures, there were later ones disturbing the ore by forces exerted at different times and in opposite directions. A gouge, black with graphite or other carbonaceous matter, coated the surface of the slip-planes, and the lenticular space between them was occupied by crushed fragments of wall-rock cemented by gouge, quartz and ore. Ore was likely to be found when buckling was most pronounced and when the strata were most disturbed, as evidenced by crushed rock and the appearance of little faults, also when the dip flattened and when quartz and black graphitic matter were abundant. The principal zone for ore was near the hanging wall, where these conditions most prevailed. In the movement of the strata, two or three curved slip-planes, inclosing narrow lenses of vein-matter, might overlap one another. Next to the hanging-wall zone there was a body of breccia, two or three feet wide, followed by a belt, called by the miners the "foot-wall black band," because it lay next to the so-called foot-wall and was composed of a light gray silicious limestone, as compared to the dark limestone of the hanging.

In the accompanying sketches, Fig. 4 shows the section of a lens taken out bodily between two slip-planes close to the hanging wall. The ore and breccia are cemented by a black filling. The lens is about four inches in greatest diameter, tapering each way; its feet wide and ten feet long of solid galena. This pocket was, however, quickly followed by a corresponding pinch.

To Determine Arsenic in Presence of Vanadium and Molybdenum.—To every one gram of the substance are added 1½ gm. of potassium iodide and 70 c.c. of hydrochloric acid (sp. gr. 1.16) and the mixture is distilled at once, without waiting for solution. A 100 c.c. distillation flask with a well-fitting ground-in delivery tube is employed, and in order to avoid liquid being thrown over, the neck of the flask is enlarged at two points. The receiver is cooled by water to prevent loss of arsenic. Much iodine separates at first and until all this is over, the flame should be carefully regulated to prevent stoppage of the delivery tube. All the arsenic is distilled over in 20 min. The distillate is evaporated to a syrup, chlorine water being added at intervals as an oxidizer. The arsenic pentoxide may then be weighed as such, over phosphorus pentoxide, after evaporation in a platinum dish and heating to dull redness (435° to 450°), or be precipitated by magnesia mixture. The vanadium and molybdenum in the residue are separated, as usual, by sulphureted hydrogen, the former being determined and volumetrically by permanganate and the latter as trioxide, according to the known methods.—Journal of the Society of Chemical Industry.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each quest on. No assays are made.

The three samples from Contact, Nevada, marked W. F. K., are all consolidated volcanic ash, commonly known as tuff.

The rock from Wolton, Wyo., is a basic eruptive rock —Norite. It belongs to that class of intrusives described by J. D. Irving as 'luster-mottled rocks,' occurring in the Lake Superior region.

The rock from Boise, Idaho, marked Snake River plains, is Calcareous Travertine,—calcium carbonate deposited from springs. Rock of this character makes superior lime, and when mixed with the proper amount of clean clay makes excellent hydraulic cement.

The mineral from Columbia, Arizona, marked C. W. N., is principally Cerussite (lead carbonate). The brown portion is principally iron oxide, and the light green spots contain a little copper carbonate.

The mineral sample from Robinson, Utah, is a hydro-carbon, and may be considered as one of the varieties of Elaterite, which it most resembles. Gilsonite is hard, brittle and looks much like pitch. Grahamite resembles Gilsonite. 'The Prospector' makes no analyses.

The rocks from Coarse Gold, Cal., are: No. 1, Quartz, in which is enclosed Garnet, and a little Epidote (the greenish portion; No. 2, Limonite (iron oxide). It may be the gossan of a vein, though this cannot always

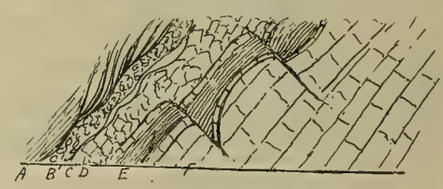

FIG. 2.

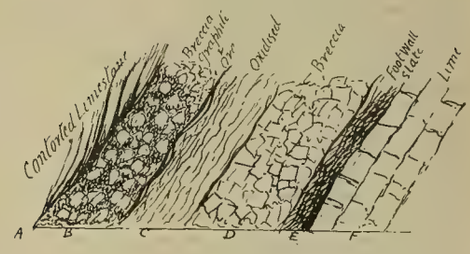

FIG. 1.

be told positively from the hand specimen, for ferruginous springs frequently deposit iron oxide which in time may become consolidated into a hard ore. Bog iron ore deposited in lake beds also is similar in appearance.

The New Standard Concentrator.—Concentration of ores is one of the most important of metallurgical operations, for upon the successful application of concentration often depends the success of the mine, and the machine which can accomplish this is in demand. The latest mechanical device introduced for the purpose of mechanical concentration of ore is the New Standard concentrator. This machine is larger than most table concentrators, and is claimed by the manufacturers to be therefore superior to machines of less superficial area. It combines the well-known, and successfully long-applied, bumping-table principle, with the low riffles, adjustable grade, and cross flow of water, that are important features of some other concentrating machines.. The New Standard is hung from a substantial timber frame, therein differing from most other machines which are supported by uprights from below. The makers claim for it, large capacity and clean concentrate—desirable features in every concentrating machine. It is manufactured by the New Standard Concentrator Company, 602 North Main St., Los Angeles.

Special Correspondence.

LONDON, May 9.

At the annual meeting of the Great Boulder Proprietary Gold Mines, Ltd., held last week, the chairman, Mr. G. P. Doolette, had a highly satisfactory report to give. In the course of his speech he pointed out that although the annual returns for 1905 are somewhat less than they were in 1904, the extensive developments more than counterbalance the shortage which is shown in the returns, and never in its history had the Company been able to record such material prosperity. The developments for the year added 206,535 tons, containing 172,523 oz. gold, to the reserves, which, after deducting the ore milled for the year, namely, 132,052 tons, show an actual increase of over 75,000 tons, the total reserves at the end of the year being 453,649 tons, containing 456,379 oz. fine gold, having a money value of £1,893,800, thus, the chairman remarked, establishing the Great Boulder Proprietary company's shares as a gilt-edged security amongst mining investments. The output for 11 years has been nearly 4½ millions sterling, and nearly half of this amount has been distributed to the shareholders by way of dividends. During 1905 they had a large capital expenditure of over £50,000, which came out of revenue without interfering with the regular dividends, the benefit of which the shareholders were having at present, and will have as time goes on. One of the satisfactory features in connection with the development was that the average value of the ore is well maintained (being 1.12 oz.), and that the return from the ore treated is kept well within this value. It was an accident that the returns for 1905 are somewhat lower than those of 1904, and consequently that the profit had not been so great; but all the same it was satisfactory that on the year's working the handsome profit of £320,258 had been made, which not only enabled them to maintain the regular quarterly dividends, and to provide for the capital expenditure in the equipment of the Hamilton shaft, and the addition of accessories to the mill for the reduction of costs, but also to pass to the reserve fund the sum of £35,000, bringing that fund up to £160,000. Referring to the working expenses, the chairman said: Another satisfactory feature of the work for the year had been the appreciable reduction in costs that had taken place. Three years ago the costs per ton of ore amounted to 37s. 8d., and today, including developments, they had been reduced to 24s. 9d. per short ton of 2,000 pounds.

At the recent general meeting of the Kalgoorlie Electric Tramways, Ltd., hopeful views were expressed as to the future of the district. Mr. Allen H. P. Stoneham, who presided, referred to the question of the permanency of the towns of Kalgoorlie and Boulder. He said he personally still had a great belief in the permanency of Kalgoorlie. Some people had an idea that the mines will cease producing and that the town of Kalgoorlie will disappear in the bush from which it sprung, but he was perfectly sure that this will not be the case in our time. There is enough gold in the Kalgoorlie mines to keep them working for very many more years to come. The people of Kalgoorlie are continually erecting permanent buildings, laying out public gardens and parks, and making various extensions and improvements. The chairman always found the Australians a shrewd people, and he did not believe for a moment that they would put their money into permanent improvements unless they were convinced that the town was going to last. Mr. Octavius Beale, until recently president of the Association of Manufacturers of Australia, followed in the same sanguine vein. He said he had visited the mines at Kalgoorlie and had tried to form his own judgment as to their permanency. Many of them were being worked up to their boundaries, and no extensive work was going on outside. He asked Mr. Loring, of the firm of Bewick, Moreing and Co., "What do you think there is beyond the boundaries?" He replied that there was not the slightest doubt that they would find gold there, as they had done in the parts already being worked. It was everywhere believed that there was no possibility of the exhaustion of gold in Western Australia. Vast deposits had been found, and there was no doubt that other deposits would be found in the future.

Cabled advice has been received from the head office of the Mount Lyell Mining and Railway Company, in Melbourne, to the following effect: Ore treated during half year ended March 31: Mount Lyell mine, 144,780 tons; North Mount Lyell mine 57,740 tons; total 202,520 tons, averaging 2.41 per cent copper, 1.84 oz. silver, and 0.059 oz. gold; metal-bearing fluxes, 11,710 tons; purchased ore, 586 tons. Operations have resulted in a net profit of £255,648, inclusive of profits from superphosphate business (or £67,070 in excess of previous six months); this is after allowing for dividend and income taxes, £6,000, depreciation £8,713, and mining exploration not charged to mine preparatory works overburden account, £13,057. Credit balance to profit and loss account, £414,289. Liquid assets in excess of liabilities, £514,240, including stock on hand, but excluding outstanding debentures, £76,720. Cost of producing blister copper is 13s. 7.05d. per ton of ore. In terms of last half-yearly report, £25,000 has been placed to reserve fund, making £50,000, and the directors will place to reserve fund further £25,000, also £3,300 to insurance fund, making amount to credit of this fund £10,000. Dividend of 1s. 3d. per share, with a bonus of 1s. 3d. per share (amounting to £150,000), has been declared, payable June 15. Chemical works: Total output of superphosphates sold readily, owing to high-grade. Demand greater than the capacity of the works. In view of this and increased demand, entire plant being duplicated. Ore reserves: General manager reports, although no exact figures can be given, it would appear from all indications that tonnage extracted above 700-ft. level during the period has about been balanced by new accessions, and probable reserves below 700-ft. level are largely in excess of those assumed at commencement of half-year.

In an editorial on the Stock Exchange account now in course of adjustment the 'Financial News' remarks that "the variations in mining shares have been mainly in the downward direction. The past fortnight has not been propitious. A holiday break is never good for a bad market. The hardening tendency of money and the obscure outlook in Natal have told their tale. The Budget speech disclosed no indication that the Chancellor of the Exchequer understands that the restoration of public credit depends more on a steady stream of gold from the mines than on £500,000 set aside out of revenue for debt redemption. The wording of the proclamation inviting Chinese coolies on the Rand to become candidates for a free sea-trip at the Imperial expense gave a tardy hint that the Cabinet shrinks from dealing a too deadly blow at the source of the gold this country wants so badly, and at the one industry on which South African prosperity is based."

One of the few bright spots in an otherwise cheerless account has been Dolcoath, the shares of which rose from 18s. to 24½s. during the fortnight.

All those interested in Mexican mining (and the number is rapidly increasing) will learn with satisfaction that one of the miscreants who held up the Dolores bullion train in February last, has been captured, after a desperate struggle against five men, in the little Mormon settlement of Colonia Morelos, in Sonora. From an account which has been published it appears that Norcross and John Wright, one of his companions in the hold-up, were urging their fleet horses toward the border, after weeks of roaming through the mountains since the crime was committed. Supplies fell short. Norcross offered to go to the Mormon store to buy crackers and cheese. Rurales, the best mounted officers of the Mexican Republic, were on their trail. Suspecting the plans of the bandits, the rurales made a detour, and warned the Mormons. Norcross entered the store and faced the leveled barrel of a rifle held by a Mormon storekeeper. His own gun and horse were at a distance, and he could not reach his six-shooter. Seizing the barrel of the gun, he exerted his giant strength to the utmost. He is young and vigorously built. Struggling with the storekeeper, he made his way to the door, but the rurales, heavily armed, appeared. Norcross dashed for a corner of the store to draw a revolver and fire from shelter, but was shot from behind, the ball passing clean through him, breaking the thigh bone. Norcross was taken across country to Casas Grandes, then to Juarez, across the line from El Paso. There his wound, in horrible condition, was dressed by a surgeon for the first time. Norcross bore it stoically. A judge came to his cell and began his examination. Two days it continued. Norcross omitted no details, giving the names of his companions in the attack. The list included the notorious Billy Stiles, who has a long record as a bad man in the Southwest; the two Musgrove brothers, whose lawless deeds in Arizona form a lurid part in that Territory's crime record; John Wright and two others of less fame. All were Americans. After the search of the train had revealed the fact that the animal with the treasure had escaped, the bandits took flight, separating into several parties, thinking that not more than one detachment at most would be captured. The Musgroves and Stiles dared not make for the border, as they are wanted to answer for many crimes in the United States. Wright escaped after Norcross was captured, and is believed to be near Lordsburg, New Mexico. The others are still in the mountains, and the rurales are pushing the hunt. It has since transpired that Norcross died from his wounds.

The Dolores directors have marked their appreciation of William F. Smith's fidelity and pluck by presenting him with a Tiffany gold watch having a suitable inscription, also with a substantial sum in cash, accompanied by a copy of the resolutions of the board, recording the event.

To the many expressions of keen sympathy with the editor and staff of the 'Mining and Scientific Press,' evoked by the terrible calamity of earthquake and fire, your numerous subscribers and readers on this side now add their congratulations on the spirit and resource evinced by the announcement of the editor and business manager which has just reached London.

TORONTO, May 18.

The Cobalt mining boom has given a great impetus to speculation in mining shares and real estate. The multiplication of companies shows no sign of cessation, several new ones being launched every week, many of them with capitalizations running into the millions. A few of these represent actually producing mines, but the great majority are based on nothing more tangible than claims and indications. However, the public is not as yet in a critical mood; anything bearing the magical name of Cobalt and making a plausible showing on paper has an attraction for the small investor. With the object of giving some measure of protection to the public, a law has been enacted by the Ontario legislature requiring prospectuses of every company selling shares or debentures in the Province to be filed in the Provincial Secretary's department and copies must also be given to everyone buying shares or debentures. The advance of real estate prices in Cobalt and the neighboring towns is also of a highly speculative character, especially in view of the northward extension of the mining area, and the pushing forward of railway construction through the mineral-producing region, which may reduce the Cobalt area proper to merely the southerly fringe of the mineral belt. Nevertheless real estate is soaring in Cobalt. The Cobalt Standard Mining Exchange have just paid $15,000 cash for a lot of 70 ft. frontage, or at the rate of $215 per foot, and are putting up a modern $20,000 building, which is to be completed by the end of the present month. Applications have been made for office-room by brokers representing Toronto, New York, Detroit and other firms, so that the local stock market will be kept in close touch with the financial world.

The starting point for the numerous prospectors who are going up the Montreal river in search of gold, is the small village of Latchford, some eight miles south of Cobalt. A party of railroad men just returned to Latchford from an up-river trip into unsurveyed territory, report having struck it rich, having found a 12-in. quartz vein carrying gold and copper on or near Iron lake. They also found cobalt bloom and calcite veins. The party consisted of Alexander McDonald Sidney Dolmage and Wilbur Allen, all Grand Trunk Railway employees.

Meanwhile important new finds in the Cobalt area proper continue to be reported from day to day. At La Rose location another rich vein has been found, the outcrop showing masses of granular silver. A strike on the Foster property near Giroux lake, of considerable richness, was found to lead directly into the adjoining University location, already one of the leading shipping mines. When followed up, it was found that the cobalt bloom and nickel ore were replaced by native silver, the vein having a width of five inches. It has been traced 300 ft. and is supposed to extend considerably farther. The discovery is claimed to be the richest yet made in the district. The Nipissing Mining Co., who own 1,500 acres fronting on Peterson lake, the property being generally known as the Carl mines, are putting in a hydraulic plant. They will pump water from the lake and wash the surface soil so as to lay bare the bedrock. In addition to being a less expensive and more thorough method of prospecting than trenching, they will secure such free silver as may be mixed with the soil. The experiment of applying the hydraulic system to cobalt mining is watched with a great deal of interest.

The question of the permanency of the camp appears to be settled beyond dispute by the experience of the larger and more developed mines, the general result of which is that the veins are holding out well at the lower levels. Several mines are now below 100 ft. and find the veins frequently richer than near the surface. On the First Discovery vein of La Rose, the shaft is down 230 ft. and another shaft has been sunk to 185 ft.

and much driving has been done at the 90 ft. level. A second drift has been made at 200 ft., so that an approximate estimate can be formed of the amount of ore in sight, the conclusion being that there is a sufficient quantity available to keep the mine running for twenty years. At one of the Trethewey mines two shafts have been sunk, one being down to the 100 ft. level, at which much driving and some stoping have been done, the output so far being about $250,000. The other mine has not undergone as much development, but it has yielded nearly $500,000 worth of ore. Repeated reports have been started as to the sale by W. G. Trethewey of his interest in the mines, but they are emphatically contradicted.

Prospectors were busy in the early part of the season in Bucke township, which adjoins Coleman township to the north, and presents similar characteristics. Almost the whole area of Bucke is now staked out, but it is asserted that much of the alleged prospecting work was done when the snow was on the ground and it was impossible to make discoveries, and that many claims consequently will be disallowed by the mining inspector. The Gilpin Cobalt Silver Mining Co. who have the pioneer location in Bucke, are pushing development work. Trenching has disclosed seven veins on this property and smaltite has been found at a depth of 15 ft. Six men are at work. It is claimed that gold ore to the value of $7.50 per ton has been found on the property immediately adjoining, as well as smaltite.

The bill amending the Mining Act introduced by the Provincial Government in the Ontario legislature, a synopsis of the leading features of which I have previously given, has been passed. But the other measure for the taxation of mining lands was withdrawn owing to the shortness of time remaining for its consideration. It is understood that the question will come up next year. The scheme for giving bonuses to smelters, which was a portion of the bill, also stands over, the position of the Government being that any money devoted to this purpose should not come out of the general revenue, but should be raised by a tax or royalty on mining or mineral resources.

CHICAGO, May 19.

Whether the present conference between the operators and miners will come to any agreement is the most absorbing question now before the mining men. On the whole it does not seem likely that they will, despite the fact that relations are friendly and in the past the Operators Association and the United Mine Workers have worked in closer harmony in Illinois than anywhere else. It is confidently expected by leading operators as well as miners that work will be resumed sometime in June. The basis for this opinion seems to be mainly the fact that by that time the present stock of coal will be used up. The railways can be very brave up to the time when there is no coal with which to run their trains—"then," argue the miners, "they must come to terms." The miners are standing absolutely firm, confident in the strength of their organization rather than their cause. The large operators have so far held together with unexpected unanimity and much more than 90% of the tonnage is tied up. There are many mines running; over half the miners say, though this is probably exaggerated. These are however exclusively small mines supplying local trade. Since April 1 the coal traffic of Indiana and Illinois has practically ceased, yet the reserve supply was so large that there has been no especial shortage nor any large increase of price. It is evident that this condition of things cannot last. The cutting off of such a large portion of the production of the Middle West can not be compensated by increased shipments from the East, so that a change is shortly expected.

When the strike began the operators had no thought of attempting the destruction of the Union and the disruption of the interstate agreement. Several things have since occurred to materially alter the situation. On the one hand they have been surprised at their own ability to stand together and, on the other, the course of the miners has been unexpectedly exasperating. The withdrawal by the Union of pumpmen and engineers, except where the scale of 1903 was promised, in the face of a definite and clearly understood agreement to the contrary, is felt to be inexcusable. The almost contemptuous refusal to grant to the operators here arbitration on the exact lines asked for by the miners in the anthracite field has done much not only to anger the operators but to prejudice the case of the miners before the public. To the original demands of the operators, the continuance of the 1904-05 scale and the adjustment of the cost of shot-firers, have been added the open shop, abolition of the pit committee and various other items, including the strangely sounding demand, "That all men shall be allowed to work eight hours a day or forty-eight hours a week at the option of the operator!" This phase of the eight-hour question will appeal to Western men as new, and the phrase illustrates well the straights of the coal operators of the Middle West.

The most acute irritation has arisen from the shot-firers' law. This law, which was enacted by the last Illinois legislature, provides that all shooting in the mines be done by shot-firers who must be employed by the company. The purpose was to reduce the number of accidents. Whether, if roof-falls be taken into account, it has done so, is still uncertain. A priori it does not seem a good principle to require one man to fire shots placed and loaded by others and, while there are certain safeguards, it is far from certain that they are effective. The result to the operators has been to increase the cost of the coal an undetermined amount ranging from one cent per ton, as estimated by the miners, to 10c, as estimated by the operator. The latter estimate includes indirect, as well as direct, cost. It was held by the operators that the Union in lobbying this bill through, indirectly raised the cost of mining and relieved its members of labor and risk, after making a contract with the operators governing these points. In this, as in withdrawing the engineers, they have so seriously violated their contract, as also in numerous petty and unauthorized strikes, that the operators are asking that some penalty in the form of bond or tax on wages be provided for any future violation, if a new contract be made.

A more serious matter than the cost of shot-firing is the liability incurred by the operators. The shot-firers are members of the Union and the operators have no effective way of controlling either them or the men, yet the operators are financially responsible for deaths or accidents. Another matter of long-standing irritation is the systematic discouragement of machine-mining in Illinois. Candid officers of the Union do not deny this, but they explain the conditions as follows: After the rest of the State had been organized and the pick-men had been brought into the Union, the machine-men, particularly in the Danville district, refused to join. In order to shut off production here and force the men into line, it was necessary to make it unprofitable for the operators to use machines. At the time it was regarded as a temporary move, but being found to help the Union, it has been stubbornly held to. Payment for mining on a mine-run basis has been forced by the miners, and is another long-standing grievance of the operators.

When the miners, two years ago, accepted a reduction in wages, and when, a few days since, in the anthracite field they returned to work under old conditions rather than strike, they exhibited most unusual reasonableness and Mr. Mitchell showed his greatest generalship. It is therefore surprising that in Illinois they refuse to rectify injustices which they can hardly help recognizing and which in fact many of them do privately recognize. The difficulty is probably less with the leaders than the followers. It is a prime essential for a labor leader to win or seem to win benefits for his followers, and in Illinois the officers of the United Mine Workers have been so successful in this particular that they have set themselves a standard difficult to live up to. They began in 1897 when by open and unrepressed violence at Virden they won against the un-united operators. This battle has become a sort of Lexington in their minds and is referred to as a sad necessity due to the stubbornness of certain individual operators. Since then, despite the organization and power of the Operators Association, conditions have improved and wages have mounted steadily. The strike fund has grown to nearly a million dollars and the miners have come to believe they cannot be defeated. The operators have collected some $6,000,000 in dues for the Union and have worked with them cordially in building up the system of collective bargaining and interstate agreements. Probably everyone who is familiar with the coal industry of the Middle West approves of this system of interstate agreements and regrets its passing, but it is difficult to see how it can be saved. The miners certainly will not go to work except on the 1903 schedule. Whether they will grant other concessions sufficient to compensate the operators for yielding this, remains to be seen. The Union officials cannot retain control of the organization if they back down on this show point after having won in Iowa, and with so many individual operators. The difference in cost on this point alone is not sufficient to warrant the operators attempting to bring in non-union men. The only shipping non-union mine in Illinois is now, after three years, still guarded by a stockade surmounted by search-lights and with Gatling guns. The immediate outlook, therefore, for more non-union mines is not encouraging. If, however, concessions can be made in the matter of shot-firers, machine-differentials, etc., it is possible an agreement based on the 1903 schedule can be worked out. If the operators can force arbitration by a national commission, they will almost certainly win more than this. If, however, the Union officials do not find themselves strong enough with their organization to make such a settlement, the operators are likely to be forced to settle on other terms. A few will fight, but the big fight under such conditions will come a few years later, when consolidation shall have gone a few steps further and the railways are in more direct control.

SALT LAKE, May 14.

E. A. Wall, of Salt Lake, owner of the Starless group of Bingham, announces that he will equip that property with compressor and other machinery. The Wall mill, where the ore will be treated, is to be overhauled and enlarged.

The Silver King Mining Co. has filed answer in the trespass and damage suit, instituted some aime ago by the Magnolia-St. Louis Mining Co., entering a general denial to allegations set forth in the complaint. While admitting the extraction of ore from the disputed ground—the St. Louis and Magnolia claims at Park City—defendants justify their action on the ground of apex rights. The suit was brought to recover $900,000, alleged to be three times the value of ore extracted from one level, of which plaintiffs had knowledge. Following the filing of the answer, the plaintiff filed a suit in equity in the Federal court demanding that the Silver King Co., and David Keith and Thomas Kearns, president and manager, respectively, show cause why an injunction should not issue restraining them from mining or extracting ore from the property in question. The court is also asked to make an order permitting the engineers of the Magnolia-St. Louis Co. to enter workings of the defendant company for the purpose of inspection.

The Sacramento Gold Mining Co. has been sued by the Herschel Gold Mining Co. for trespass and damages in the sum of $231,000. The plaintiffs allege ore has been unlawfully extracted from the Remnant and Pegasi claims, at Mercur, in Camp Floyd district. The Yampa Smelting Co. at Bingham has six MacDougall roasters and two Edwards furnaces in operation. Five more MacDougalls have been ordered. The directors of the Silver King Mining Co. have reduced the monthly dividend to $50,000, the management giving pending litigation, and the probability of the purchase of additional ground as the reason for the cut. The Silver King Co. has paid $10,200,000 in dividends.

The ore shipments from Park City last week aggregated 2,366 tons, the shippers and amounts being: Daly-Judge, 482 tons ore, zinc middling, 250; Kearns-Keith, 135; Daly-West, 600; Silver King, 612; American Flag, 264; New York Bonanza, 23. The production of Tintic district last week aggregated 183 carloads, the shippers and amounts being: Gemini, 23; Centennial Eureka, 50; Eureka-Hill, 6; Beck Tunnel, 6; May Day, 7; Yankee Con., 5; Uncle Sam, 6; Brooklyn, 2; Bullion Beck, 10; Dragon Iron, 16; Swansea, 1; Scranton, 2; Ridge & Valley, 4; Black Jack, 5; Lower Mammoth, 3; Grand Central, 8; Carisa, 4; Mammoth, 20; Ajax, 2; Victoria, 2; Victor, 1; Undine, 1.

At the Carisa mine, in Tintic district, connections have been made with the Sioux-Ajax tunnel through which ore will hereafter be sent out at reduced cost.—New equipment has been ordered for the Star Consolidated mine at Tintic, including a hoisting plant. Recent development in this mine is encouraging.—The Mammoth Mining Co. of Tintic district has disbursed another dividend, making a total of $2,020,000.—The Honerine drain tunnel, at Stockton, is in 10,200 ft. The mill is still idle.—The zinc concentrator at the Hornsilver mine, in Beaver county, is in operation and several car loads of zinc concentrate have been shipped to Iola, Kansas. The plant is reported to operate successfully.

The Overland mine at Sunshine, E. W. Clark of Ophir, Utah, manager, will soon be in shape for regular production. For a year the company has been sinking a new shaft, necessitated by the caving of the old incline. It is expected the mill will be running before July 1. The ore now being developed, is said to run over $4 gold per ton.—At the annual meeting of shareholders of the Annie Laurie Mining Co., operating in the Gold Mountain district, George A. Baird, of Sharon, Pa., was elected president; A. A. Ball, Kimberly, Utah,

secretary, and S. M. Levy, of the same place, manager.—The first month's run of the Sevier Consolidated Co.'s mill in Gold Mountain district, is said to have given satisfactory returns. The gold saving on the plates was 94 per cent, and of the gold and silver contents combined, 90 per cent.—The Ohio Copper Co. has decided to sink a new shaft on the All Well's vein at Bingham, and will install machinery to carry development work to greater depth than heretofore.

June 5 has been set for the hearing of argument in the pending smelter-smoke cases.—An important strike is reported at the Utah Consolidated mine at Bingham, said to be in virgin ground and that the orebody, which is 25 ft. wide, carries seven per cent copper.—The management of the Swansea mine, Tintic district, will re-open the 800 level. The company is shipping 700 tons monthly.—The management of the Boston Consolidated Mining Co. has placed an order for 312 Nissen stamps for the new Garfield concentrator, construction of which has begun. Preliminary tests at the company's experimental mill in Bingham showed that one stamp will handle ten tons of the company's porphyry ore per 24 hours.

BUTTE, May 19.

John D. Ryan, president of the Anaconda Copper Mining Co., at the recent annual meeting in Butte, submitted the following report for the year ending December 31, 1905:

Receipts.

Sales of copper, silver and gold	$17,429,098
Royalties	65,441
Dividends on investments	32,100
Rental of water rights	50,000
Miscellaneous receipts	96,285
Net profits of subsidiary departments after deducting depreciation	300,174
Copper, silver and gold on hand—copper at cost, silver and gold at selling price	5,761,105
Total receipts	$23,734,203

Disbursements.

Copper, silver and gold on hand at the beginning of the year	$ 6,336,427
Mining expenses, including development and depreciation	5,403,585
Ore, matte and copper purchases, including transportation and purchasing expenses.	349,258
Transportation of ore from mines to reduction works	226,515
Reduction expenses at Anaconda, including depreciation	4,046,822
Transportation of metals from West to East, refining and selling expenses	1,729,175
Administration expenses	54,699
Total	$18,146,481
Balance	$ 5,587,722
Add. interest	131,106
Balance profit to balance sheet	$ 5,718,828

The balance sheet as of December 31 shows:

Assets.

Mines, mining claims, land, etc	$20,430,757
Buildings and machinery, saw mills, etc	4,267,516
Investment in sundry companies	531,560
Total fixed assets	$25,229,833
Insurance unexpired	56,079
Materials and supplies for future use	1,508,761
Deferred assets	1,564,840
Merchandise held for sale	628,491
Copper, silver and gold	5,761,105
Loans and accounts receivable and cash	6,749,605
Current assets	13,139,201
Total assets	$39,933,874

Liabilities.

Capital stock, 1,200,000 shares of $25 each	$30,000,000
Accounts, wages and pay and taxes accrued	1,626,286
Dividend warrants, not presented	17,016
Div. No. 21, payable Jan. 18, 1906	1,050,000
Current liabilities	2,693,302
Balance surplus, Dec. 31, 1904	4,971,744
Profit for year ended Dec. 31, 1905	5,718,828
Total surplus	$ 10,690,572
Deduct dividends No. 10, 20 and 21	3,450,000
Surplus	7,240,572
Total liabilities	$39,933,874

The mines, reduction works and subsidiary departments were in continuous operation during the year, and no unusual accident or extraordinary interruption occurred to interfere with the work. The mines were developed during the year to greater depths than have been reached heretofore in the Butte district, and with the increased depths the life of the mines and grade of the ore are assured for many years to come.

The Anaconda mine is now opened on the 2,400 ft. level, and the Never Sweat and St. Lawrence on the 2,200, and at these depths the veins show fully as good in size and in value of ores as in any of the levels below the 1,000 ft. level.

The mining properties owned by the company, outside of the working mines, have been developed to a considerable extent during the year, with satisfactory results and it is the policy of the management to continue especially during prosperous times, active work in developing the large holdings of the company that are not now productive.

The arrangement under which the company leased the new reduction works of the Washoe Copper Co. and abandoned and dismantled its own reduction works at Anaconda has been in effect long enough now to demonstrate fully the wisdom of the trustees in entering into it.

During the year 1901, which was the last full year during which the company operated the old reduction works, 1,390,460 tons of ore were treated, and the capacity of the plant as it stood was reached; to modernize and increase its capacity was decided by competent engineers to be impracticable.

The new works of the Washoe company were leased for a long term of years on a reasonable rental basis which rental covers only interest on the amount the plant cost, with usual allowance for depreciation.

During the year 1905, 1,626,306 tons of ore from its own mines, and slags, slimes and flue-dust taken from the old works, were treated at the new reduction works at a difference, after paying rental, of $1.5886 per ton in increased savings of metal values and decreased cost, as compared with the old works in the last year of their operation. This saving amounts to $2,583,549 on the ore treated for your company during 1905.

In addition to the advantage of increased savings and decreased cost realized under the new arrangement there has been recovered in salvage and from metal values in the dumps of the old works since they were abandoned, $3,645,625 net profit to March 1, 1906, and the cupreous material yet in sight at the old works is estimated at about $1,750,000, or, with net profits already realized, about 85% of the book value of the old works when they were in operation. Included in the book value of the old works is the refinery plant, which still stands intact, ready for operation, but the company does not continue its operation as contracts have been made with refineries at the seaboard that make it more profitable to ship the product and have it refined at the seaboard than to refine it at Anaconda.

Summing up, your trustees find they have realized for your company from the arrangement made with the Washoe company for the lease of the new reduction works, an additional profit amounting to a very large sum each year on the output of the mines, and have recovered practically the entire value of the old works in selling off the machinery and working over the slag dumps and slime ponds that could not be worked profitably in the old works.

The mines in operation during the year were the Anaconda, Never Sweat, St. Lawrence, Mountain Consolidated, Bell, Diamond and High Ore. The Galatin and J. I. C. were opened and operated and a limited tonnage taken from them in the latter half of the year

The mines of the company produced 1,543,316 wet tons of ore, of which 61,149 dry tons of smelting ore remained on hand at the reduction works at the close of the year, leaving 1,470,694 dry tons treated at the works.

The plants and equipment of all of the mines of the company are capable of doing the work satisfactorily and economically for a long future. The use of electrical power has largely increased and will continue to increase at the mines, effecting a very considerable saving over power generated with coal. At the present time most of the air-compressing machinery is electrically driven, and it is contemplated to do most of the pumping from the mines with electric power.

The mines of the company are now drained almost entirely through the pumping plant in the high ore shaft, and the precipitating plant, through which the water from the mine is taken, extracted during the year copper sufficient to pay all pumping expenses.

During the year the Anaconda shaft has been sunk 400 ft. and cross-cuts completed to the veins on the 2,200 and 2,400 ft. level; the Never Sweat shaft has been sunk to the 2,400 ft. level and cross-cuts completed and the vein opened on the 2,200-ft. level; the St. Lawrence shaft has been sunk to the 2,000-ft. level (equivalent to the 2,200 Anaconda) and cross-cuts driven to the vein on that level; the High Ore shaft, now at the 2,200-ft. level, is being sunk and will be continued to a depth equal to that of any of the company's mines; the Diamond and Mountain Consolidated shafts are both opened to the 2,200 ft. level, and have not been added to in depth during the year.

The reduction works treated for all companies during the year 2,650,868 tons of ore and other cupreous material. Of this, 1,470,694 tons of ore from the mines, 44,566 tons of slime and 23,900 tons of flue-dust, 82,789 tons of slag and 4,357 tons of miscellaneous cleanings from the old works were treated for your company from which was produced 95,443,730 lb. fine copper, 3,116,880.945 oz. silver and 19,165.429 oz. gold, in the form of anodes, which were shipped to Eastern refiners.

During the year the Washoe Copper Co. added to the blast-furnace capacity of the works by making connections between furnaces and reconstructing the plant so that three large furnaces and one small one are now in operation, with a daily capacity of 4,700 tons of all material, as against seven small furnaces with a daily capacity of 2,700 tons at the beginning of the year Eight new McDougall roasting furnaces were added in the calcining plant, and it is intended by the Washoe company to still add more roasters, as the present product of the concentrator is greater than can be satisfactorily handled with the present capacity. The small reverberatory plant now consists of two furnaces 102 ft., four 112 ft., and one 115 ft. long, with boilers in flues of all the furnaces, furnishing steam about sufficient to operate the smelter power-house.

The concentrator is being equipped with electric power which will show a material decrease in the cost of operating when installed.

These extensions and improvements are being made by the Washoe Copper Co., and your company will pay increased rental based on the increased cost of the plant.

BUTTE, May 20.

The machinery for the new hoisting plant of the East Butte Co. has been received and is being put in place. The equipment consists of engine, air compressor, three boilers, furnace frame and smokestacks. The company is cutting a station at the 400 ft. level and a pump will be installed there. With the new plant, sinking will be more rapid and economical. The various lessees are shipping ore, and the bins are full.

La France Copper Co. has begun pumping water from the Lexington mine, which for years has been flooded up to the 550 ft. mark. The mine is 1,465 ft. deep and there are several miles of workings below the water level. The pumping capacity of the machinery is about 1,000 gal. per min. at which rate it is expected the water can be pumped out in about four months. The pumping will not interfere with the mining that has been going on in the upper levels, from which 100 tons of copper and zinc ore has been shipped daily for some time. United Copper is the principal owner of La France.

The Columbus-Butte Mining Co., organized to succeed the Jenny Dell Mining Co., has itself become involved in debt and has been practically forced to the wall. The company has been developing the October and Jenny Dell mines but had little money to go on, and was unable to take up the bonds on the properties. The stockholders, fearing to lose all their investments, are trying to raise money. The Jenny Dell is in the northwestern portion of the district.

The Butte-Milwaukee Mining Co. is making preparations to put up a hoisting plant on the Colonel Sellers and sink the shaft to 1,200 ft., the purpose being to develop that mine and the Bird from that shaft. Another shaft will be sunk on the Florence. The Pollock is developed and is worked by lessees. In addition to the mines named the company also owns the Stonewall, in Butte district, and seven copper claims in Argenta district.

The company, to tunnel under the mountain range east of Butte, has decided on the site for the adit which will be driven 4,500 ft., far enough, it is thought, to cut the veins traversing the property. It will give a depth of 2,500 ft. The Corrys, who formerly owned the ground now embraced within the Pittsburgh & Montana Co.'s holdings, are at the head of the enterprise, and a number of mining claims owned by them will be put into the company. Sinking has been resumed by the Eagle Mining Co. on its property north of Butte, and the shaft will now be sunk to 500 ft. Pumping machinery has been installed.

The Lewisohn General Development Co., which for several months has been pumping water from the Altoona mine, has cleaned out the old workings and J. Parke Channing is making an examination of the properties, which will determine whether the Lewisohns will take up the options on the Altoona group or not.

MINING SUMMARY

ALASKA.

In Tanana district, gravel dumps gotten out during the past winter are numerous and large. It is estimated the gold output will be 50 larger than that of last year.—— The Arctic Mining Co. is reported to have made a big strike in the Port Clarence district, where they have 12 ft. of gravel, seven ft. of which is pay-dirt. This is on Sunset creek, where it owns all of the creek and bench claims. Pans running as high as 25 c. have been found on the benches.—— The exact distance from Dawson to Fairbanks by the winter trail, by way of Eagle and Circle, is 410.7 miles.—— Press dispatches of May 22 state that Fairbanks, the metropolis of the Tanana region, was destroyed by fire on tha date.

ARIZONA.

COCHISE COUNTY.

The Cole shaft of the Lake Superior & Pittsburg, near Bisbee, is to be sunk to 1,500 ft. In addition to this a third shaft will be sunk at this mine, southeast of the present mine and near the Calumet & Pittsburg line. Work will begin this year. This mine is now producing copper at the rate of 10,000,000 lb. per year, which will be increased later in the summer with the blowing in of No. 4 furnace.—The Copper Queen is to put a large electric pump in the Czar shaft, to handle all water from the upper end of the mine. The Copper Queen is employing 4,000 men at the mines and smelters, and is turning out 8,500,000 lb. of copper monthly.

The mines at Bisbee, known as the Bonanza Circle, are to be incorporated under Minnesota laws, absorbing the Calumet and Pittsburg, Lake Superior and Pittsburg, Pittsburg and Duluth and the Junction companies under the same management. These properties adjoin the Calumet and Arizona mines. The merger is planned to secure greater economy in the mining and smelting operations. The properties are so situated that they are inter-dependent and the shafts of each are so situated that they are necessary to the economical operation of their neighbors. The new concern will be one of the largest copper mining companies in the country. Production is now confined to shipment of ores to the Calumet and Arizona smelter at Douglas, and it is proposed to erect separate smelters, largely increasing the output.

(Special Correspondence.)—A gold discovery has been made in the Saddle Mountain district by Newton Robertson, I. N. Robertson and O. N. Bantu, of Safford. Two samples of ore from the Summit claim, taken near the top of the range, assayed respectively $48 and $59 per ton gold. The shaft on the Summit claim has been sunk 12 ft. and the vein has widened from four to eight inches. The last assay ran about $80 gold.

Tombstone, May 20.

MOHAVE COUNTY.

(Special Correspondence.)—F. H. Crafts, of Chloride, 22 miles north of Kingman, is closing up some mining deals. These sales will inaugurate new mining activities. C. H. Burlock, of the San Diego Mining Co., is at Union Pass superintending development of the company's property. Richardson brothers have completed driving 125 ft. on the 300-ft. level of the O. K. mine at Union Pass.—T. Ewing, being short of water at the Vivian mill, in San Francisco district, has purchased the Cottonwood canyon water and pipe line and is now laying a two and one-half inch line from there to the mill.—At the Victor and Virgin group in the River range, two shafts are being sunk with three shifts. When the mine is ready to produce ore in sufficient quantity, Mr. Ewing will erect another mill for this group, laying a branch water pipe from the one now being laid.—At the German-American mine, in San Francisco district, the new compressor plant is running smoothly and the machine drills are in constant operation. The mill is running day and night on ore taken out in development.—W. J. Agler, superintendent for the Treasure Hill Mining Co., has commenced development on the company's mines at Stockton Hill, with Morgan Jones as foreman. The first work done under the new management resulted in a rich strike of high-grade ore, which was opened up in one of the lower tunnels on the Dictionary ground. A winze was started from the bottom of this old tunnel to connect with the next lower tunnel, and in this winze the rich ore was found. It is one of the most important strikes made in that district in many years.

Kingman, May 20.

PINAL COUNTY.

(Special Correspondence.)—The Calumet Co., of Douglas, has a representative on J. K. McCarthy's group at Riverside, figuring on the purchase of that property. Sinking on Shaft No. 2 is about to be commenced.

Douglas, May 20.

YUMA COUNTY.

E. T. Larson of Ironwood, Mich., has taken up his option to purchase the lease of the Golden Eagle & Bonanza Gold Mining Co., situated at Harqua-Hale and has organized the Harqua-Hale Mining Co. to own and operate the lease. Articles of incorporation have been filed. The property has a bullion record of $5,000,000, but has been shut down for several years. The new Santa Fe road to Salome passes near the property which is equipped with a 40-stamp mill, hoisting plant and a pipe line five miles in length, which furnishes a water supply. The deal includes title to the tailing from all the ore previously mined, estimated in excess of 100,000 tons, which it is thought can be treated profitably by cyaniding. In addition to this, there are 50,000 tons of ore available on the surface.

CALIFORNIA.

AMADOR COUNTY.

The Mitchell mine has been cleaning up the ore left on the dump by the lessees. The average of the rock was low, and whether it will leave a balance over the milling expenses, to go toward the liquidation of the claims of the lien holders is doubtful.—At the Oneida mine a 12-ft. vein has been exposed on the 2,400-ft. level. It is low grade. The vein will be explored for the pay-shaft.—The Wildman mine at Sutter creek is again in operation. Underground work was started this week.

KERN COUNTY.

It is reported that ore containing both gold and platinum has been discovered at Linns valley. Thus far only qualitative tests have been made.

MONO COUNTY.

A strike is reported four miles from Masonic. The district is described as consisting of large dikes of mineralized porphyry containing gold. Thus far only low-grade ore has been found, but the ore exists in large quantities, and pans free gold. A townsite has been laid out, and a number of people have gone there. The camp is near the Nevada line.

NEVADA COUNTY.

The New York-Grass Valley Mining Co. has decided to put in a 100-ton cyanide plant at their mine at Grass Valley. The capacity of the mill is to be increased by the addition of stamps. Coarser crushing is to be tried, and it is thought that by this increased capacity, and operation of the cyanide plant, a higher percentage of gold will be saved at less expense.

PLACER COUNTY.

J. W. Price has located what he believes to be the extension of the Dairy Farm copper mine. The discovery was made in the bed of Bear river. He has sunk several prospect shafts on it, the deepest being 30 ft. At that depth the vein is six feet wide. Some of the ore contains a good percentage of copper and some is free-milling gold ore. Forty men are employed at the Dairy Farm mine. At a depth of 400 ft. the vein in that mine is 70 ft. wide.

SAN BERNARDINO COUNTY.

It is reported that the vein of a new discovery has been traced for 4000 ft. with a surface width of six feet, near Kelso. Samples assay from $7 to $120 per ton. Kelso is a station on the Salt Lake railroad, about 15 miles from the Nevada State line, in New York district, a few miles west of Manvel.

TRINITY COUNTY.

The John Poeth claim on Big Boulder creek, a branch of Coffee creek, is being developed by a shaft which is down 150 ft. and drifts, one each way, at the 140-ft. level. The vein maintains a width of about two feet throughout the shaft and the drifts. A ditch and pipe-line are being put in, preparatory to installing a compressor. A cyanide plant will be added later in the summer. At present there are ten men working under the direction of J. B. Batz.

The Golden Jubilee, just south of the Poeth mine, is actively preparing to resume stoping and milling. A crew of men is overhauling the mill and cyanide plant and repairing the ditch and replacing the pipe-line. When in running order the mill and cyanide plant will handle 20 tons per day. The milling will be delayed because of a loss of time due to the forwarding of supplies from the East which would have ordinarily come from San Francisco. In the lower tunnel, the orebody has been encountered and development shows an enormous amount of ore between this and the upper level. The work is under the direction of W. L. Chapman.

The Blue Jay, the scene of the Graves brothers' strike in 1897, is being developed by a cross-cut tunnel. They have recently cut the vein, which is 35 ft. wide and assays have given from $8 to $117 per ton. Further development in the shaft is delayed pending the arrival of a hoist and pump. This property is in Morrison gulch, above the Morrison gulch hydraulic mine.

The Bonanza King is building a saw-mill and road preparatory to installing a 10-stamp mill. At present 45 men are employed; this force is to be increased later.

The Caribou mine, on the Salmon river side, will soon have a force of men driving the cross-cut tunnel to intersect the large vein which outcrops on the surface and driving on the small veins that have already been cut. The tunnel will have to be driven about 1,000 ft further.

COLORADO.

GILPIN COUNTY.

At the Gulch mine in Lake gulch, a depth of 450 ft. has been reached in the shaft, sunk on a vein of low-grade milling ore with a streak of fair-grade smelting ore. The property is owned by William Mitchell and sons. Several cords of mill ore are in the bins and a shipment of smelting ore is being taken out.—At the Chemung-Belmont mine near Lake gulch, a depth of 790 ft. has been reached.—A new 50 h. p. boiler has been put in the Pozo mine, in Nevada gulch.—A new shaft building has been erected at the Argo mine, in Russell district, by the Faraday Mining Co., in which Chicago people are interested, and machinery, consisting of a 10 by 12 single engine and a 35-h.p. boiler, has been installed. The shaft is down 160 ft. and is to be sunk 200 ft. deeper.

SUMMIT COUNTY.

(Special Correspondence.)—Numerous new strikes have recently been reported in Breckenridge district. In the Jessie mine a four-foot vein of rich ore has been discovered between the second and third levels and the management is opening this up. Three feet of this vein is streaked with lead sulphide, rich in gold and silver. The other foot is high-grade milling gold ore which assays from 200 to 300 oz. silver per ton and 20 to 25 oz. gold, making a total value of $550 to $700 per ton. The company's mill is being put in good shape and will be started up next month.—The old Union Mining and Milling Co. is running its mill to its full capacity on full time. The main tunnel workings are producing good concentrating ore. The Wellington mine is making regular shipments of zinc and lead ores, and is shipping its milling ore to the Old Union mill.—The Oro mine in French gulch, which in five years produced over $1,000,000 in gold, silver and lead, but which has been in litigation for 13 years, is again in shape to resume work, the litigants having arrived at an amicable settlement of their differences. This mine may now be expected to make big shipments, adding materially to the production of Breckenridge district.—The Beaver Creek Gold Mining Co., which has been operating the Lucky mine the past 18 months, has purchased the Minnie mine and mill which adjoins them on the southwest on Mineral hill. The Minnie is being operated under lease and will so continue until the end of July when the new company will take possession.—The Country Boy mine is worked by the Lanyon Zinc Co. under lease. The management is drifting on the vein and preparing to stope ore which runs 40 to 55% zinc. The pay-streak is from 24 to 38 in. wide. The ore is shipped to Iola, Kansas.—The Mary Verna Mining Co., operating the Ten Mile canyon in Frisco district, has struck lead ore in their main tunnel which runs into Royal mountain from the Ten Mile river side and taps the vein at a depth of 1,200 ft. This is an important strike as it is the deepest work in this mountain.—Albert Newton has sold his property, adjoining the Victoria mine on Mount Royal, at Frisco, to a company, which will push development with vigor.—The Summit Banner Placer Mining Co., operating under the management of Lemuel Kingsbury in Iowa gulch, is about to start the season's operations. The pipe line and boom are now in order and washing has commenced and the entire plant will be in full operation by the 20th of the month.

Breckenridge, May 20.

TELLER COUNTY.

The Mine Owners' Association at Cripple Creek has decided to begin the prosecution of persons accused of stealing high-grade ore in the district, and criminal action against several alleged violators will be begun. It was reported to the association that there was $9,000 in the special fund, derived from high-grade ore which had been confiscated, to be used in the prosecution. One of the members of the association said that the action taken was the beginning of a

movement which would make high-grading unknown hereafter in the district. S. Jensen, an assayer, is one of the men to be prosecuted by the association. It is alleged that a number of the high-graders, through Jensen as agent, shipped a car of ore to a reduction plant in Pueblo. This ore was confiscated by the Mine Owners' Association on the ground that it was stolen. Jensen brought suit against the railroad company, securing judgment for $300, and as a result, the Mine Owners' Association will take the case to the Supreme Court. Jensen then sued the Eagle sampler, which handled the ore for the association, but he lost his case, Judge Cunningham deciding against him a few days ago. The ore was valued at $2,700.

IDAHO.

BLAINE COUNTY.

L. A. Gowdy, a sheepherder, while attending sheep on the Wolftone slope of the Red Cloud mines last fall, discovered the outcrop of a vein of galena, and with a piece of hoop-iron he turned up 50 lb. of ore. He filed notice of the location in Hailey, naming his claim the Olive. Being too late in the season to do anything, he awaited the return of spring, when he sold a half-interest to A. Holmes, who went to the claim a few days ago and took samples, one of which assayed $232.20 silver, and 71½% lead; the other 99 oz. silver and 32½% lead.

LEMHI COUNTY.

The Queen & Crescent Mining Co., operating the Queen of the Hills mine near Salmon, have cut fine ore in their crosscut at 1038 ft., and the miners have driven ten feet into the vein without reaching the further wall. The face is 405 ft. from the surface.—The Junction Mines Co. has ordered the shaft sunk another 100 ft.—The placer season is opening. There is sufficient snow in the mountains to make a prosperous season for the placer miner if the snow does not go off with a rush.—Details of the transfer of the Yellow Jacket mine have been completed, and this property, after an idleness of ten years, will be started up July 1. The mine is equipped with a 60-stamp mill run by water-power.

MICHIGAN.

KEWEENAW COUNTY.

A mill with eight gravity stamps is being erected on the Tamarack Co.'s Cliff mine for the purpose of treating part of the waste pile at the abandoned property. Henry Warren is in charge of this work, and will operate it on a leasing arrangement, independent of the Tamarack Co. Jigging and other methods of concentration are to be applied to the recovery of copper. The Cliff dump accumulated when attention was given largely to mass copper and stamp copper was a secondary consideration. A grade of rock was rejected at that time which might profitably be sent to mill under modern conditions. It is the calculation of Mr. Warren that the Cliff dump contains enough rock of this character to justify an effort to recover the copper in it. It has been exposed for many years to the weather and therefore will crush much easier than fresh rock.

NEVADA.

DOUGLAS COUNTY.

The new camp called Buckskin is 15 miles from Wabuska. Prospectors and others are going into the new district and some good prospects are reported. The goldbearing veins are found in what is described as rhyolite, and in a general way the geology is said to resemble Goldfield, though, as yet, no sensational strikes have been made. The principal prospect is the Kennedy mine which has already been incorporated. A shaft is being sunk on this property and is down 25 ft., on a four-foot vein which is said to assay $80 in gold. Wood, suitable for fuel, and water are obtainable in the district, which is six miles long and two and a half wide. On the Iron Mountain a shaft is down 40 ft. and prospects well. The townsite has been incorporated, and most of the lots sold. At present the town consists of tents and tent-houses.

LINCOLN COUNTY.

G. Walmouth and F. Ennis, owners of the Diamond group, on Virginia river, brought into Caliente samples of ore from the bottom of a 50-ft. shaft sunk on their Ruby claim. They sunk on a four-inch vein of ore going $80 per ton. This vein widened, and at 50 ft. was the full width of the shaft, but dropped in value to $20 per ton gold. Six feet deeper the vein pinched to two feet, but showed gold going $450 per ton. They are sinking, and when they reach the 100-ft. mark will crosscut and drift.—— A strike of gold-silver ore is reported from the Green Mountain Boy, west of Caliente and south of De Lamar. The owners, Foote, Richards & Blake, have drifted 140 ft. on a 26-inch vein of $45 ore and have struck a blind lead showing $132 gold and silver in a three-foot vein. They are sacking ore for a test shipment.

LINCOLN COUNTY.

(Special Correspondence.)—The Quo Vadis group 23 miles southeast of Las Vegas, has been bonded, and deed placed in escrow, in First State Bank at Las Vegas. Consideration $100,000. The bond is from A. D. Catlin and co-owners, to John E. Phillips of Denver, for himself and co-owners, among whom are J. A. McKinney and A. D. Shoup, of Colorado Springs, who have been here with Mr. Phillips examining the property. Mr. Shoup represents Verner Z. Reed. Harry Adsit has also been here in this connection.

The Lucky Strike group, 27 miles northwest of Las Vegas, has a car loading at its side track for initial shipment.

The Potosi group, 25 miles southwest, is shipping 50 tons daily. The threatened litigation on this group has been compromised.

The Nevada Home Oil Co., with property 45 miles northwest, expects to commence boring soon. The surface indications are stated to be favorable.

Las Vegas, May 21.

NYE COUNTY.

(Special Correspondence.)—At the Consolidated Manhattan, of East Manhattan, the tunnel is now in 44 ft. At 38 ft. a vein was encountered, five feet wide, which gave assays of $30 per ton gold. This vein is only one of a series which traverses the company's property. A contract was closed the early part of the week to drive the tunnel 200 feet.—The Manhattan Mammoth adjoins the Consolidated Manhattan on the east, and is an extension of the vein which crosses the Consolidated holdings. The company are developing their property by tunnel, and will soon have a compressor installed. They have the same character of ore as their neighbor. A contract for 200 ft. of work has also been let.—The Manhattan Buffalo is west of the Consolidated Manhattan at East Manhattan. Development consists of two shafts. Both are in ore.—The Manhattan Consolidated, the first mine of the camp, is still holding its reputation. The force has been increased. Shipping ore is being piled on the dumps.—The Manhattan Mother Lode joins the Manhattan Consolidated on the southeast. A tunnel is being driven from the base of the hill, in which good ore has been cut.—Another vein was found recently on the Iron Queen claim of the Cowboy Co. This vein consists of black quartz similar to that found on the Georgey group at Central, and asays well from the surface. The company shaft on the Iron King claim of the Cowboy Co. is improving as depth is gained. The heavy iron sulphides which were first encountered at a depth of 60 ft. are still being found. A combination of men have leased the surface of the Iron King for placering. They will install dry washers. One machine is on the ground, and others will follow.—The shaft on the Bullhead claim, west of the Cowboy, is high grade ore, and shipments will soon be made. They are working in sulphide ore.—The hoist on the property of the Manhattan Dexter is working to its fullest capacity, and ore is being sacked. The shaft is down over 200 ft.—At the Manhattan-Nevada Gold Mines, the company shaft and drift are progressing, and they expect to soon reach the black quartz ledge cropping prominently on the surface of the Georgey group. Four veins have been cut in this drift, which is in 28 ft.—Surface prospecting has been carried on the last few days on the Copper Farm, El Dorado No. 1 and El Dorado No. 2 claims of the Manhattan Nevada Gold Mines, and several veins have been found.

Manhattan, May 20.

WHITE PINE COUNTY.

At Ely several of the large mining companies are getting well-drilling and diamond-drilling outfits, to test their ground in advance of the usual mine development. Recently the Giroux Co. received a diamond-drill having a capacity of 1,200 ft., and the Ely Central Co. have two of the same kind coming.

NEW MEXICO.

SIERRA COUNTY.

The Sierra Consolidated Gold Mining Co. has installed a large hoisting engine on the Opportunity mine where they will sink a three-compartment shaft. At the shaft on the Snake claim, which is now down 300 ft., sinking is being continued. The company has the Hager saw-mill under lease, and is turning out lumber for use at the mines and in the construction of the 50-stamp mill which it will put up on the Snake mine.

The Empire Gold Mining and Milling Co. is running steadily with a large force on the Bonanza mine. It now has the mine connected with its 20-stamp mill by a narrow gauge railroad; the mill is running steadily on ore from the Bonanza mine.—The Black Peak Gold Mining Co. is working the Wicks mine under lease. R. H. Hopper is working men on copper properties in the Caballo mountains, an undeveloped mining district, where large bodies of copper ore are being developed.

OKLAHOMA.

LOGAN COUNTY.

The Rosedale Mining Co., a Kansas City concern, has completed a cyanide plant at Mount Scott, in the Wichita mountains. Its capacity is 25 tons daily. The company's ore is said to assay $4 gold per ton. A carload of machinery was received during the week by the Kentucky Mining Co., also a Kansas City concern, and it is being transported to the mines at Mount Sheridan. A reduction plant will be established this summer.

OREGON.

BAKER COUNTY.

A strike of rich ore is reported in the Gold Bug mine near Sumpter. The water-power plant is being hurried to completion. The strike recently reported from the Imperial is holding out well. Stoping has been commenced on the orebody while the drift is continued. The Highland mine, near Baker City, has begun operations with a full force, and the mill will be started up. The mine has been undergoing development for some time and there are now more than a mile of underground workings on this property. The mill has a capacity of 100 tons daily. Underground work will be confined to extending the main drift and completing raises.

SOUTH DAKOTA.

LAWRENCE COUNTY.

The Homestake Co. will enlarge the building of the slime-plant on McGovern hill at Deadwood. This building will now be made 210 ft. long, and it will contain a waste-water tank which will have a diameter of 20 ft. and a depth of 16 ft. The heating boiler is to be in the south end of the building.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence.)—The Pearl Consolidated Mining Co. has shipped 16 carloads of gold ore to the B. C. Cooper Co.'s smelter, at Greenwood, B. C. The ore averaged $12 to $13 a ton. In the stope above the bottom level, 165 ft. north of the shaft, the ore has improved during the past week. The crosscut from the drift southward on that lead has not reached the hanging wall, but the ore is also improving. The winze below the 330-ft. level of the Ben Hur is down 45 ft., and the ore is of the best average grade that was ever broken in the mine. Streaks of sulphide, rich in gold and silver, are becoming frequent.

Republic, May 19.

OKANOGAN COUNTY.

(Special Correspondence.)—The Copper World Extension mine is reported to have resumed work on the shaft, which will be sunk from 200 to 500 ft.—John Wentworth, superintendent of the Copper World, on Palmer mountain, has returned from Ohio where he secured funds for resumption of work. He will begin sinking on the vein, in pay ore, 800 ft. west of the Copper World Extension shaft, and will follow the ore. He has tents for a temporary camp, and will make permanent camp by building cabins during the summer. This company is planning an aerial tramway from Sinlahekin valley at the proposed spur from the Vancouver, Victoria and Eastern railway to the Q. S. mine. The Ruby Co., operating at the base of Mount Chopaca, has carried its raise in ore 200 ft. above the lower tunnel level. A five-foot vein of low-grade material overlies the rich streak all the way, the latter being 20 in. wide. The two streaks are broken separately, but the ore will be held for shipment.—At the Mountain Sheep mine, three miles north of the Ruby, the lower tunnel has 700 ft. to run to reach the vein opened in two upper tunnels. The ore is partly sulphantimoniate, but also carries galena in quartz gangue. Some of the former is rich. This company has ordered a 40 h. p. boiler and a compressor to be driven by water power, derived from Chopaca creek. Machine drills will be used.—An additional Wilfley table will be installed at the Prize mill, on the Similkameen river, near Nighthawk. A chute is being constructed from the mine to the mill. Some rich concentrate is being sent to the smelter.

Loomis, May 19.

WISCONSIN.

IOWA COUNTY.

Mining has taken a boom in and about the town of Mineral Point, where lead and zinc ores are being successfully sought, by the owners of town lots and farms, and by others. Drilling outfits are busy in back

yards and in all parts of town, as well as out in the country.—The Temby Mining Co. will put in boilers and pumps, unwater the shaft and prospect their ground. —The Gollmer Mining Co. has struck ore and will sink a shaft.—The Golden Rod Co. will prospect their property with a drill. This is an old mineral district which has been idle for many years.

BRITISH COLUMBIA.

Following are the ore shipments of the Boundary mines, in tons, for the week ending May 12: Granby mines, Phoenix, 16,257; Skylark, Skylark, 20. Total tons, 16,277. Smelter treatment for the week was: Granby Co., 15,184 tons.

The seventh smelter in Nelson district, the Pilot Bay, has blown in its first furnace and two more will follow. Transport conditions are improving. The total shipment for last week was 32,023 tons and for the year 628,945. Boundary shipped 24,262 tons, Rossland 5,978, and Slocan-Kootenay 1,613 tons. The Slocan shipments were: St. Eugene 559, Sullivan 500, Hunter V. 146, Silver King 308, Krao 23, Queen 19, Payne 18, Keystone 14, Cliff 10, Noonday 11, and Midnight 5. The Boundary shippers were: Granby, Mother Lode, Brooklyn, Emma, Sunset, Rawhide, Skylark and Providence. The Rossland shippers were: Centre Star, Le Roi, Le Roi No. 2, and Jumbo.—Work is being resumed on several of the mines of Rossland, the Velvet-Portland, Crown Point, Jumbo and the White Bear being among them. There is report of the resumption of the Cliff and Idaho.—At the Trail smelter they are building a new lead furnace, and starting a fifth copper furnace, making a total capacity for the output of copper between 1,300 and 1,400 tons daily, and 350 to 400 tons of lead. The refinery is turning out 50 tons of lead daily, and shipping the greater portion to Canadian consumers. The refinery is being enlarged to a capacity of 75 tons per day. New cranes and a 500 h. p. generator are being installed. The plant for the Huntington-Heberlein process is being enlarged by the addition of six converters. New transformers for the increased consumption of power are being put in, and a new blower has been ordered.

ONTARIO.

The Dominion Gold Mining and Reduction Co.'s works comprising a stamp-mill, cyanide and chlorination plant valued at $30,000, were burned a few days since. The works were erected by Powers and Linn, American mining men, who obtained a bonus of $10,000 from the town. They sold them to a mining company in which local people were interested, who sold out to the Dominion Gold Mining and Reduction Works Co. The property had been idle for some time.

In a statement issued to stockholders the net profits of the Nipissing Mines Co., of Cobalt, are given as $1,024,628. After deducting $400,000 paid to stockholders there remains a surplus of $624,628. These results have been produced from surface ores taken from less than ten per cent of the properties. It is expected that during the coming year the production of these mines will exceed that of the past year. The company owns 900 acres of Crown patent lands in the Cobalt mining district.

MEXICO.

CHIHUAHUA.

The discovery of a new lead-silver district in Cerro de los Lamentos, 60 miles east of Ojo Caliente, is reported. The ore is said to occur in limestone, the geology resembling that at Santa Eulalia, but no porphyry has as yet been found. The district is dry, the nearest water being 12 miles, but a limited supply can be obtained from wells sunk in the neighboring valleys. The Porvenir de Sonora Mining Co. have commenced the construction of a mill of 200 tons daily capacity, at their El Rio mine, 16 miles east of Pozo station in Sonora. The plant includes rolls, Huntington mills, concentrators, and a cyanide leaching plant. Thirty-five miles east of Carbo, the new milling plant of the Giroux Consolidated Mining Co. is approaching completion. The new smelter at Oaxaca is expected to be completed and blown in during the fall. A branch railroad, connecting the smelter with the Mexican Southern railroad is under construction. C. A. Hamilton is general manager. A late report is to the effect that Mazatlan is to have a large smelter for custom ore. The smelter for the Green Gold-Silver Co., at Guaymas, is under construction. Its initial capacity will be 100 tons per day The Parral Power & Reduction Co., which has leased the Parral Milling Co.'s mill, is about to start up the plant. The Parral district's production for April was 17,890 tons. Of this about 13,680 tons were shipped to the smelters and 4,210 tons were treated locally.

Books Received.

Compressed Air: This useful monthly publication comes out under a new management, Mr. W. L. Saunders having given the business management to Mr. P. F. Kobbe, Jr., and while himself remaining editor, he has delegated part of his duties to Mr. W. R. Hulbert, who is known to our readers as a contributor on matters pertaining to the use of compressed air and electricity. The magazine has always been a useful one, and we are glad that Mr. Saunders' multifarious occupation as chief of the Ingersoll-Rand Company will still enable him to conduct this periodical, with the aid of such efficient assistance. The issue for May is a particularly good one.

Metallurgical Calculations, by Joseph W. Richards, A. C., Ph. D., of Lehigh University, is an authoritative work which cannot fail to immediately interest the metallurgical operator and student. It takes up the chemical, mechanical and metallurgical features of ore reduction, handling them in a rational and thorough manner. Rule of thumb methods in this work, give place to scientific calculations and practice. The chapter on blast furnaces and their operation; hot and cold blast; converting, etc., are particularly interesting. Some space is also devoted to electric furnaces, electrolytic furnaces and electrolytic refining. Another valuable feature of the work is that portion given to condensation of metallic vapors, which refers more particularly to the treatment of zinc and mercury. Sent to any address, by the Mining and Scientific Press, upon receipt of price, $2. McGraw Publishing Co., publishers, New York City.

Trade Treatises.

We are in receipt of a most attractive catalogue of locomotive cranes, buckets and tubs, published by the Wellman-Seaver-Morgan Co., of Cleveland, Ohio. This catalogue is splendidly illustrated on calendered paper, and contains much valuable matter on the subject.

The Colorado Iron Works Co.'s new catalogue No. 9-A illustrates and describes its latest pattern of Impact Screen, giving drawings that show setting plans usually adopted for installing a number of screens in a mill. These plans are intended to show the adaptability of this screen to any required arrangement.

P. B. McCabe & Co., of 602 North Main Street, Los Angeles, Cal., have issued an illustrated pamphlet descriptive of the New Standard concentrator, manufactured by them. This pamphlet is well illustrated, the engravings showing the concentrator from different positions. Details of construction and method of operating are given in full, so that anyone who knows anything about machinery may set up and run it.

Commercial Paragraphs.

American Tool Works state that they will be prepared to resume business after June 1, at 109 Mission St., San Francisco.

The Wellman-Seaver-Morgan Company's Pacific Coast office, formerly at San Francisco, is now temporarily located at 220 Twelfth St., Oakland.

Francis Smith & Co., manufacturers of steel and cast iron pipe, have their offices and works at Eighth and Townsend Sts., San Francisco. They are uinjured and ready for business.

The Sullivan Machinery Company announces to its customers that Randolph D. Talmage is appointed local manager at Joplin, Missouri, succeeding S. A. Allison, who is no longer connected with this company.

H. C. Baker, formerly in charge of the Atlanta Office territory of the Crocker-Wheeler Co., has started for San Francisco where he will take charge of the Pacific Coast territory of the Crocker-Wheeler Co. with temporary offices at 2611 Broadway.

In addition to the offices of Allis-Chalmers Co., recently established in Oakland, at 906 Broadway, this company has opened quarters in the Atlas Bdg., 602 Mission St., "New" San Francisco, where its representatives may be found in readiness to transact business.

The Rix Compressed Air Co., 1222 Franklin St., Oakland, Cal., is erecting a 150 h.p. Cincinnati gear, Laidlaw-Dunn-Gordon compressor for the Pennsylvania mine, Nevada City, and two 500 h.p. compressors, same make, belted independently, to 500 h.p. Stanley motors for pumping gas to San Francisco from Martin station of the California Gas & Electric Corporation.

Personals.

B. B. Thayer is at Butte.

J. Parke Channing is at Butte.

James D. Hague is at Berkeley.

Charles Butters has gone to Chicago.

H. W. Turner is at Cottage Grove, Oregon.

R. M. Raymond, manager of El Oro mine, is at New York.

Charles E. Chapin is now at 2810 Grant St., Berkeley.

James W. Malcolmson has returned to El Paso from London.

J. H. Mackenzie is at Seattle, arranging for an expedition into Alaska.

Theodore Dwight has returned to New York from Guanajuato, Mexico.

G. Bronson Rea, editor of 'The Far Eastern Review' is returning to Manila.

Auguste Mathez, who returned recently from Australia, is now at Denver.

Franklin R. Carpenter is at Tinton, South Dakota, examining tin properties

A. P. Rogers is now in New York, but will return to California for the summer.

Harold Rickard is at Manchester, England, where he is to be married on June 9.

John Treweek is superintendent of the Sunnyside mine, near Roosevelt, Idaho.

W. B. Dennis and C. E. Ladd, of Portland, have been at Oakland during the week.

Forest J. Swears has returned to California after three years in South America.

R. T. Bayliss, chairman of The Exploration Company, London, is on a visit to New York.

W. W. Wishon, of Los Angeles, is examining mines at Davis Flat, in Fresno county, California.

Henry Lyne is in England on a holiday, following his marriage to Miss Eleanor Pope, of Philadelphia.

Robert T. Hill has returned to New York from Mexico. He is expected at San Francisco next week.

Edwin E. Chase, on his return to Denver from professional work in California, has gone to Butte, Montana.

C. H. Doolittle has been in San Francisco to purchase machinery. He returned to Salt Lake City this week.

J. B. Baker, superintendent of the Standby mine at Rochford, South Dakota, has returned to the mine from Boston.

Robert Rhodes is manager of the Mammoth Smelter, of the United States Smelting, Mining & Refining Co., in Shasta county, California.

J. B. Tyrrell has been retained as mining engineer to the Canadian Northern Railway and his office will be with that company in Toronto.

William H. Leffingwell, whose office was on the sixth floor of the Kohl Bdg., was one of the very few who were not burnt out. His home also was safe, being at Berkeley.

Charles Rhodes, manager of the Waihi mine, New Zealand, has been on a visit to Berkeley, where his son has graduated from the University of California. He has gone to London.

Simonds & King, as explained elsewhere, have dissolved partnership. L. M. King will have an assay office at 1311 Franklin St., Oakland. E. H. Simonds will practise as metallurgical engineer at 2842 Hillegas Ave., Berkeley.

George W. Maynard has gone to Sonora in the interests of the Illinois Development Co., of Chicago, who are operating mines at El Plomo, Sonora. He is consulting engineer of the company and P. W. K. Robertson is the general manager.

The Geological Society of Washington held a special meeting on May 18 to discuss the San Francisco earthquake. Messrs. F. L. Ransome, George H. Ashley, Ralph Arnold, G. K. Gilbert, W. C. Mendenhall, L. A. Bauer, and M. L. Fuller read papers on the subject.

F. W. Bradley has his office at his new residence, 2661 Broadway, San Francisco. At the same address are J. H. Mackenzie, the Bunker Hill & Sullivan Mining Co., the Oriental Con. Mining Co., the Mariposa Commercial & Mining Co., and the Nevada Con. Copper Company.

The Inland Printer, of Chicago, has offered its employment exchange free of charge to those looking for positions pending readjustment and full resumption of business in San Francisco, and the pages of that useful paper will be open to listing the names of those seeking positions in the printing trade, who have suffered from the recent disaster. This is a practical and generous offer.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 10 Bacon Block, Oakland, has official reports of the following United States patents issued to Pacific Coast inventors:

818,652.—**Soap Bar**—T. M. Anderson, Bellingham, Wash.
818,812.—**Fruit Packer**—F. K. Bartholomew, Campbell, Cal.
818,860.—**Horizontal Cylinder Piston**—F. L. Bates, San Francisco, Cal.
818,608.—**Suspended Railroad**—G. W. Brower, Santa Monica, Cal.
818,742.—**Sleeping Car**—P. P. Carroll, Seattle, Wash.
818,872.—**Brooder**—L. W. Clark, Petaluma, Cal.
818,940.—**Saliva-Ejector**—H. S. Davis, San Francisco, Cal.
819,006.—**Wave Motor**—F. M. Dempsey, Vallejo, Cal.
818,880.—**Fishing Reel**—Ernst & Patton, San Francisco, Cal.
818,954.—**Rail Crossing**—O. Gottschalk, San Francisco, Cal.
818,883.—**Cattle Guard**—F. V. Grimes, Centralia, Wash.
818,955.—**Door Securer**—J. R. Hall, Moro, Ore.
818,958.—**Carpenter's Tool**—Hause & Marlin, Enumclaw, Wash.
818,889.—**Basement & Like Ventilator**—P. H. Jackson, San Francisco, Cal.
818,541.—**Heat Conserving Apparatus**—H. Lang, Oakland, Cal.
818,542.—**Opera Chair Hat Rack**—F. D. Lanterman Los Angeles, Cal.
818,770.—**Butter Cutter**—E. J. Luhman, San Francisco, Cal.
818,843.—**Tube Expanding & Beading Tool**—W. McCormick, Hillyard, Cal.
818,776.—**Sand Blast Apparatus**—J. D. Murray, San Francisco, Cal.
818,550.—**Table**—S. A. Nichols, Los Angeles, Cal.
818,906.—**Measuring Instrument**—V. J. O'Connor, Bend, Ore.
818,552.—**Fruit Clipper**—H. H. Petty, Pomona, Cal.
819,024.—**Lock**—B. Phelps, Seattle, Wash.
818,559.—**Trace Buckle**—O. Rampendahl, St. Helena, Cal.
818,792.—**Attachment for Teams**—T. Schmieser, Davisville, Cal.
818,794.—**Pile & Like Clamp**—P. Sheridan, Berkeley, Cal.
818,799.—**Planter**—J. N. Taylor, Toluca, Cal.
818,930.—**Harness**—E. H. Yule, San Francisco, Cal.
819,967.—**Fender**—M. S. Aisbitt, Los Angeles, Cal.
819,969.—**Folding Furniture**—W. N. Anderson, San Rafael, Cal.
820,332.—**Irrigation Dam**—A. W. Applegate, Brawley, Cal.
819,838.—**Animal Trap**—P. Armstrong, Shelton, Wash.
820,336.—**School Furniture**—A. L. & G. H. Bancroft, Los Angeles, Cal.
819,843.—**Grading and Excavating Machine** — S. H. Bloomer, Seattle, Wash.
820,282.—**Electric Water Heater**—W. A. Brown, Oakland, Cal.
820,093.—**Bottle**—L. A. Calhoun, Oceanpark, Cal.
819,724.—**Rotary Engine**—A. H. Carpenter, Stockton, Cal.
820,097.—**Water Gate**—A. J. Collar, Yreka, Cal.
819,854.—**Sash Bar**—J. P. Comstock, Tacoma, Wash.
820,288.—**Briquetting Machine**—C. Demetrak, San Francisco, Cal.
820,101.—**Underreamer**—E. Double, Los Angeles, Cal.
819,986.—**Pump for Wells**—A. N. Ellis, San Bernardino, Cal.
819,747.—**Rotary Engine**—A. F. Ford, Colfax, Wash.
819,752.—**Steam Motor**—L. Gilmore, Jr., Colfax, Cal.
819,758.—**Rope Machine**—E. F. Hug, Elgin, Ore.
820,118.—**Amusement Apparatus**—F. J. Johnston, Sacramento, Cal.
820,203.—**Trousers Form**—Alice Jones, Dehesa, Cal.
819,775.—**Stove**—N. D. Loughery, Los Angeles, Cal.
819,902.—**Lock Nut**—W. C. Matteson, Stockton, Cal.
820,063.—**Selective Telephone System**—McKinsey & Nelson, Susanville, Cal.
820,064—**Selective Phone**—McKinsey & Nelson, Susanville, Cal.
820,006.—**Dumping Car**—A. Mieden, Seattle, Wash.
820,007.—**Pneumatic Cleanser**—A. E. Moorehead, Oakland, Cal.
820,122.—**Power Transmission**—Morrice & Grim, Sonora, Cal.
820,312.—**Saw Guide**—J. H. Perkins, Seattle, Wash.
819,925.—**Bale-tie Machine**—A. E .Rhoades, Elk Grove, Cal.

WESTERN GAS ENGINE CO., 547 Fulton St., San Francisco; cor. 3rd and Washington Sts., Oakland.

There are about 500,000 tons of mill-tailing lying near the bank of the Carson river, and east of the mouth of the Sutro tunnel, in Nevada, discharged from some of the mills which treated Comstock ore. This tailing is said to average $3 in gold and silver, but it also contains a large amount of mercury, partly native, and, probably, partly as chloride; copper sulphate, sodium chloride, silica, calcium carbonate, calcium sulphate, iron oxide and several other minerals, either native to the ore, or added in the milling operations. Numerous attempts have been made to treat this tailing by cyanide and otherwise, but the chemical and mechanical difficulties to be overcome have rendered it a somewhat uninviting commercial proposition.

EDITORIAL.

MAIL ADVICES from South Africa indicate that March was a splendid month in the history of the gold industry of the Rand. The output was 443,723 fine ounces valued at £1,884,815 or $9,141,352, exceeding the best previous monthly record by £51,500. There were 7,025 stamps at work on the Rand and 7,460 in the whole Transvaal. Among the laborers there were 78,676 Kaffirs and 49,877 Chinese. A notable increase in stamp-duty at several of the mills is credited to the use of tube-mills. The highest profit per ton earned on the Rand was 36 shillings, to be credited to the Robinson Central Deep mine. Nine dollars per ton is a handsome profit anywhere. In this case the working costs were 16s. 5d., say, $4 per ton. Therefore the ratio of profit was nearly 70 per cent.

OUR MELBOURNE CORRESPONDENT refers to a matter that calls for further comment. It appears that the firm of Bewick, Moreing & Co. is said to have antagonized labor in Australia and that for this reason the mines they control are in danger of incendiarism. We do not believe such a slander on the great Commonwealth of the antipodes and we trust that should it be even remotely possible, the authorities will realize the importance of thwarting such acts of criminal lunatics. When people are enterprising and independent they are apt to meet opposition, some of which may not be according to Hoyle, but we trust that those who have at heart the best interests of Australia will aid a firm so conspicuous for the stimulus it has given to the mining industry of the island continent.

OUR CONTEMPORARY at Johannesburg, *The South African Mines,* is waging a lively campaign against the labor system on the Rand and appears to have made good its assertions that a supply of efficient miners is lacking; that the wages of miners—both the good and the indifferent—are extraordinarily high; that labor, whether white or black, is wasted; that the supervision of mines is often incompetent and that mine managers are not encouraged to deal severely with these shortcomings. Many of these objectionable features are due to the high cost of living and the unhealthiness of work underground at Johannesburg. The cost of living is high because the administration is elaborate, railroad rates are excessive and supplies come from a great distance. Underground the conditions are unhealthy because of the dryness of the mines and the formation of sharp particles of quartz-dust injurious to the lungs. Centralization of management covering big groups of mines has tended to kill personal initiative and submerge the individual under the machine. We wish our contemporary success in its spirited campaign.

TO FLEE FROM EARTHQUAKES is about as philosophic as to try to dodge a thunderbolt and therefore we are not surprised that our immediate neighbors are so willing to remain in California. On another page we quote the observations of an authority upon British earthquakes, indicating that even the little islands set in the silver sea are subject to these disturbances. It has been said—on this side—that it needs an earthquake to perturb the stolidity of the British character, and obviously Nature is not unmindful of her duty. Here, in California, we realize that an occasional tremor is a small price to pay for a beauty of climate and a glory of sunshine that make life worth living indeed. In this connection we quote a brilliant young geologist at Washington who recently discussed the earthquake of April 18 in a scientific publication and was criticized for prognosticating further departures from California serenity. He says that he did "not predict bigger quakes but merely pointed out, what any intelligent man must realize, that earthquake probabilities in the future must be calculated from the data of the past. The recent great shock has probably relieved a strain that may have been 50 or 100 years in accumulating and which may be a century or more in again assuming dangerous proportions. Personally, I should be glad to take my chances in California, preferring the risk of the occasional earthquake to the inevitable visitation of our Eastern summer heat." All of which appeals to us as being true, so we expect to see our friends coming to California as of yore, to get rest, to obtain sunshine and to look upon the face of Nature where she is young and beautiful.

THE BOARD OF GOVERNORS of the New York Stock Exchange has passed a resolution stating that anyone having any sort of connection, or doing any business, with the Wall Street Mining & Stock Exchange "is guilty of an act or acts detrimental to the interests or welfare of this Exchange and any connection is hereby prohibited." All of which is impressive, but mistaken. It serves chiefly to emphasize the fact that the new exchange, largely devoted to the mining market, is doing an excellent business, for the price of membership has risen steadily of late, until it has reached $250, and of this we are glad, simply because the big Exchange has ignored mining. There are only two or three mining stocks quoted and of these Amalgamated, Anaconda and Homestake are all blind pools of an obviously dangerous kind, not one of which ought to be listed without disciplinary measures. At present mining shares are handled on the Curb—a peripatetic and rather absurd institution that divides a part of Broad Street with the cabs and lunch-wagons of the financial focus. Surely it is time that New York had a dignified and properly accredited mining exchange, either as a part of the Stock Exchange or as a separate institution. Whether the Wall Street Mining & Stock Exchange meets all the requirements, we do not know; but it appears to be a sincere endeavor to establish a mining mart.

METALLURGICAL DEVELOPMENT on the Rand rolls forward on tube-mills, and we are glad to be able to publish an important review of the subject by such energetic and capable engineers as the brothers Denny. They certainly exhibit a commendable example of proper professional spirit, for not only do they give frankly the results of several years of painstaking observation, but they also invite other metallurgists to visit the works under their charge and take such samples as may be required to check the stated figures of extraction. Messrs. George A. and Henry S. Denny have had to break trail in a metallurgical way, for they have been the pioneers in the introduction of tube-mills on the Rand, and they deserve credit for this initiative. It was prognosticated by them in July, 1903, that an addition to stamp-duty and an increase in extraction would follow the introduction of these re-grinding machines and now, nearly three years later, these statements have been made good. But it is the principle, rather than the particular device, that they advocated then, as they do today. Therefore it is interesting to note that they favor a trial with the grinding pan which has been successful at Kalgoorlie. Elsewhere the choice of machine will depend upon the character of the particular ore. At the Waihi mine, in New Zealand, the tube-mill has proved especially adapted

to fine grinding, so also at Goldfield, in Nevada, and El Oro, in Mexico. In regard to the filter-press which has been developed in connection with recent re-grinding methods, it appears that on the Rand the first experiments, made several years ago at the Robinson mine, provoked a discussion, the result of which was to condemn the use of this machine in that locality. In the case cited, at the Meyer & Charlton mine, the slime is not filter-pressed, the cyanide solution circulating right through the whole plant, as described by the Messrs. Denny. In the full paper some peculiar features affecting the precipitation of the gold on zinc-shaving are described, among them being the results from very weak solutions; it is also shown that the supposed bugbear of an abnormal amount of copper or zinc in the circulating solution is non-existent. The article we publish is an abstract; the full paper will be available in a couple of months.

Wrong Estimates.

Reports from mines often chronicle the agreeable fact that the ore is wider or richer than was stated in the original report on which the property was taken over by the company. The engineer who made the investigation for the buyer will write with pride that his moderate statements have proved below the mark. For instance, in the excellent report of the Dolores company, quoted by our London correspondent, it is stated that the stoping widths are greater by several feet than those given in the original valuation of the mine, and even the ore in the old dumps is richer than was stated at the time. This illustrates a curious—and it appears to us, mistaken—notion, prevalent in the mining community. It is not recognized as it should be, that under-estimates are no more laudable than over-estimates; the engineer's aim should be accuracy. As a matter of fact the best estimate is a careful approximation, and whether the margin of variation be above or below the truth, matters not at all—from an engineering standpoint, however variable the effect on the business of the mine promoter and speculator. For instance, the Dolores mine has turned out exceptionally well; it was examined by four mining engineers of the highest standing; their estimates differed and it is fair to say that the engineers who represented the purchasers gave the lowest estimates, and as these gentlemen had large financial backing, the other engineers who reported on the mine for the vendor, were placed in the position apparently of having drawn a long bow. They were all first-rate men so that no destructive criticism was ventured, but it is an amusing fact that the vendor's engineers were placed on the defensive. There was no more reason for this, than that the engineers who represented the other side should be regarded with suspicion. And now the purchasing company, through its consulting engineer and its directors, pats itself on the back for finding more ore than it paid for. The matter has both a humorous and a serious side. The humor is obvious; the bad effect on professional integrity is worthy of emphasis. It is not directly in question in this particular case, for we have no reason whatever to believe that there was any wrong-doing—that is, under-estimation of ore from bad motives—but, indirectly, the episode illustrates a wholly mistaken idea that an engineer is warranted in understating the value of a mine in order that his client may buy cheaply. That is misrepresentation, call it by any more pleasant name that you please, and it is unprofessional, if anything in the world is. An engineer who finds $1,000,000 of net profit to be won from the ore in a mine and states it at $750,000 in order to safeguard his reputation or to permit of a safe purchase by his client, is not one little bit nearer right than the other who, to help out a deal, states it at $1,250,000. Mining engineering is the application of science to mining, and science knows no such little tricks as making two and two into three, any more than into five. It is worth while to speak of this matter, for it has cropped up several times in recent years and has endangered the reputation of the profession before the public, more especially those who speculate in mines. We hold that an engineer who examines and reports on a mine should conduct himself as if he were appointed by a Court to appraise its value as between buyer and seller. It should make no difference which side engages him, his professional integrity ought to be as superior to the influence intended to affect his judgment, as it is superior to coarse bribery. This may be ideal, but perfect independence is always ideal—though none the less worthy of effort. It is our firm conviction that when the profession accepts this point of view, there will be more confidence in the judgment of its individual members and the public will be able better to distinguish between the professional man, who is to be trusted, and the financier, who has his own game to play.

The Home of the Survey.

Among the bills before Congress is one introduced in the Senate by Mr. Frank P. Flint, of California, and in the House of Representatives by Mr. James S. Sherman, of New York, the object of which is to provide a new building for the United States Geological Survey. We trust this bill will be passed, for it embodies the fulfillment of a pressing need. Those who have visited their friends on the Survey at their quarters in Washington are familiar with the crowded space and old-fashioned arrangement of the building that they occupy. The bureau gives permanent employment to 1,000 persons, and temporary field employment to nearly as many more. Of this total force about 600 men are engaged at times, and during all of every winter, on office work at Washington. The total floor-space available is only 105,670 square feet. Even the corridors are utilized for desks and map-cases. All engineers know how difficult it is to carry on drafting, compilation, and statistical work within narrow confines and how great a handicap it is to scientific men to use microscopes, examine mineral specimens and make chemical or physical researches in a poorly lighted room. Furthermore, the present building is so constructed that any delicate apparatus is affected by vibrations caused by the printing presses in an annex and at least twenty-five rooms in the main building are so dark as to require artificial lighting. The records stored within the present structure are worth $6,000,000 and as the building contains about 100,000 square feet of wooden partitions, it is obvious that there exists great danger from fire. Many of the records thus flimsily sheltered could not be replaced. It is desired to erect a modern building with a net available space of at least 150,000 square feet, exclusive of basement and halls; the cost would be $1,200,000, while the rental paid at present is $34,000 per annum, or nearly three per cent on the contemplated expenditure. We hope to see it duly authorized. The mining community is not without proper recognition for the splendid work done by the Survey, and while we have ventured more than once to criticize certain weak features in its administration during recent years, we take pleasure in emphasizing the urgent need for facilities such as are required for the comfort of its scientific corps and the preservation of its invaluable archives.

By the Way.

In a recent issue of 'The Nineteenth Century,' there is an interesting article on 'Earthquakes in Great Britain.' We quote a portion of it:

At places near the center of disturbance, the first sign of the coming earthquake is a low sound like the sudden rising of the wind. Almost immediately a faint trembling begins, such as is felt on a railway platform when an express train rushes by. Rapidly this increases in strength, the sound becomes louder, more rumbling and grating in character, and resembling that produced by the rapid passage of a traction-engine or a heavy motor-car. It is a sound so deep as almost to be more felt than heard. Then, after the lapse of four or five seconds from the start, the tremors merge into sharp rapid vibrations, accompanied by loud explosive crashes in the midst of the rumbling sound. These may last for two or three seconds, after which the vibrations shade off again into tremors, the sound becomes a mere rumbling and finally all movement ceases, the sound dying away as a low monotonous groan like the last roll of very distant thunder. Farther away, at distances of from 50 to 100 miles from the center, the phenomena are much simpler. There is no change in the nature of the sound, which merely increases in strength with the tremor, and then both die away together. The movement is, however, less rapid and jolting, and more like that felt in a carriage with good springs traveling over an uneven road.

Nineteen out of every twenty earthquakes in this country are fairly represented by the above descriptions. The remaining earthquakes are somewhat more complex. The shock consists of two distinct parts separated by an interval of two or three seconds, each part being similar to the shock of a simple earthquake. In some, the two parts are connected at places near the center by a weak tremulous motion, which, at a short distance, becomes imperceptible; in others, the interval between the two parts is everywhere one of absolute rest and quiet. The parts generally differ slightly in duration and intensity, and occasionally in the nature of their vibrations. To earthquakes of this class, the name of 'twin' has been given, because, as will be seen, the double shock is due to two distinct impulses resulting from a single generative effort.

The strongest earthquakes in this country are just capable of producing slight damage to buildings. Others are strong enough to overthrow ornaments and vases, or to make pictures and chandeliers swing, to give a perceptible movement to the observer's seat, to make doors, windows, etc., rattle, or, finally, to be just perceptible to a person at rest. The waves of any earthquake, as they radiate outward from the origin, pass gradually through these different degrees of intensity. Knowing the degree at a large number of places, it is possible to draw on the map of an earthquake a series of isoseismal lines, or lines of equal intensity. Rough though this scale of intensity may be, it would be difficult to over-estimate the service which it has rendered in the investigation of earthquakes.

In any earthquake, the outer isoseismal lines are nearly circular in form, while the inner curves are elongated (approximately in the same direction), the innermost curve of all being as a rule the most elongated. It is, however, when considered in connection with the geological structure of the districts that the significance of these elongated isoseismal lines becomes apparent. Their longer axes are then found to be parallel, or nearly so, to the axes of the great crust-folds of the underlying rocks. The initiation of these folds dates from long-past geological ages, and their formation has proceeded slowly and gradually ever since. In close connection with the folds, however, are nearly parallel and perpendicular systems of faults or fractures, along which movement takes place intermittently, the crust on one side advancing over that on the other by a series of slips, rather than by imperceptible creeps. When we consider that these faults are often many miles in length (two, for instance, cross the whole of Scotland), and that the total displacement may amount to thousands of feet, even to miles, when we think, further, that in each individual slip the crust may not advance by more than a fraction of an inch, though it may be by several feet, we can realize, though but dimly, the enormous number of displacements that must contribute to the growth of a great fault. At the same time, if we consider the mass of the rock that may be subjected to one of these slips and the friction that must thus suddenly be brought into action, we can understand how the resulting vibration would produce a shock that may be as weak as the faintest tremor felt at Comrie, or, on the other hand, as mighty as one of the great convulsions that have devastated Lisbon or Calabria, or ruined the coasts of Chili and Japan.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

It is customary to lay T rails in mines with the joints between ties, and not upon them. The rails wear more evenly when this is done.

There are four types of flume construction: The V type, the rectangular, the vertical side with inclined bottom, and the semi-cylinder. The latter is usually made of half-round steel sections.

The lessee of a mine has a right to all of value that may be in the dump created by his mining operations, unless the lease stipulates otherwise, but the right ceases upon the termination of his lease.

Nickel of high purity—99.2 per cent—is produced by electro-chemical methods, but there is no demand for nickel of such purity in competition with the metal produced by other and less expensive methods.

The pressure of water is equal in all directions. On the face of a dam the direction of pressure at any point is normal to the face of the dam at that point. If the face of the dam be vertical, the pressure of the water on its inner face is horizontally outward.

Where tailing or dump-rock is left on the land of another, this detritus of mining operations becomes the property of the landowner, who may convert it to his own use if he so desires, or he may sue the owner of the mine or mill producing it for damage, if any result to him.

Wrought iron, not only because of its freedom from manganese, but because of its very defect of being laminated by the presence of cinder, is more ductile than mild steel under certain special conditions of use, such as for rivets and horseshoe nails, many of which are made from it.

The occurrence of fluorite in ore is not indicative of the presence of telluride of gold, but rather incidental to it, as in the Cripple Creek district of Colorado, and in lesser amount in the Black Hills of South Dakota. Fluorite is of frequent occurrence in lead and zinc mines where no tellurides are known to exist.

The principal objection to the general introduction of the metric system comes from manufacturers, who claim its adoption would necessitate changes in all existing gauges and standards of measurement in America and England, particularly in sizes of steel and iron plates, bars, wires, etc., and in the standardized tools employed in their use.

The compression of air always develops heat, so much so in fact, that, if a mass of air is compressed to one-fourth of its original volume, its temperature will be raised to 376° F. if no heat is allowed to escape. Since the air, thus compressed, is allowed to cool down to the temperature of the surrounding atmosphere before it is used, the mechanical equivalent of this dissipated heat is work lost.

Concerning the life of a wire rope on an aerial tramway: In one instance a new rope lasted but three months. It was replaced by another first-class steel rope which has now been in continuous use for three years and is apparently still in good condition. In another case, a rope carried 1000 tons daily during a shift of seven hours and was worn out at the end of fifteen months.

Free gold often occurs in the foils of mica schist, particularly when silicious and of a dark purplish-brown color; but deposits of this sort are usually merely zones of mineralization which are limited in both horizontal and downward extent. Well-defined veins in mica schist are as likely to be permanent, however, as those occurring in any other formation, particularly when the vein occupies a well-defined fissure cutting across the schist.

The California courts have held that in case of a cross-lode location the junior locator may pass through the ground of the senior locator, but must turn over to the senior locator all the ore removed within the vertical planes determined by the latter's claim-lines. Those portions of the junior locator's claim lying outside the boundaries of the senior claim may be worked by the junior locator without interference from the senior locator.

As a material for making the better classes of tool-steel, by re-melting, by the crucible process, wrought iron is preferred to mild steel both because it can be made freer from certain elements, especially manganese, which are here undesirable, and because the crucible steel made from it is, in the opinion of the best judges, better than that made from mild steel, even if of like composition, though why this is so has not been convincingly explained.

The initial step in the development of the electro-chemical and electro-metallurgical industries was the refining of copper electrolytically. These branches of scientific industry have grown rapidly during the past decade. Electrolysis is now employed in the manufacture of metallic sodium, caustic soda, sodium peroxide, bleaching powder, zinc chloride, cyanide and other salts of the metals. The manufacture of aluminum has grown into a large industry both in the United States and in Europe.

There are nearly seventy establishments in the United States, Italy and France producing calcium carbide, the aggregate output being 90,000 tons annually. Both the output and consumption of this material is increasing. Acetylene lamps are both useful and satisfactory in mines. No class of portable light is better for shaft inspection or for the examination of high backs in stopes, caved workings, and other places beyond the range of ordinary lights such as are usually employed in mines.

Felsite is generally ashy gray in color, but is also occasionally brown, reddish, green and even black, due to the occurrence of innumerable dark colored inclusions. It occurs from small veins up to great mountain masses, and zones of fracture in the rock are often found to have been mineralized sufficiently to constitute ore deposits of commercial value. Felsite is often difficult to distinguish from rhyolite, much of which it resembles in physical appearance.

The greater number of ore deposits and veins occurring in the Great Basin region are found in igneous rocks, both intrusive and volcanic. These include the older diorite, diabase, quartz-porphyry, granite, etc., and the andesite, rhyolite, trachyte, and some less common effusive rock types. Ore deposits are also found in the sedimentaries, particularly limestone and quartzite, but usually at or near the contact of these sedimentaries with intrusive dikes and masses.

Corundum is the hardest known mineral next to the diamond, being nine in the scale of hardness, in which quartz is seven and the diamond ten. Different crystals and pieces of corundum vary somewhat in hardness, though only slightly. The blue sapphire is the hardest, the ruby being a little softer. Emery is a granular corundum, in which the grains are mixed with magnetite or hematite. In size the grains of corundum vary from those too small to be distinguished to those which may be plainly seen. Emery has a metallic to submetallic luster, clean corundum being adamantine.

Cinnabar occurs in a great many places in California, but comparatively few of these occurrences are of commercial importance. The greater number of these are in the Coast range region, but there are several localities in the foot-hills of the Sierra Nevada the most noted being near Latrobe, in El Dorado county. Another occurrence is known near Horseshoe Bend in Mariposa county, in association with gold in a quartz vein. A small amount of cinnabar is found with hematite about two miles from Copper Basin, 13 miles southwest of Prescott, Yavapai county, Arizona. It is not worked and but little developed.

The rate of increase of production of the iron blast-furnace has been extraordinary. In 1863 a daily production of 50 tons per furnace, and, in 1880, one of 115 tons was unusually large; but in 1898 one of the Duquesne furnaces made 711 tons per day, and the four furnaces of the plant were making regularly 2,200 to 2,300 tons daily, a rate half as great as that of the United States furnaces collectively in 1870. Ohio No. 2 furnace at Youngstown, Ohio, has made 806 tons of bessemer-pig iron in 24 hours. The increase since 1880 has been brought about—not chiefly by the use of larger furnaces (although the hearth is made wider than formerly), but by providing very powerful engines and hot-blast stoves, and it has almost forced the adoption of automatic methods for handling rapidly both the raw material, the cinder, and the pig metal of the furnace.

The recent eruption of Mount Vesuvius has attracted the attention of the entire world, but as stupendous as it was, Vesuvius is a volcano of the second, or even third class, as compared with the great volcanoes of the Pacific coast, active, dormant and extinct. There are a score of volcanic cones in the region included in the Shasta and Lassen Peak section of California, rivaling Vesuvius in magnitude, while Shasta and Lassen are of comparatively prodigious size. The most recent volcanic eruptions in California are those of Inskip Hill, near Payne creek, Tehama county, and the cinder cone ten miles east of Lassen peak in Shasta county. At the latter place, pine trees are still standing in the ashes which fell about the vent, indicating the recent date of this eruption.

Where quartz lenses occur in mica schist, they follow a definite strike, usually at a slight angle to that of the formation. Frequently these lenses overlap at their ends, the distance between them generally having a direct relation to the size of the successive deposits, the distances being roughly proportional to the size of the individual lenses of quartz. That is, where the several successive lenses are large, the distance between them is greater than where the lenses are small. Both the large and small lenses are produced by similar causes, the amount of the stress usually determining the extent of the crumpling of the schists, which in turn pre-determines the size, but not necessarily the richness of the ore-shoot.

Lime is calcium oxide. In nature calcium occurs most commonly as carbonate (calcite) or as sulphate (gypsum). Calcite is crystallized calcium carbonate. Before the blowpipe it becomes calcium oxide, and does not crumble. Aragonite is also crystallized calcium carbonate, but crumbles before the blowpipe flame. Common limestone is calcium carbonate, and effervesces in cold hydrochloric acid. Much marble is dolomite. Dolomitic limestone effervesces slightly or not at all in cold hydrochloric acid, but readily if the acid be heated. The mineral should be pulverized. Limestone treated with hydrochloric acid forms calcium chloride. On the addition of sulphuric acid, calcium sulphate is precipitated.

If it costs $4 to smelt a ton of self-fluxing ore worth $8 per ton f. o. b. at the smelting works, we have a profit of $4 per ton. If the ore needs, for example, one-fourth ton of iron ore and one-fourth ton of limestone (as may be calculated beforehand) then the returns would be as follows:

Smelting 1½ tons material of the charge..	$6.00
¼ ton iron ore @ $4.....	1.00
¼ ton limestone @ $1.....	.25
Total cost	$7.25

Leaving but 75c per ton profit to the works treating such an ore—to say nothing of losses in the slag and as flue-dust—this would give a narrow margin indeed! Figured on the same basis for a silicious ore, needing one ton each of iron ore and limestone to the ton of ore, we shall find the total cost to figure out $17 and, at the same time, the works would put through but one-third as much ore as if it had been self-fluxing.

Until lately, the cast iron for the bessemer process has nearly always been allowed to solidify in pigs, which were next broken by manual labor and re-melted at great cost. It has long been seen that there should be a great saving if this re-melting could be avoided and the 'direct metal,' that is, the molten cast iron direct from the blast furnace, be treated by the bessemer process. The obstacle is, that, owing to unavoidable irregularities in the blast-furnace process, the silicon and sulphur of the cast iron vary to a degree and with an abruptness the bessemer process can hardly tolerate. To ensure the constant quality of the cast iron thus to be used, Capt. W. R. Jones invented the mixer first put into operation at the Carnegie Steel Works. This is simply a great reservoir like a reverberatory furnace into which successive lots of molten cast iron from all the available blast-furnaces is poured, forming a great molten mass of 200 or more tons. This is kept molten by a small flame playing over it. The successive lots of cast iron, thus mixed and arranged, are drawn off, as they are needed, for conversion into steel at the converter. This device not only makes the cast iron much more uniform, but also, by a curious reaction, removes much of the last traces of contained sulphur.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

SOME PRACTICAL HINTS.

The Editor:

Sir—The man whose business brings him in contact with actual mining operations, whether in the capacity of mining engineer, manager, superintendent, or surveyor, or even a casual visitor, cannot fail to note the various methods of construction and maintenance of the main openings.

If the mine is worked through an adit (I prefer the word 'adit' to 'tunnel' and believe it is the better term for an underground opening that has but one end at the surface) the first thing a practical miner notices is the timbering, if any, and the condition of the track, footway and water-ditch. It is not unusual to find such an opening timbered in the most nondescript manner, the sets placed at irregular distances from each other and no two in line, giving one the impression that the timbers are framed and set to conform to the ground instead of taking out the ground necessary to allow of timbers of a uniform size and length being placed in line with each other. It may be well to state here that the operations of our large companies, driving big openings in a well-ordered, systematic manner do not come within the purview of this article.

The reason, no doubt that so many adits are tortuous and crooked, is the fact that many of them were originally driven by poor prospectors who, without adequate funds at their disposal and working under extremely adverse conditions, were compelled to sacrifice symmetry of detail in their effort to force the opening ahead as quickly and cheaply as possible. Then, too, in driving a prospect adit it is only natural for a man to follow the line of least resistance, which policy is bound to cause him to avoid a hard 'knuck' on one side and work the softer material on the other, should it exist there. Another, and perhaps a more potent reason for crooked openings is that where the work is done on the vein itself (and that is the place for a prospector to do it generally), the windings and turnings of the vein will determine the course of the drift. It is generally the practice to follow along one of the walls or both, if the width of the vein will admit of it. It is easy, therefore, to see why the original prospector's drift is such a crooked, irregular passage but I cannot see any reason whatever for the manner in which many of our regular operators construct their main drifts and cross-cuts.

It is about as easy, under usual conditions, to drive a drift right as wrong and the latter makes for a great increased cost in subsequent operation and maintenance. Let us now try and prove this. Imagine an ideal case; suppose a drift in which a turn occurs at almost every set; no particular attention is paid to uniformity of grade; sills are placed on the bottom; if there is not quite room enough for the sill to go in, it is placed out of line, or perhaps the miner prefers to operate on the sill with an ax rather than bestow his energies on the interfering ground with a pick or gad, or drilling a 'plug.' Let us see now what happens.

The timbers are placed any way they can be got to stand; if collar-braces or girts are used, one or both must be cut specially for the set, the regular lagging will not suit, they will be too short, requiring longer ones to be cut, or they will be too long, making it necessary to cut them, or else have them overlap those on the preceding set.

Now for the floor. The sill, being set close down to the ground, causes the water, if present, to make a pool until it flows over the sill, or else, if there is room, to pass around the end of it. The argument relating to the lagging overhead, is applicable to those on the floor. On account of the turns of the drift, when the track is laid it will be found to consist of a series of reverse and compound curves, all more or less sharp, making the track extremely difficult to run cars over and costly to keep in shape. If no provision is made for a water-ditch and water is encountered, which is almost sure to be the case, sooner or later, it must flow over the track and running boards, making traffic along the drift disagreeable at all times, if not impossible; the carmen are splashing through water all day long and the car-wheels require constant lubricating; and even then they will fail to run anywhere near as easy as they should.

Another result of continual change of course and a lack of alignment of the sets in the drift is the fact that where it is run through ground that will subsequently be stoped, it will prove extremely annoying and expensive, should it be necessary to erect square sets above the drift, to try and make them conform to the timbers in the drift below; indeed, the best way I know to start the stope-timbering where such conditions exist in the drift as I have hinted at, is to lay another set of sills on the first floor and place them as nearly as possible at right angles to the strike of the lead, thus rectifying on the first floor what should have been done on the sill.

We will now consider another way of doing this work. Suppose a drift is being run on the vein. The procedure will be similar whether hand or power-drills are used. Of course, if the latter method is employed, the face may of necessity be kept well ahead of the timbers, but the ultimate condition of the drift will be the same in both cases. If the floor of the drift is kept down at least six inches below the point at which the bottom of the sill will rest, a good water-ditch will be secured, quite adequate for all ordinary conditions. Two 3 by 6-in. (or wider) stringers may be laid along these sills, spaced say 12 in. apart, the sides of these stringers being each 6 in. from the center of sill and spiked to it. A 2 by 12-in. plank is laid between these stringers, which just fills the space; this is not spiked but merely laid in there and may be removed at any time to inspect or clean up the ditch underneath. The space between the stringers and the sides of the drift may be covered with regular 2-in. plank lagging. The T rails are laid on the 3 by 6 stringers and spiked with reverse-point rail-spikes. This arrangement places the rails one inch above the regular floor, keeps them clear of any rubbish or debris that may happen to be on the floor and makes a good substantial track, as the rail is supported along its entire length.

Whenever it becomes necessary to make a turn in the drift it may be done in several ways, but there are only two that appeal to me as being satisfactory. It may be done by making the entire change with one set, shortening one girt or lengthening the other, or both. If it is merely desired to throw the drift to one side or the other without changing its general course, it may be done by cutting back for a three-post sill and making a side-jump of one whole set; then, when the timbers are to stand on this sill, a double-length cap is placed thereon and the set lagged over in the usual manner, or the three posts may be placed and regular caps placed thereon, and after the face of the drift has been driven ahead sufficiently the center post may be removed, a false cap put under the two regular caps and butt-end posts placed under this at any convenient points, taking care to block up the sill directly below these posts, which will allow the track to be brought around with the largest possible curve. I prefer the double cap in the first place, however, as it finishes the work at once and avoids lowering the back at this point, which is unavoidable if the extra false cap is used, beneath the regular timbers. Whichever method is used, it will be seen readily that no trouble will result when working the first floor, as the regular sets will fit in at that point.

If a cross-cut or prospecting drift is to be run and no timbers are required to support the ground, the rails may be laid on ties; a ditch is made for the water and maintained at the side between the ends of the ties and the side of the cross-cut. Even in this case it would be better to use sills and stringers, unless the cost of lumber is prohibitory, because it makes a cleaner and better track and the ditch, being covered, would not become blocked so readily. Another advantage of the sill and stringer method is that if ore is encountered at some inside point, the grade is established and no change of grade at the bottom of the drift or the rails will be necessary, whereas if the ditch is carried at the side, when we come to the point where we wish to place it under the sills we shall be compelled to raise the track in order to carry it up to the sills and stringers.

I do not wish, Mr. Editor, to encroach on your valuable space with a too lengthy dissertation on a subject which may be considered as of only minor importance. The reason for my writing this at all is the fact that my observations have led me to wonder why so many men who claim to be capable mining men can be content to worry along in such a makeshift manner as they do, apparently under the impression that they are saving money when, as a matter of fact, they are really losing financially, to say nothing of the discomforts to which all concerned are subjected. At a mine I once visited, not a thousand miles from San Francisco, a custom prevailed to take out enough ground to lay the sill flat, then cut out enough of the center of the sill to allow the water to flow. After a while the drift began to take side-pressure and the sills, weakened by this chopping and the pressure against the bottom, buckled up in the center, throwing the track up with it, thereby entailing a large expense for repairs and being a constant source of annoyance.

In the mining business, as in every walk of life, the successful superintendent is he who is willing to pay attention to details; who is ever on the alert to utilize better methods; who is quick to grasp whatever may prove to be of advantage and who refuses to cling to any method of working that is obsolete. A man will naturally cherish his own ideas of working, but when he sees somebody else's scheme that is evidently superior to his own, if he is wise, he will change his tactics and adopt that which will make for better results. It is often the case that first cost is allowed to determine the modus operandi. This consideration should not be permitted to have undue influence. It is well to look ahead and, as nearly as possible, compute the whole cost and whether or not it will be cheaper in the long run to pursue an apparently cheap, parsimonious policy, saying "that's good enough" when the subsequent cost of repairs and maintenance may far outweigh the questionable saving at the outset.

Butte, May 24, 1906. EDWARD W. RALPH.

Extraordinary Prices for Tin.

The 'Iron Age' has the following interesting comment on a striking feature of the metal markets:

When a commodity used so widely throughout the world as pig tin advances by leaps and bounds, as this metal lately has, the fact is worthy of more than passing attention. A month ago sales were made at 38½ cents, a week ago at 40 cents, while in the first week of May the high price of 43½ cents has been realized for 5-ton lots. The metal has advanced over 50 per cent in the last year, as one year ago it was sold at 28½ cents. In spite of these high prices the consumption is keeping up and dealers in the metal report business brisk. This is to be expected, as for some time past consumers believed the market too high and consequently bought only as their immediate needs warranted, with the result that they are now compelled to re-enter the market. This hand to mouth consumption, of course, adds many elements of strength to a market already in an excellent statistical position. In fact, prices in the United States today are nearly one cent above import cost, indicating clearly the premium which spot metal commands.

At present prices importers generally are reluctant to make large commitments, as they fear the market may drop away from them while supplies are on the way from Europe. The advance of the last few days is partially the result of speculation and overbuying of both spot and future supplies by foreign operators. It is a significant fact that the last advance in London of nearly £25 has been brought about on little or no specific information. The London market is in such a state that those who are in a position to buy are afraid to do so, fearing that the market may drop, while those who believe that lower prices will be the rule are reluctant to sell because of the ease with which this last advance of £25 was made. The bull movement which has been running for the past six months is generally attributed to two of the leading operators in London.

There is no gainsaying that statistics are favorable for higher prices than a year ago, and in this connection the accompanying table showing the world's consumption per year and visible supply on the first of April of each year is interesting. It shows that in 1900 the visible supply amounted to 21 per cent of the yearly consumption, while on April 1 of this year the percentage had fallen to an amount that is 12 per cent of last year's consumption, with the consumption of 1906 promising to be greater than that in 1905.

Consumption and Visible Supply Compared—Gross Tons

	1900.	1902.	1903.	1904.	1905.	1906.
Consumption	77,200	87,970	89,000	92,400	90,550	.....
Visible supply	16,191	15,596	15,987	13,695	13,063	11,104

Another factor of interest is that the opening of new mines of the Straits Settlements has been discouraged by the Government and the old workings are not as rich as formerly. The political situation in South Africa, too, has a further bearing on the supply, as there has been a migration of coolies now laboring in the Transvaal, which naturally makes coolie labor higher in the Straits. In spite of the prospect for higher prices as far as the statistics are concerned it is significant that some of those well informed about the situation, who have been consistently holding out for higher prices during the past year, are now decrying the wild scramble for the metal and express the belief that while higher prices may be the rule, still the present sharp advance is hardly justifiable. There is, too, the familiar fact, borne out by history, that when a commodity seems to be rising in price beyond all reason either new supplies are discovered or some substitute is found.

Hydraulic Mining in a Cold Climate.

Written for the MINING AND SCIENTIFIC PRESS by J. P. HUTCHINS.

Hydraulicking, most spectacular of all mining methods, and that which, more than any other, illustrates most aptly the triumph of mind over matter, has a large following among those who are impressed by scenic effect rather than by economic reason. The idea of "harnessing" and "controlling" water, and of using it to tear down gravel-banks has a powerful fascination. Thus, it is not surprising that all through the Alaska and Yukon Territories, attempts have been made to conduct hydraulic mining, where unfavorable physiography and hostile climate are but two of a number of formidable obstacles.

Some further consideration of the fitness of this method of mining in a rigid climate is timely. A renewed interest in hydraulic mines, which the possible resumption of hydraulicking in California occasions, brings this branch of the industry into greater prominence than for many years.

After the discovery of gold in California, in 1848, there was an enormous stampede to the goldfields and over 100,000 diggers were soon at work. The first to be exploited were the shallow deposits in the beds and on the banks of streams and rivers. As these were worked, and the miner followed the pay-streaks, deeper gravel on the flanks of hills was uncovered. Water was ditched to them and 'shoveling-in,' 'ground-sluicing' and 'booming' were practiced, but it was soon noticed, particularly where the gravel was at all hard, that the sluices, whether in rock cuts or wooden troughs, could carry much more material than was being fed to them. More men at high wages were employed to remedy this condition. To get gravel to the sluices by a cheaper method, became the problem.

All the other branches of placer mining, except subaqueous working, were known and had been practised for centuries. Water under pressure had never been used to excavate as well as to transport material. It was the combination of an extremely favorable physiography, permitting water to be conducted by short ditches at an elevation above the gravel, and a large amount of Yankee ingenuity, that resulted in the invention of hydraulic mining in California only four years after the discovery of gold.

It was begun with a rawhide hose and a wooden nozzle, but it developed quickly until finally nozzles of nine-inch diameter were used, pressures over 400 lb. per sq. in. were withstood by steel pipes of large diameter, and volumes equal to 90 sec. ft. were projected in a single stream under the easy control of one man. Thus mining could be done on an immense scale and gravel yielding only three cents per cubic yard could be worked at a profit Under exceptional conditions, even this low figure has been surpassed in cheapness, notably at Flint Creek, Montana, where gravel yielding one and a half cents has been washed at a profit.

Hydraulic mining is really a problem in earthwork. Auriferous material is excavated and moved from one place to another by water power; during its transit, the gold content is extracted. Hence, a deposit containing gold from top to bottom in payable quantity, must be situated where topographic conditions permit the installation of sluices on sufficient grade, low enough to tap the alluvion, but also high enough to permit ample discharge for the tailing. Water must be obtainable in large volume for a considerable period each year, under high pressure, to do the work of excavating and transporting.

The ideal hydraulic gravel is that which is rich, friable, clean, rounded and fine, with its gold content disseminated throughout its vertical section, occurring in large quantity in good environment, on a bedrock possessing sluice-grade near good dump ground and with ample water under heavy pressure. The gold is most easily saved when clean, amalgamable, fairly coarse, and not penetrating deep into the bedrock and its crevices.

Topography is most important in hydraulicking. Its bearing is four-fold: First, it governs the sluice-grade, which affects the carrying capacity of the sluice. Second, it determines the position and length of the sluices. Third, it furnishes good or bad dump. Fourth, it permits or prevents the application of cheap water under sufficient pressure. It was favorable topography, in conjunction with gravel of only moderate richness, that made hydraulic mining so remunerative in California.

The obstacles to successful hydraulicking are various. They include, of course, any characteristics antithetical to those mentioned above. The most common difficulties are those due to bad topographic conditions, which, while not preventing a large supply of water under pressure, are such as to cause deficient grade and dump. There are hundreds of millions of cubic yards of gravel on the western flanks of the Sierra Nevada in California unworkable for this reason. Consideration of the various northern placers will indicate numerous difficulties.

Hydraulicking in Klondike.—The northern alluvion most interesting from a miner's standpoint is that of Klondike. They may be grouped in order of deposition, as was done by R. G. McConnell (Prelim. Rep. on Klondike Gold Fields Geol. Sur. Canada, 1900). His classification was: (1) White Channel or quartz drift. (2) Its associated overlying yellow gravel. (3) River gravel. (4) Terrace gravel work. (5) Valley gravel. While the foregoing differentiation is genetic, another one which can be made, according to the situation of the gravel, relative to the present streams, is more useful to the hydraulic miner. It is as follows: Stream gravel and bench gravel. The first includes all alluvion, in the creek and river-beds; the second all alluvion, whether a few feet or several hundred feet. above the creek-bed. Thus all except valley gravel, under Mr. McConnell's scheme, are grouped under one head. This is entirely arbitrary, but its fitness will appear later in this article.

Stream Gravel.—On account of peculiar physiographic features, which make the Klondike district one of topographic isolation, water is too limited and costly to work the stream gravel by hydraulic methods with elevators or other modified methods. No hydraulicking worthy of note has ever been conducted in the creek-beds; their exploitation must, of necessity, be carried on in other ways. It may be interesting to note, in passing, that an ample supply of cheap water would have entirely modified early-day mining methods and costs in Klondike. It would have made cheaper mining possible, and resulted in a larger product and profit.

Bench Gravel.—These deposits may well be grouped under two heads according to their elevation above the creeks; thus, there are low and high benches. The low benches are peneplains of the creeks; the high benches are remains of the Pliocene creek-gravel.

Low Benches.—These are workable by hydraulic methods where topographic conditions furnish grade for sluice and dump for tailing. They are of small area, shallow section, and infrequent occurrence.

Overburden.—The gravel deposits are usually overlaid by muck, sometimes over 50 ft. deep; this material is solidly frozen, it thaws slowly and is a most serious impediment to mining. Where a large volume of water flows over it constantly, it seems to thaw rapidly; in reality, however, it yields but slowly to the warming influence of sun, air, or water. It is a semi-decomposed vegetable soil having a large content of interstitial ice, and, at times, it contains solid strata and lenses of ice, at varying depth from the surface. An admixture of sand, and, though less frequently, gravel and sand in regular strata, indicates that this material was laid down alluvially, or possibly, diluvially after unusual floods. Like straw and other vegetable matter, it is an extremely poor conductor of heat. It may be ground-sluiced cheaply, when it occurs as an overburden on stream-gravel and the creek can be made easily to cut through it. 'Muck' has low gravity and is thus easily washed away on flat grade when thawed, but where it occurs as an overburden on bench gravel, and is of any depth, it reduces the duty of the miner's inch very materially.

Usually the low benches are properly workable by drifting. A shallow stratum of pay overlaid by a deep, barren overburden, is the reason. There are conditions where hydraulicking may be properly applied, but a modified method, including ground-sluicing the muck with water discharged over the face (thus causing numerous cuts with large thawing area), has proven best.

Character of Gravel.—This, like stream gravel, is composed of small, worn boulders of schist, and of subangular quartz pebbles and sand, all of which were derived by erosion of the country rock and its enclosed veins, and of the higher bench gravel—called the 'White Channel' because of the color of the prevailing content. It usually lies on a blocky, uneven bedrock, into the crevices of which gold sometimes penetrates in such quantity as to make it worth while to mine it to a depth of six feet. The richness is sometimes equal to that of stream-gravel, where for a whole claim, with a depth of about 15 ft. an average yield of about $20 per cu. yd. has been secured. Needless to state, there is little gravel of such value remaining and the hydraulic miner must rely upon material too poor for drifting and not having too heavy an overburden, or gravel that was wastefully exploited in the early days and still possesses workable value and not much overburden.

Cost of Hydraulicking.—This will be high; small deposits of shallow section (making necessary much rock-cutting for sluices and frequent moving of the machines), muck overburden, rough blocky bedrock, and the frozen condition of gravel, are the unfavorable factors.

High Benches.—These are the remains of the Pliocene creeks, and usually appear as a bench deposit with one rim completely removed by erosion. (In one notable instance, near the mouth of Bonanza creek, the deposit is about one mile wide and has both rims intact.) They constitute the famous White Channel, so named by Californians, who were familiar with a similar occurrence in their own State. Together they contain several hundred million cubic yards; the hydraulic process has in several instances been most successfully applied in the exploitation of these gravel deposits.

A definition of that somewhat loose term 'overburden,' is essential. It is often used as meaning barren overlying material; more properly, it should include all material above the pay-gravel, no matter whether gravel, soil, clay, or lava, auriferous or barren. 'Overburden' from the drifting viewpoint may be 'pay-ground' if worked by hydraulicking. It has been said rather generally that the White Channel has no overburden. This is not correct, for, in several operations, where gravel was encountered from grass-roots to bedrock (no soil or muck occurring), the low value of the upper section made it an overburden of serious consideration. All the gravel could have been worked profitably had cheap methods been applicable, but, in the instances cited, there was enough overburden to kill the undertaking.

Klondike is a region of great concentration, both vertical and lateral; the pay-streaks are shallow and narrow. Though a long period has elapsed since the deposition of the White Channel, the actual time during which deposition was being accomplished, is, as compared with that necessary for the formation of the similar deposits in California, much shorter. This is well shown in the sub-angular quartz boulders and gold, the slight dissemination of gold in the top gravel, the occurrence of much rough low-grade gold, and the chaotic mixing of gravel without any general bedding. The characteristics of old rivers are small, rounded, smooth boulders and fine gold (long attrition, through geologic age, is needed to accomplish these results and to cause the occurrence of gold in comminuted particles of great purity), a dissemination of value through the whole gravel section, a deposition of the gravel in strata, and the occurrence of peneplains on the rims. A deposit of gravel in places more than 100 ft. deep, overlies the White Channel. It is of a different color and composition; it possesses low value; in most cases it will be found to be an overburden. There is no muck or soil overburden of greater depth than a few inches on the White Channel.

Character of Gravel.—The boulders are all small; during two seasons I saw none that would weigh over 250 lb. and very few weighing more than 50 lb. There is no clay, little cement, and a fortunate occurrence of fine pebbles and boulders, in helpful proportion, results in a gravel of almost ideal composition for easy excavation and rapid transportation to and through the sluices to the dump. But for its generally frozen condition, it would be ideal, when viewed merely as a problem in earthwork.

Frozen Ground.—This circumstance is a serious obstacle to high duty and adds largely to cost. Large thawing area must be provided; I estimated (after observations at various claims) about 250 sq. ft. of face for each 24-hr. miner's inch, as being needed on a shady exposure. Even where ample surface is available, it is difficult to excavate material from a thin film of thawed face rapidly enough to keep the sluice loaded to its maximum capacity.

Bedrock.—The White Channel is underlaid by a favorable schist bedrock. It is easily cleaned; cuts and tunnels for sluices can be run through it at moderate expense. There are no high rims to penetrate and as the deposits are usually parallel to the present creeks, these tunnels and cuts are short. Although they have been run in frozen rock, no particular difficulty has been encounterd; frozen rock breaks well.

Value of Gravel.—Although much mining has been done on the White Channel there is little information as to the gold product per cubic yard of the gravel mined. What there is, indicates that there has been some rich ground. A yield of over $2.50 per cu. yd. 20 ft. deep. Some worked-out ground (that which had been drifted), yielded over 80c. per cu. yd. in the same way. Virgin ground, 10 to 15 ft. deep, produced over 50c. per cu. yd. when washed. A block of ground previously drifted and said to have yielded $400,000, produced, when hydraulicked, about $4,000. Expressed in another way, 12% of all the gravel contained more than 99% of the

total gold. It has been found in several instances, that ground originally rich, though worked out by drifting, produced more gold than ground unworked, because a little too poor to drift, but thought rich for hydraulicking. This may seem paradoxical, but I explain it by the wasteful early methods leaving much gold behind, and because the upper gravel is poor. In one instance, where hydraulicking was carried on extensively, it was found that calculating the yield per square yard of bedrock uncovered, about the same return was obtained for depths varying from 10 to 60 ft. This circumstance might lead to the conclusion that the top gravel is practically barren. Mr. R. G. McConnell estimates the payable drifting ground of the White Channel at half of one per cent of the total deposit The average depth of the White Channel is probably 75 ft. Assume 20c. per cu. yd. as the present cost of hydraulicking; with an average depth of 75 ft. the gravel must yield about $5 per sq. yd. of bedrock to pay expenses. The gold is clean and amalgamates well even in the cold, dirty water of Bonanza creek

Cost of Hydraulicking.—This is influenced largely by the amount of material moved per miner's inch of water; which in turn depends upon the character of the gravel, the grade and the condition of sluices, and the amount of water used. As noted above, the gravel, when thawed, is washed rapidly. The topography is such as to permit steep sluice-grades and ample dump (many parts of the White Channel being 200 ft. above and on the immediate banks of the creeks). The amount of water has always been insufficient (about 7 sec. ft. being the maximum in any operation); this has lowered the duty and raised the cost. Even then a duty of 8 cu. yd. per miner's inch per 24 hr. has been attained on a sluice-grade of about eight per cent. On the same grade in California, where 12.5 sec. ft. were used against a bank containing many large boulders and some cement, a duty of 24 cu. yd. per miner's inch and 36 cu. yd. per miner's inch where 12% grade was used, is reported by Mr. John Hays Hammond (Ninth Annual Report State Mineralogist California). If large amounts of water, say over 25 sec. ft., are used in Klondike, fewer boulders need be handled and labor bills will be materially reduced. Expense for rock-cuts and sluice-tunnels, as with shallow alluvion elsewhere, will be high.

Dump.—There is ample dump for the White Channel gravel, but much of the ground needed is not yet worked out. Dumping ground has been costly, and worked out claims (about 500 by 400 ft. each) have changed hands for $2,000 to $5,000 per claim, where the seller had (in owning the dump ground) the key to the situation.

Modified Methods.—Inasmuch as the method of handling water in hydraulic mining in California and elsewhere, when ground is unfrozen, has, for its object, the undermining and caving of banks, it is customary, except when washing high banks in more than one bench or stope, to keep the giants on bedrock. Frozen gravel cannot be handled advantageously in this way and it will prove good practice to place the giants, under certain conditions, on top of the gravel, and make the water do ground-sluicing, before reaching the rock-cuts. I tried a method similar to this and got encouraging results; conditions were such, however, that it was not possible to do much of it. It will probably be well to use a bank-head to serrate the face into ravines and thus give large thawing area. I demonstrated this during an experimental run.

Possible Sources of Water Supply.—The Klondike district is a topographic antithesis to the region on the western slope of the Sierra Nevada. Most of the creeks radiate from the Dome as the principal drainage center. The distance to the mouth of the auriferous creeks is about 20 miles; to the point on the creeks where necessary elevation for hydraulicking would place the ditch intakes, is about six miles. Thus it will be seen that extremely limited watersheds exclude the Klondike district proper from consideration as a source of water supply. There are other sources, but they are at a distance, and can only be reached with long ditches, flumes, and inverted siphons. The quantity of water available at not too great distance and at sufficient height to give hydraulic head, after carrying it a long distance through ditches, flumes and inverted siphons, has been investigated both by the Canadian Government and the representatives of mining corporations, and more than 125 sec. ft. is said to be available in each of several streams. The volume of water that will actually be delivered at the mines, in the far north, 30 to 40 miles from points of diversion, is not yet known, no observations of sufficient period and accuracy having as yet been made even with small ditches.

Canals in Klondike.—One of the several unfavorable features of a most hostile environment are those encountered in ditch, flume and pipe installation. Good ditch-ground is rarely encountered on the saddles and slopes of the ridges where ditches must run. The principal deposits, workable by the hydraulic method, are on creeks running in a generally northern direction, and water must be ditched for considerable distance on northern exposures. The surface is covered with a growth of moss, thickest on northern exposures and in the shade of trees and brush. Beneath the moss, a porous vegetable soil (colloquially called 'muck,' and often containing layers of clear ground ice) is encountered. At a comparatively slight depth loose slide-rock or the predominating shattered schist of the region is met. All the material below the moss is frozen solid and makes difficult the maintenance of a tight ditch.

An essential feature of good flume-construction is a bedrock footing for the posts forming the bents or for the sills (where no bents are needed). In many instances (where deep muck is encountered), it is well nigh impossible to get such foundation, for any considerable excavation is likely to start thawing and make slides of such magnitude as to hinder the maintenance of a flume on correct grade (such as is essential in cold climate, where splashing results in ice formation) or at all, for any leakage running under bents on muck foundation will result in washouts. Muck thaws when exposed to running water and is easily washed away by reason of its low specific gravity. Any leakage from waterways (which is, unfortunately, most likely to occur) has a much more serious import in the far north than in temperate zones. I speak feelingly in these matters for the maintenance of a short, small ditch, carrying about 3 sec. ft., on a northern exposure, for a distance of about three miles, was a most difficult and expensive problem. Slides off the upper and lower banks, washouts under flumes, settling so as to interfere with the grade, were some of an unending train of difficulties. Although the ditch was badly built in the first instance, and some of the difficulties would have been eliminated with proper construction, there were many troubles which even well-constructed waterways will encounter in the far North.

Ditch Construction.—Many costs may be quoted and C. W. Purington ('Methods and Costs of Placer Mining in Alaska,' Bulletin 263, U. S. Geol. Sur.) covers this subject thoroughly, but it is only necessary to note that common labor costs $6 per day; skilled labor, $8 to $10 per day; lumber, $50 to $60 per M for inferior stuff of 10-in. width and $10 per M more for 12-in. width; a man and two-horse team, $20 per day; hay, $80 per ton when cheapest (all these prices at Dawson). These figures make it apparent that water-way construction, even where easy slopes and free material allow excavation by plough and scraper, is extremely costly. Maintenance is likewise very high, for an exceptional environment causes a greater expenditure for this item than almost anywhere else in the world. Each spring brings a heavy expenditure for re-grading and repairing flumes damaged by snow and ice, for repairing ditch-banks where freezing and thawing have caused slides, and for mending pipe-lines which have been subjected to a temperature of —65° F. and have consequently contracted greatly. Steel contracts about 1 in 1600 for 100° F. change of temperature. Such a range is common in Klondike where pipes have a temperature of about 40° F. when full in summer, and about 100° F. if allowed to be empty, where exposed to the sun; in winter they must be emptied to prevent freezing solid and consequent bursting, when the temperature falls to —65° F. Burying pipes, to a great degree, prevents difficulty from contraction and expansion.

Water may be had under sufficient pressure, though it will require long ditches, flumes, tunnels and long, deep siphons to conduct it over such a rough country. The season is about 135 days, counting on the thaw having progressed to such a degree as to furnish water about May 15, and continuing until about October 1. This does not mean that the mining can be carried on to advantage during all of this period. The early spring nights are so cold and superficial thawing has progressed to such a slight degree that hydraulicking cannot be done satisfactorily, and only a low duty is attained. Hydraulicking must cease about October 1. With long ditches heading at high elevations and traversing northern slopes, it is probable that the actual working season will be less than the time now counted, namely, about 120 days. Even if water be available, it is unwise to prolong operations too late; spray from the nozzles forms a coating of ice which delays the next season's operations, and the possibility of being caught by a cold snap with damage to undrained pipes, gates, flumes, ditches, etc., is a serious menace.

Opening ditches and flumes, by clearing them of accumulated ice and snow, is particularly slow and costly on northern exposures. This has not been an important consideration as yet, all ditches being comparatively short, but operations that involve the maintenance of long ditches and flumes on northern exposures must prevent ice and snow accumulation as much as possible (either by coverings or otherwise) or allow time and expense for a yearly clearing. In either case, whether by installing so as to prevent it, or by cleaning ditches each year, a large item is added to the cost of construction and maintenance. Ample water can be obtained, but only at a great expense.

As water has not yet been brought through long canals in large volume, the cost of it cannot be given. Estimates made by engineers and miners, who testified before a government commission investigating concessions at Dawson in 1903, varied from 25c. to 75c. per miner's inch per 24 hrs., as the cost of water supplied if ditches were installed. These are mere estimates; but it is certain that water will cost several times as much as with ditches similar in length and capacity to those in California.

In the illustrations given herewith, Fig. 1 shows hydraulicking on the White Channel with about 7 sec. ft. of water. The ground has been drifted, and numerous timbers are seen in the pit. The character of the boulders is well shown. The main supply pipe, 15 in. diam., appears in the left foreground, and the bedrock cut shows well. Men are engaged in cleaning up the bedrock.

Fig 2 shows hydraulicking with pumped water in the White Channel of Last Chance creek, an affluent of Hunker creek. This work costs about 40c. per cu. yd., and the ground is found to yield about 50c. per cubic yard.

Copper Production. The world's copper production as figured by Henry R. Merton & Co., in tons of 2,240 pounds, is:

	1905.	1904.	1903.
Australia	36,560	34,160	29,000
Canada	20,535	19,185	19,320
Chili	29,165	30,110	30,930
Germany	22,160	21,045	21,205
Japan	35,910	34,805	31,360
Mexico	65,185	50,945	45,315
Russia	8,700	10,700	10,320
Spain and Portugal	44,810	47,035	49,740
All other countries	32,715	30,925	29,980
	295,740	278,955	267,170
United States	*413,070	**362,740	311,627
Total	708,810	641,695	578,798

*Henry R. Merton & Co.'s estimate.
**As per U. S. Geological Survey.

Vanadium is a rare metal which has come into prominence within the last four or five years, on account of the great increase in tensile strength, elasticity, and is vanadinite, or chloro-vanadate of lead. In the pure ductility it imparts to steel when added only to the extent of about 0.2% to 0.5%. Its most important ore state it should contain 19.35% V_2O_5, but the ores actually used for the manufacture of ferro-vanadium generally only contain about 10% vanadium oxide.

Tungsten has become of renewed interest within the last five years, owing to its wide and successful application for the manufacture of self-hardening rapid-tool steels. Its chief ores are wolframite, $FeWO_4$, in which some of the iron is often partly replaced by manganese; hubernite, $MnWO_4$, and scheelite, $CaWO_4$. The ore most suitable for the production of the metal is wolframite. Although found in many places, it does not occur in large masses. In the pure state it should contain over 70% WO_3, but such ores are not plentiful, and the average grade runs between 60 to 70% tungstic acid.

Molybdenum in many respects resembles tungsten, belonging to the same group of elements, and is used for similar purposes, though not nearly so expensive, one of the reasons being that it is more difficult to prepare in the pure state, and that its ores are not plentiful. The effect it has upon steel is not finally settled, and though it is said to be from two to three times as powerful in its action as tungsten, it is not to be relied upon to the same extent, as it is more difficult to alloy with steel, because of its liability to oxidize and volatilize. The chief ores of molybdenum are molybdenite, MoS_2, and wulfenite, $PbMoO_4$, both comparatively rare minerals. In the pure state it contains 60% of the metal and 40% sulphur. According to some manufacturers, wulfenite is the best raw material for the preparation of suitable metal. It is first melted with soda ash and carbon, resulting in the formation of metallic lead and a fused mass of molybdate of soda, from which molybdic acid is separated. The latter is then reduced with carbon in crucibles much like tungsten, yielding a gray metallic powder of about 95% purity with 2% to 3% carbon, and a considerable quantity of undecomposed oxides.

Metallurgical Development on the Rand.

Contributed to the MINING AND SCIENTIFIC PRESS, and read before the South African Association of Engineers, April 11, 1906, by G. A. DENNY and H. S. DENNY.

As far back as July, 1903, one of the writers had the temerity to traverse current practice and make many alterative suggestions representing departures of a radical nature. These recommendations were substantially: (1) To substitute coarse for fine screen on batteries. (2) To discard all mechanical concentration. (3) To separate the coarse product by hydraulic devices. (4) To re-grind coarse products in tube-mills. (5) To provide secondary amalgamation tables after the tubes (6) To improve the methods of inter-handling in slime-plants. (7) To make use of the filter-press in the treatment of slime. (8) To investigate the economical possibilities of reducing the whole of the mill-pulp to a fitness suitable for filter-pressing, and thus treat one product in one operation.

The point upon which the greatest emphasis was laid was the necessity for fine grinding, and overwhelming evidence was produced to prove conclusively that the pyritic constituent of the Witwatersrand ore, after being subjected to fine grinding, yielded its gold to an ordinary cyanide solution as readily as the silicious portion of the ore. It was further stated that by the use of the tube-mill the duty of the stamps would be increased and the extraction improved.

As the result of these suggestions, the first tube-mill on the Witwatersrand was introduced at the New Goch mine, and this one was followed a little later by several others at other mines. Since that time there has been a good deal of experience gained in the use of the tube-mill, but it is a significant fact that the recommendations above specified in regard to the tube-mill, secondary amalgamation, coarse screening to get increased stamp duty and higher extraction, have been followed and generally accepted in this mining center. The further suggestion to filter-press has not been followed outside of the group of mines technically controlled by the writers, and many other departures have since been jointly advised and put into practice at the Meyer & Charlton and the New Goch mines. It is on the results of the work done at these two mines that the writers propose to base the whole of the statements to be embodied in the present contribution. The real metallurgical work began in January, 1906, and we have therefore had three months in which to go into detailed investigation.

The consumption of water at the Meyer & Charlton is now 170 gal. as against an average of 500 gal. at other mines. The actual saving is illustrated by the fact that whereas before the new plant was installed the amount of water available was only just sufficient to meet the daily requirements, there is an excess today of over 100,000 gal., equal to some 300 gal. per ton of ore crushed. The consumption in the metallurgical plant is 36.8 gal. per ton of ore crushed.

At the Meyer & Charlton plant the average cost of cyanide in March was 4.19d. per ton treated, the actual consumption of cyanide being half a pound, equal to a total of 5,376 lb. The cost of lime was 0.157d. per ton treated, the actual consumption being 0.8 lb. per ton treated, the total consumption being 8,460 lb. The total amount of solution in circulation amounted to 2,133.3 tons, which had an average strength of 0.038% KCy, and an average value of 2 dwt. gold per ton, the total cyanide contained being 1,638.05 lb., and the total gold content 213 oz., the alkalinity averaging 0.008 per cent.

The average amount of gold dissolved in the mortar boxes is 1.37 dwt. per ton of ore crushed. The effect on the plates is marked, and at the Meyer & Charlton it was such that the lower portion of the plates has been cut off, as it was found that they were doing no good as far as arresting gold was concerned, while on the other hand they were showing signs of pitting and gradual disappearance in the circulating solution. These plates, however, are 12 years old, and were thin when the circulation of solution was begun. It is believed that an electrolytic action is set up as between the mortar-boxes and the plates, the cyanide solution being the medium; hence the solution of the copper. A number of investigations on the point have been carefully carried out. It is estimated that the life of copper plates with circulating cyanide solution will be something like three years, and it may be possible by the short-circuiting of the currents set up between the boxes and the plates to reduce the solvent action. Assuming, however, that the life of the plates is only two years, and that the plates themselves are only half the size of those generally adopted, the cost per ton becomes insignificant.

The recovery by amalgamation now as compared with the old system, illustrates clearly the effect of taking the fine gold into solution, the respective figures being: Recovery by amalgamation in January, 1905, 50.124%; recovery by amalgamation in January, 1906, 45.202 per cent.

There is one aspect of amalgamation worthy of mention, and that is the danger of theft, for it is a fact that there is a big illicit trade in amalgam, and the writers are of opinion that amalgamation could be dispensed with altogether under this scheme. The point has not yet been proved, but it can easily be put to the proof, and this will be done in the near future. It would be safer to have all the gold in one place, namely, the extractor boxes.

Originally it was hoped that filter-pressing would be unnecessary. This hope was based on the assumption that a product could be discharged continuously from the last vat, which would contain not more than 50% moisture. After some years of experience the conclusion was reached that this was impossible, and at the Van Ryn mine, two years ago, an arrangement was built for returning solution from the slime-dam. After careful consideration, however, and after giving due weight to the maintenance of slime-dams, cost of pumping back solution, losses by absorption, and the danger of the dams giving way, there could be no further doubt that filter-pressing must be adopted to complete the operation. The slime-plants at the New Goch and Meyer & Charlton are now simply being used as storage-tanks; that is to say, the whole of the available gold is in solution before the slime reaches the slime-plant, and therefore it is not called upon to do anything in that direction. At the Van Ryn, where solution is not circulated, the slime-plant is showing over 93% of the total gold in solution in the first four tanks. At the Charlton, however, with the circulating solution, this gold has already been absorbed before the slime-plant is reached. The superiority of the design of this plant over the ordinary type of decantation plant, is that the inter-handling can be done simply by the regulation of a valve and at no cost; and as a storage plant, to be worked jointly with a filter-press, it has many points of advantage.

In view of the fact that the circulating solution has already been in contact with the sand before it reaches the sand-plant, the value of charges under present conditions shows a big reduction, and from an 8-dwt. screen-assay the present condition gives a return in the settlers of under 1.5 dwt., and in the treatment-tanks of 1.4 dwt., which, under old conditions, would, in the latter, have been in the neighborhood of 5 dwt. The sand-plant consists of eight vats in all, four of which are superimposed and are called the 'settlers,' the four below being called the 'treatment-tanks.' As a matter of fact, however, solution is being pumped to the settlers as well as to the treatment vats almost constantly, and by this means, instead of a treatment of four days, which would have obtained under the old system, a treatment of nine days is obtained. The sand-plant is only responsible for 10% of the total gold recovery, which when set against the cost of operating the plant and the interest on capital outlay, at once proves it to be a most expensive department. If the interest on capital outlay and the actual operating costs of this plant be allowed as a credit toward the cost of all sliming, it leaves a big margin in favor of fine grinding, and the intention of the writers on this evidence is entirely to discard the department so generally devoted today for the treatment of sand. Not only this, but the residue from the sand-plant has neither the consistency nor the low value of the filter-press product, and sufficient investigation has been done to indicate that if coarse sand be reduced to 150-mesh it can be filter-pressed just as well as ordinary slime. The average residue then, instead of being in the neighborhood of 12 gr., would be reduced to, at most, six grains per ton.

On a basis of 96 tons per day passing through the tube-mill the extra revenue is £15 15s. 7d. per day for each mill in use. The deduction generally is that fine-grinding is a necessary corollary to any metallurgical treatment of Rand ore, and the evidence points to the further extension of this principle.

Experimental data show that filter-pressing is one of the most necessary operations that has yet been introduced into local practice. The points are the great saving of water, the increased extraction, the saving of cyanide, the economy of time in treatment of slime, and the production of a better product for handling on the slime-dump. The operation is one of the very simplest, and experienced white men who have been filter-pressing for many years in Western Australia are quite satisfied that the native is just as good a filter-pressing hand as the white man. The reason why this method was not adopted earlier was due to the fear of excessive cost. Our figures not only disprove this idea, but show that filter-pressing is the most important operation in the whole range of treatment. The average residue from slime during March at the Charlton contains 0.2886 dwt. The fineness of the gold was 753.962, and the amount of acid used 4,988 lb., equal to 1.304d. per ton treated; and the amount of zinc used 3,834 lb., valued at £63 18s.

The addition of a filter-press plant to the mill settles one point that is usually subject to inaccuracy, and that is the tonnage of slime handled. The relation of extraction to tons multiplied by screen-assays has not, in the past, been so close that this point has come up for serious discussion, but in the future there is no doubt that more attention will have to be given to it.

The costs for the month of March are as follows:

	Total cost Pounds.	Cost per ton milled. Pence.	Cost per ton treated. Pence.
Tailing-elevator	279	6.23	6.23
Sand-treatment	447	9.99	14.08
Slime-treatment	362	8.08	27.82
Extractor-house	436	9.73	9.73
Total cost.....	1,523	34.03	57.86

It will be noticed from this statement that the cost of elevating the pulp is high, figuring at 6.232d. per ton milled. Apart from this cost, the actual expenditure is 27.811d. per ton milled. When it is considered that this covers the whole cost of sand-treatment and slime-treatment, including filter-pressing and the cost of dumping residue, this result must be regarded as eminently satisfactory for a new plant.

As already indicated, the sand-plant is only responsible for 10% of the gold recovered; while the slime-plant is doing nothing, and therefore is not required. The highest residue is in the sand-plant, and the costs of running it are also high. The final conclusions on actual data are (1) that the credit of the cost of re-grinding to be established by discarding the sand-plant, and, allowing for the interest on the capital outlay and the actual working costs of the sand-plant, is more than is required to cover the whole of the cost of re-grinding; (2) that the extraction on the one-product basis, where everything would be filter-pressed, shows a further improvement in favor of all-sliming; (3) that a plant on the all-sliming basis could be erected complete at somewhat less than 50% the cost of the ordinary sand and decantation slime-plants of today, to give a much higher and far more consistent recovery, and to be worked at a much lower cost. In the design of the all-sliming plant the stamp battery is left out, the principle being crushing and grinding in stages.

The grinding analyses of the products show some curious features. One in particular is that the grading of a settled sand is quite different from the grading of the charge which that sand represents when transferred from the top to the bottom tank. It is difficult to determine exactly how this change is brought about; but, as the results have been confirmed in many investigations, there can be no question that the change does take place. It may be said that work could not be carried out satisfactorily without grading analyses.

Shortly after starting the plants, the residue value, both in the slime and the sand plants, occasionally was high. In every case, it was found that high residues were due to reasonable causes, such as could easily be controlled when the operators had a full knowledge of the conditions. There is no reason why the filter-press residue should ever be higher than 6 gr. or the sand-residue be higher—given that the tube-mills are running—than 12 gr., and this quite apart from the screen-assay. Taking the case of the Meyer & Charlton, however, which in March had an average screen-assay of 10.871 dwt., the average residue in the sand was 144 gr., and in the slime 6.91 gr. The percentage of the total pulp represented by sand was 70.763, and the slime 29.050. This gives an average residue of 12.39 gr., equal to an extraction on the screen assay of 95.302%. The total gold cleaned up shows an actual extraction of 95.5%. In this plant 96% theoretical extraction should be easily and consistently realized, and allowing for 1% loss in the smelt and clean-up, etc., the actual gold in the bank should be 95 per cent.

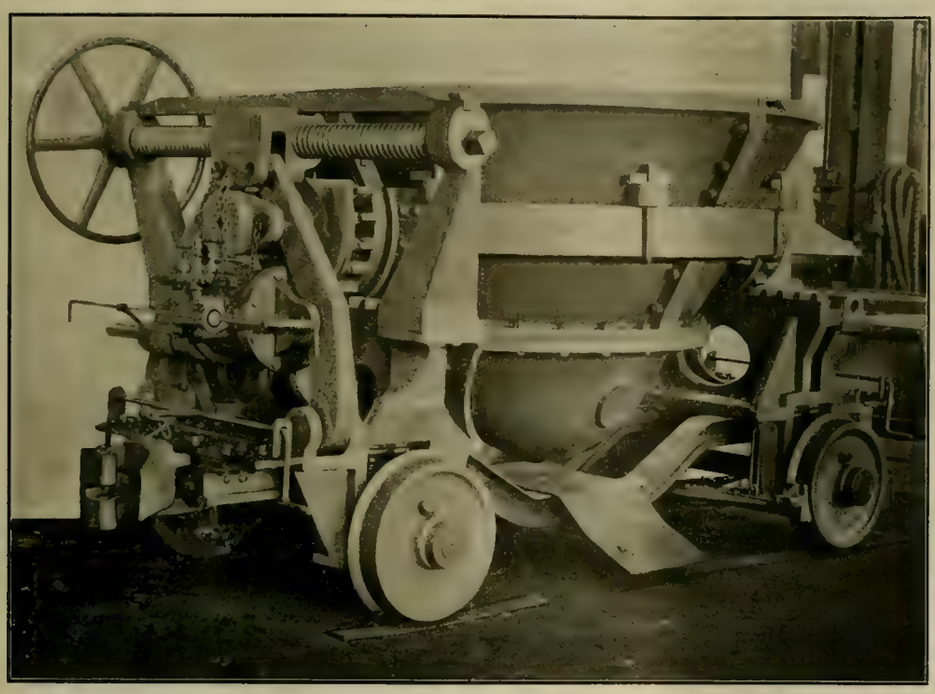
Mannesmann tubes are weldless pipes made by a peculiar process from the solid steel bar. Three and four-inch tubes, 0.25 in. thick, have been tested to 2,000 lb., while corresponding cast iron tubes will stand but 200 lb. and wrought iron but 1,000 lb. per sq. in. This great tensile strength is probably due to the fact, that, in addition to being much more worked than most metal, the fibers of the metal run spirally, as has been proved by microscopic examination. Lengths of such pipe up to 70 ft. long and 3 in. diam. have been made by this process.

The Hand-Stamp.

Written for the MINING AND SCIENTIFIC PRESS by GEORGE J. BANCROFT.

One of the difficult things about sampling a mine, particularly a large one, is the crushing of the samples. I like to take plenty of large samples, but, before I hit upon my present method of crushing, I was sometimes sorely tempted to 'skimp the job' and take small ones. So I think a device that makes less onerous the bothersome work of crushing samples will be welcomed by many engineers.

My device is particularly applicable for wet or 'gummy' samples and for those mines where no power-crusher is available. It may be described briefly as a hand stamp. Stamp and crushing plate may be made in an unlimited number of ways. An investigation of the mine 'scrap heap' will generally reveal something that will do to shoe a stamp or make a crushing plate. The accompanying illustration shows a hand-stamp made of a sawed-off mercury flask and a scantling. A good stamp can be made of a piece of four-by-four shod with strap-iron. The thicker the iron the better, but if no thick stuff is at hand, the iron may be doubled. An all-iron stamp is also a good tool and the mine blacksmith can generally manufacture one out of material on hand. The essential things about the stamp are that it should be about four feet long, have a face about four inches square and weigh from 15 to 18 lb. The crushing plate can be made from any flat piece of iron that is three feet square or larger. The bottom of an old amalgamation pan makes a fine crushing plate, but it is apt to salt the samples. Generally the best thing available is a turn-sheet. This makes a good crushing plate if it has a firm, flat foundation. A platform of new rails or of heavy timbers is useful for this purpose. At a pinch a large flat rock may be used as a crushing plate but, of course, it has the objection of being hard to clean.



A HAND-STAMP.

Recently a young engineer, by name S. A. Ionides, who was traveling with me, prepared some figures on the relative speed of crushing with a hand-stamp and with the old method of single-jack and die. The average of several tests showed that a Mexican would crush one-third of a pound by the aid of a single-jack in one minute, while, in the same time with a hand-stamp he could crush two and one-half pounds, the samples in each case being crushed to about the size of corn. The hand-stamp then is about eight times faster than the single-jack. A mortar and pestle I have found to be even slower than the single-jack and die, but I have no comparative figures.

In crushing with the hand-stamp the sample is dumped on the crushing plate and spread out with the foot. The crushing then begins, the operator moving about the plate till all is crushed. It comes natural to strike just between the feet, so the feet keep the brittle stuff from flying, to some extent, but if trouble arises from flying bits some boards may be set up around the plate. After crushing, the plate is often useful for a preliminary quartering, particularly if the sample is very large. If the plate is on a platform and so arranged that a box or other receptacle can be put under one edge, the operation of removing the crushed sample is greatly facilitated.

A New Slag Car.

The accompanying illustration shows a 10-ton slag-car, of which 15 were recently built by the Power and Mining Machinery Company, of Cudahy, Wisconsin, for the new Garfield plant of the American Smelting and Refining Company near Salt Lake City. Some idea of its size can be gained from the over-all dimensions,—15 ft. long and 6½ ft. high. Each car weighs 27,000 lb. when empty, or 47,000 lb. when filled with slag. The bowl is made in five sections, the bottom being made in one piece with four quarters forming the top. This allows of any worn or broken part being easily replaced. These sections are securely bolted together and tied to a steel supporting ring by key-bolts. The supporting ring is securely riveted to the pinion-toothed trunnions which roll on a racked track. The pinion and the rack are both made open between the teeth to prevent their being clogged by any slag which might be spilled into them. The trunnions are rolled by means of a sleeve which is operated through a lever by a 12-in. compressed-air cylinder. This cylinder is designed to operate on 60-lb. pressure and to tilt and hold the pot in any desired position. The air-valve for this cylinder is a simple four-way cock conveniently operated from the side of the car. All the levers and other operating parts are made of steel to reduce the weight of the machine without sacrificing strength. A hand-wheel and screw are also provided so that the bowl can be dumped by hand, should the air-supply fail from any cause. When tilted to the extreme position, the side of the bowl makes an angle of 50° so as readily to allow the slag-skull to slide out. The bowl in dumping is carried to the side of the car by the rolling of the trunnions, so as to dump outside of the rail. An apron in the middle of the truck prevents any drippings from falling on the track. The entire body of the car is carried on eight powerful springs placed under the front and rear supporting frames and resting on the main bearing-boxes. These bearing-boxes are fitted with phosphor-bronze bearings which are kept lubricated by removable oil-waste boxes. The two supporting frames are tied together by two 100-lb. rails securely riveted to them, and extended to carry the Tower automatic couplers. These are provided with the usual side-crank attachment for releasing the coupler. One of each pair of wheels is provided with a bronze bushing so that it can revolve on the axle when going around a curve. A large factor of safety was used in the design of all the parts of this machine because of the rough usage to which it is put. Special pains were also taken to make it as simple as possible to operate for the men usually employed for such labor. Slag-cars of this design are made in various sizes up to 15 tons in capacity, and with or without the air-cylinder.

A NEW SLAG CAR.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rock specimen from Independence, Cal., marked F. C. is mostly Garnet, accompanied by Calcite. It is somewhat unusual in containing pyrite.

The samples from Chilpancingo, Guerrero, Mexico, marked E. I. R. are as follows: No. 1, altered greenstone with calcite, and a little quartz. The bright mineral is mostly pyrite and galena; No. 2, silicious amphibolite schist; No. 3, a dense, silicified greenstone schist with pyrite; No. 4, talc schist and quartz; No. 5, quartz; No. 6, principally quartz with sulphide of zinc, iron and lead. The zinc in this sample is most abundant, the mineral being brownish crystallized and brilliant zinc-blende; No. 7 is a complex sulphide ore, consisting of intimately associated iron, lead, copper and zinc sulphides in an altered and silicified greenstone. No. 1, 6 and 7 probably also contain gold and silver.

Collapse of the Open Workings at the Kimberley Mine.

On Thursday morning the loose shale on the sides of the Kimberley open mine commenced to fall in, and throughout the day the wonderful spectacle was presented of huge quantities of loose material sliding down from many parts of the exposed workings just below the rock level and disappearing into "the biggest hole in the world." General attention was drawn to the fact that a slip had occurred about 10 o'clock, when a vast mass of shale fell from the east side of the mine, near the surface, and crashing down to meet its first obstruction nearly a thousand feet below, raised a dense cloud of dust, which hung over the mine for some considerable time. As the day advanced the extent of the slip was gradually extended, until, late in the afternoon, thousands of tons of shale were pouring down the big hole from practically its whole circumference. At noon the falling material was distinctly visible as it started on its downward career, but later in the day, so general was the area affected, that the resultant thick pall of dust obscured everything from view. Hundreds of people visited the vicinity during the day, the spectacle afforded, with the accompanying noise, being a somewhat weirdly affecting one. The moving ground disappeared from view with a sound like that of a mighty waterfall, and the well-known abandoned workings took on a new appearance before one's eye in a startling fashion.

A HAND-STAMP.

The slip is attributed to a subsidence as the result of the recent rains. Some one thousand feet from the surface the falling shale fell harmlessly upon the accumulations of previous slips and the closely packed material which forms a roof nearly a thousand feet thick above the workings of the mine below. The workers down there never heard the crash with which the additions to the mass above them descended, and were unaware that material was falling in such quantity in the open mine until they regained the surface at the change of shift.—London 'Mining Journal' from 'Diamond Fields Advertiser.'

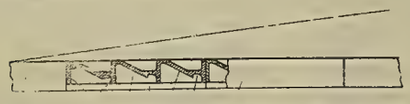
Mining and Metallurgical Patents.

Patents Issued April 24 and May 1, 1906.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

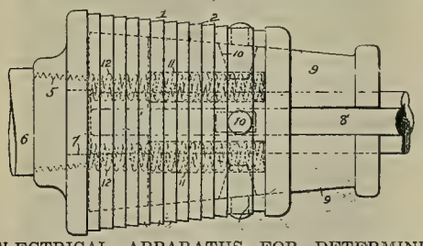
GOLD-SAVING APPARATUS, No. 818,834. I. P. Lambing, Denver, Colo.

In gold-saving apparatus, a sluice, a structure contained therein consisting of a succession of walls arranged substantially at right angles with the plane of the sluice, intermediate inclines having a steeper inclination than that of the sluice, transverse mercury-containing channels at the top of each incline and below the top of the walls, and other channels at the junction of the inclines with the bases of the walls.



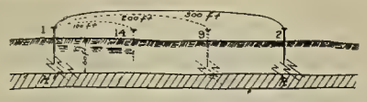
CHUCK FOR ROCK-DRILLS. No. 817,609. T. E. Adams, Cleveland, Ohio.

A drill-chuck comprising a body having a tapering interior, a series of tapering jaws in said drill-body, each jaw having a socket in its rear end, a separate spring for each jaw, said springs entering the sockets in the jaws, and a series of pins rigidly secured to the chuck-body, said pins projecting inwardly from the inner wall of the chuck-body and entering between adjacent jaws.



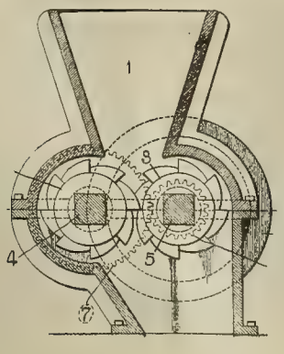
ELECTRICAL APPARATUS FOR DETERMINING THE LOCATION OF METALLIC ORES, No. 817,749. F. H. Brown, Los Angeles, Cal.

In an apparatus for locating metallic ores and similar substances in the earth, means for establishing two electrical circuits, one of which includes a variable resistance and the other is adapted to contain the portions of the earth to be tested, means for causing a divided current of electricity to pass over circuits in unequal volumes, means for indicating the difference in volumes, a contact for movably engaging with resistance to equalize volumes, and a telephone-receiver for determining when volumes are equal, receiver being in the circuit having the variable resistance and connected with and forming a part of the means for indicating the difference in volumes.



PRELIMINARY BREAKER FOR CRUSHERS AND PULVERIZERS, No. 818,328. M. F. Williams, St. Louis, Mo.

In an apparatus of the character described, the combination with a casing, the upper portion of which forms a hopper, two shafts having squared portions mounted in said casing below the hopper, cylinder-sections arranged on the squared portions of said shafts in intimate engagement with each other and provided with V-shaped teeth, the cylinder-sections of one shaft being staggered with relation to each other, whereby the paths of travel of teeth intersect each other on the respective cylinders, a pulley on one of shafts, a pinion on the other of shafts meshing with gear whereby shafts rotate at unequal speeds, and a balance-wheel on the shaft carrying the pinion.

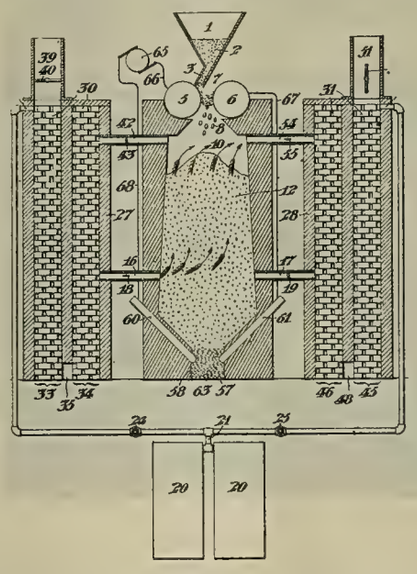


MINER'S PICK. No. 817,512. W. S. Palmer, Blairsville, Pa.

A miner's pick comprising a head provided with a longitudinal bore in the opposite ends thereof, said bore having grooves at opposite sides thereof and provided with a transverse opening 5 intersecting the terminal end of said bore, a detachable point having a reduced stem to enter said bore, and radial flanges to engage grooves, a reduced threaded shank to project into said transverse opening, and a thumb-nut mounted upon the threaded shank of the stem.

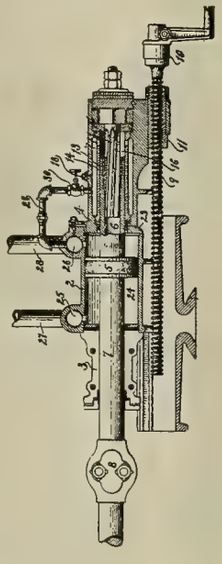
PROCESS OF MANUFACTURING IRON AND ITS ALLOYS, No. 818,918. M. Ruthenburg, Lockport, N. Y.

The continuous process of reducing ore to the metallic state, which consists in fritting comminuted particles of ore in coherent porous lumps, collecting the lumps in a confined heated atmosphere, then before lumps have fallen below a reducing temperature, subjecting them to the action of reducing media in confined heated atmosphere and reducing them without fusing them, and then increasing the temperature of lumps, until the reduced metal is melted.



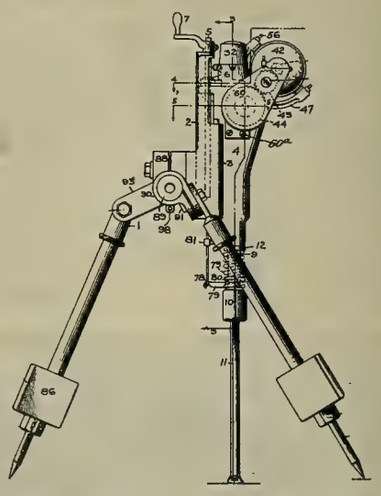
ROCK-DRILL, No. 818,681. H. Gibson, Easton, Pa.

A rock-drill piston having a tail-rod, a cylinder having an extension provided with a tail-rod chamber and having a vent-opening leading from chamber to the external atmosphere, and motive-fluid-pressure pipes for the cylinder, cylinder having a passage leading from one of pipes to the tail-rod chamber.



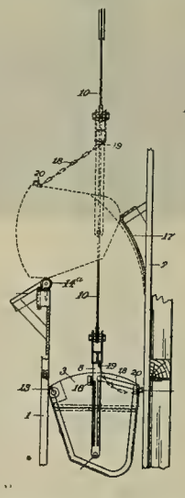
ROCK-DRILL, No. 818,015. R. Binnie, Sr., Bolivar, Pa.

In a drill, the combination of a support, a drill body or casing movably mounted thereon, a reciprocating drill-spindle mounted in casing, an actuating-shaft for spindle also mounted in the casing, a motor mounted directly on the casing on trunnions at right angles to the actuating-shaft, cushioning means between trunnions and the casing, and gearing connecting motor and drill-actuating shaft.



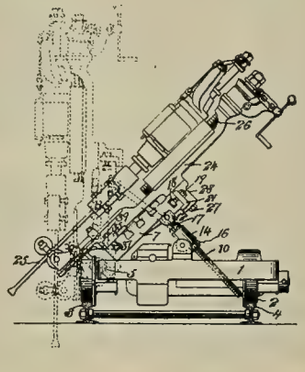
DUMPING-BUCKET, No. 818,668. J. Close, Columbus, Ohio.

A bucket-dumping device comprising a bucket, a bail pivotally secured to its sides near the bottom thereof, a shaft, vertical guideways for bucket disposed therein, means for hoisting bucket in shaft, the latter having a dumping-opening in the face thereof, means not connected with guideways on the back side of shaft opposite dumping-opening and projecting into shaft into the path of bucket to overthrow the same outwardly, and flexible means to limit its dumping movement.



CHANNELING-MACHINE, No. 818,558. W. Prellwitz, Easton, Pa.

A channeling-machine comprising a suitable support, a back plate mounted on the support, means for tilting the back plate, a carriage mounted on the upper edge of the back plate, a drill-carrying shell pivoted to the carriage and means for clamping the shell to the face of the back plate.



Special Correspondence.

JOHANNESBURG, April 3.

The whole community has been shocked beyond words by the news of the awful catastrophe that has befallen San Francisco. The deepest sympathy is felt here for the fair City of the Pacific, in this her hour of woe. Everyone hopes and believes that while the visitation may bring financial ruin to thousands, it will not break the spirit of the citizens of the great City; that they will set to work to build up the desolate places, with that determined American courage which is so well known, and so well appreciated the world over; that in the future the people of San Francisco will point to the re-built city with the same pride that the citizens of Chicago and Galveston exhibit, when they show the stranger how they faced their ruin.

Affairs in Johannesburg are moving along fairly well. The March output of 443,723 oz. establishes a record for the Transvaal and is distinctly encouraging. The war cloud in Natal is being watched with interest. The feeling is that there will be no Zulu rising, but precautionary measures are being taken. Recruiting has commenced, and last week 25 of the Rand unemployed left to join the forces in Natal. They are to receive 5s. per day. A native rising at the present time would be a terrible thing for South Africa. It would cost millions to put it down. Should it come, all the white inhabitants would stand by Natal. There is no danger of any native tribes joining the Zulus.

A commission has been appointed by the government to inquire into Chinese crime along the Rand. It is to be hoped that the labors of the commission will bring about means to stop the crime of the Chinamen, but it is a difficult problem. If every householder, especially in lonely districts, were fully armed, the Chinese would soon decide that robbing farms did not pay.

Good Friday is a legal holiday, and it is also Labor Day on the Rand. This year there was the usual demonstration of labor in Market Square, Johannesburg. The labor leaders made characteristic speeches, in which capitalists were more or less blamed for all woes that afflict the Transvaal. An eight-hour day on the mines was demanded; protection for struggling industries was recommended; unaltered opposition to Chinese labor was announced; political questions were discussed, and the working men advised to send their own men to Pretoria. The repatriation of the coolies was, of course, recommended, and the speakers held that more pressure should be brought to bear on the Kaffirs to make them work. Labor organizations on the Rand are, on the whole, rather weak. Most sensible men realize that the skilled workman on the Rand is better off than in most places in the world. If the Chinese were repatriated, they know that the majority of the mines would close down, and that hundreds of white men would be brought to the verge of starvation.

TORONTO, May 24.

Cobalt has had its first serious disaster in the form of a dynamite explosion followed by a fire on the 18th inst. In view of the crowding together of flimsy wooden structures and the lack of an adequate water-supply and fire-protection service, the destruction of the town has long been anticipated as likely to occur at any time. However, the threatened calamity was not of as serious a character as the first reports indictated, and later details, though meager, show that the fire was got under control before it became general, and that no loss of life or serious bodily injuries resulted.

Several important finds have been made recently. For some time diamond-drilling has been going on at Clear lake, a short distance west of town. Major Gordon, mining engineer, having traced a vein on the lake shore, undertook the work of prospecting the area under water and put down a drill-hole by means of a casing pipe in 60 ft. of water. Bedrock was struck under eight feet of mud and boulders, and a core from the vein was found to assay well in silver, besides containing a nugget of native silver weighing about an ounce. The rock at the bottom of the lake has been ascertained to be Huronian, which adds considerably to the value of the proposition. A shaft sunk to a depth of 25 ft. on the neighboring mainland has struck a calcite vein yielding 275 oz. per ton. These discoveries have directed attention to the locality.

The preparations for hydraulic mining on the Nipissing or Carl properties at Peterson lake are going forward rapidly. Superintendent Linney has 90 men engaged and is adding largely to his force. The boilers and engines of the hydraulic plant have been installed and work will be started by the middle of June. The depth of soil will hardly average four feet, and the superintendent hopes to strip from 150 to 200 acres in the course of the season. It is probable that some of the other operating mines will resort to the hydraulic process. The Nipissing Co. has shipped ore valued at $1,200,000 during the last 15 months, and several carloads are stored in addition.

A large nugget of native silver has been found on the Rothschild property, south of Giroux lake. It is stated to be the second largest found in the camp. The claim where it was found immediately adjoins the Little Nugget, or Wiley location, which was recently sold to American capitalists.

The process of joint-stocking the more celebrated mines and putting the shares on the market goes on rapidly. The public, who have been hit so hard by wild-cat propositions in connection with British Columbia mining, is getting a little shy of mere prospects and calcite veins, but a going concern with a good shipping record has strong temptations for those who are speculatively disposed. The experience of the shareholders in the old Hudson Bay Stonnont mine—now the Silver Queen—who received 200% dividend on the first shipment of ore, which boomed the dollar shares to $60 and upward, has given a stimulus to speculation in actually producing mines. The famous University mine has been turned over to a joint-stock company with a capital of $1,000,000, the former owners retaining a large interest. The Cobalt Contact Silver Mines, Ltd., has acquired the Green property of 40 acres adjoining the Red Rock. They are incorporated with a capital of $300,000 and the members include John C. Quinn and George Lozensky, two experienced California miners. It is proposed to divide the property into single-acre blocks and lease alternate blocks as is done at Goldfield, Tonopah, Cripple Creek and other Western camps. They are selling stock extensively in New York.

The township of Coleman, which embraces the Cobalt mining area, has been constituted a special mining division under the new Mining Act. The regulations restrict the size of a claim in a 'special,' as distinguished from an ordinary, mining division to 20 acres, which is to be the limit of claims in future.

The Ontario government has brought action in the Courts against a number of holders of mining leases in the Cobalt area to have their claims set aside on the ground that they were fraudulently obtained by false affidavits of discovery. The first of these cases is now being heard by Justice Boyd of the High Court and the trial has already occupied several days and will continue for some time longer. The parties proceeded against are Edward C. Hargreaves, Bay City, Mich.; Frank Rutherford, Niagara Falls; Chas. G. Williams, Montreal; and the White Silver Mining Co., Toronto, who hold leases covering 200 acres of mining lands. It is claimed by the government that the prospecting said to have been done in November, 1904, and occupying some four days, was impossible of accomplishment as the ground was covered with snow at the time, and that the affidavits of discovery were consequently fraudulent. There are numerous other cases of the same nature to be heard, as large areas of Coleman township have been covered by blanket claims. Should the result of these trials be to declare these claims invalid and to re-open the land for prospectors, there will be great rejoicing in Cobalt, where the people have long been looking forward to the cancellation of fraudulently obtained leases.

There is great activity in the search for valuable minerals in northern Quebec where it is now ascertained that there is a mineral tract, probably of equal richness to the new Ontario mining region, of which in fact it is simply a continuation. Prospectors swarm along the Hudson Bay slope, all the way from Lake Temiskaming on the west to the region north of Lake St. John in the east. The particular quarter to which attention is now directed is the district north of Lake Chibugamoo, stretching toward James bay. The Chibugamoo Gold & Asbestos Mining Co., the principal interests in which are represented by J. A. Jacobs and Peter McKenzie of Montreal, have a number of prospectors out in that direction. One of them has just returned bringing back gold nuggets to the value of $4,000. The company maintain strict secrecy as to the locality where these were obtained and are losing no time in securing the mining locations. Other prospectors in their employ report the finding of extensive copper deposits between the Rupert and Nottaway rivers. The Grand Trunk Pacific Railway, now under construction, will pass about a hundred miles to the south of the Chibugamoo district, and its completion will be followed by a great rush to this region. Many representatives of British and American companies are now in the country in search of mineral deposits.

MELBOURNE, April 12.

A fire in the Broken Hill Proprietary mine, has, to use an old-fashioned saying, put one or two kettles on the boil. It was discovered in mid-February. The official account was that the carelessness of some workmen in not returning to see that everything was safe after firing a charge, led to the timber on the 400-ft. level catching alight. When the men did go back after crib, the gallery was full of smoke, and so, although there was plenty of water available, the seat of the fire could not be reached. Since then the management has been fighting the outbreak with varying success, and the speculative world of Australia has watched the battle with the keenest interest. The danger lay in the fact that just to the north of the fire and directly overhead, was a forest of Oregon pine used for square sets in the old days, when it was thought that a lode of such dimensions as the Broken Hill lode could be worked only on the square-set system. If the flames got into this ground the prospect ahead seemed to be the closing down of the mine indefinitely. As it is, one fire which broke out in 1897, is still smouldering and it is doubtful if the first, 1895, fire is out. These were both at the 400-ft. level, one to the north and the other to the south of the present outbreak. The width of the lode at the point where the fire started, and north and south of it for some 1,000 or 1,500 ft., is fully 200 ft.; as millions of feet of timber are contained in the crushed ground between the 400 and 300-ft. level, the risk of a vast conflagration can be gauged. The mode of attack was to clear the mine of gases by the use of blowers, sink water-shafts from the surface north and south above the seat of the fire; to cross-cut north and south of the area affected and to drive behind it so that water could be poured onto it from a number of different points. To the dismay of all, when everyone was hopeful that the outbreak was under command, flames made their appearance at McBryde shaft 100 ft. further south, and the attack had to be begun anew on a larger scale, water-curtains being provided north and south of the region, with the object of restricting the spread of the flames. It has been characteristic of the management that they never concealed from the public or from their shareholders the seriousness of the situation, and it is to the credit of the staff that they have at last apparently got the outbreak under control, though not without the loss of a life or two.

Concurrently with this outbreak was the fire on the Broken Hill Junction mine, some distance to the north of the Proprietary. The difficulties here were the same as at the Proprietary: A vast lode, broken ground filled with timber and the risk of the flames affecting the Junction North, the North Broken Hill and the British mines adjoining. How this fire originated is a mystery. But there are considerations in both outbreaks which may be stated. In the first place the purchasing of Broken Hill shares for London on a big scale had led to a lot of overselling of scrip. The question has been publicly asked whether there was any connection between this fact and the fires in the Junction and the Proprietary. Where cupidity comes into play anything may happen and it seems a queer coincidence that in past instances of fire at the Proprietary as in the present case, they have taken place on a Saturday or Sunday. Next, there are also stories that since the advent of British control in one or two of the mines at Broken Hill there has been some weeding out of hands. If that is so, all that can be said is that it is a dangerous thing to attempt in a place like Broken Hill. Further than that, the question has been raised as to the popularity of Messrs. Bewick, Moreing & Co. with the labor demagogues of the Commonwealth. The firm is very largely interested in the Junction mine, it has been responsible for the placing of a large block of shares of the Junction North Company with London capitalists, it is understood to have bought into the British, and it is known to have purchased shares of the North Company. There is no doubt that a vulnerable spot in the armor of the firm exists if a spirit of revenge or criminal cupidity suggests and carries into effect such wickedness as the setting alight of mines. What the effect on the market was could be gauged from the extreme fluctuations that took place in share-values. The steadying influence, however, was London, which seemed to buy regardless of whether there was risk at the Proprietary or not.

The last fact has given some coloring to the rumor that the aim of the Bewick-Moreing, Lionel Robinson and Baillien combination is to gain a controlling in-

fluence in the Proprietary company, so as to dominate its policy in respect to the production of zinc. The company turns out weekly about 8,000 tons of zinc-residue from its mill and it has an accumulation of 2,500,000 tons of the same material at the surface. Its output and its dumps therefore are equal to those owned by, or pledged to, the Zinc Corporation. Therefore so long as it is an independent unit the promoters of the Zinc Corporation have an element of danger ahead in the trade they hope to establish in zinc concentrate. The Proprietary directors, too, have a knack of moving in an orbit of their own. They are mostly men of a type that hold aloof from market combinations. Hence the feeling of security entertained in respect to them by the outside public and by their staff. They also are wonderfully well-equipped financially to go into a contest, as the company has big cash reserves, and in all probability possesses a still larger inner trading reserve. They can therefore work on as great a scale as the Zinc Corporation in the production of zinc concentrate, while in addition they have their lead and silver output from the mine as a main source of revenue. Apart from that, the zinc residue does not cost them anything. The Zinc Corporation has to pay from 4s. to 6s. per ton to the mines from whom they have bought before they start work, and should spelter go back to £20 per ton that difference would be very important. If these facts are taken into consideration it can be seen how great a gain it would be if control of the Proprietary could be acquired. Of course no one can state if this is the objective being aimed at. None the less persistent rumors in circulation entitle the subject to consideration and therefore the matter is discussed.

SALT LAKE, May 25.

The management of the Silver King Mining Co. has closed a deal for the purchase of the holdings of the Woodside Mining Co., at Park City, also the properties of the Ferry estate, consisting of 15 claims, making a total of 24 patented claims. The deal was a cash transaction. The Woodside mine, in the early days of the Park City district, was one of the principal shippers of that camp, and is said to have produced $1,000,000.

The first rails were laid a few days ago on the Salt Lake end of the Western Pacific railroad, the new transcontinental line now building between this city and San Francisco. The grading is completed as far west as the Nevada State-line, excepting 15 miles between the Jordan river, near Salt Lake City, and Garfield Beach on the south end of the Great Salt Lake. It is believed that the Salt Lake & Los Angeles line, operating from Salt Lake City to Saltair Beach, will be taken over to cover this mileage. The Western Pacific is already looking out for Utah feeders and has a corps of engineers surveying a route to tap the Deep Creek mining district, on the western border of the State. The branch will go to Clifton, about 35 miles from the point of divergence. At Clifton, several mines are developing. One of them, the Gold Hill, promises to become a large copper producer and is controlled by Duncan McVichie, manager of the Bingham Consolidated Mining Co., and associates.

The Carbonate Hill mine, near Peterson, Morgan county, has become a regular shipper of lead ore to the Salt Lake market. Mathew Dougherty of Salt Lake, is manager.

It has been announced from a reliable source that the Guggenheims have recently purchased stock in the Little Bell mine at Park City. Developments in this property since January have been important, and it is now rated as one of the camp's principal producers. Ore development in this mine and also in the Daly-Judge, has come opportunely. With such mines as the Ontario, Silver King and Daly-West showing depletion of their ore reserves and further development of them at depth made impossible, for the present, by the cave which occurred in the Ontario adit, some time ago, the new strikes have restored confidence and the future of the camp looks brighter than for some time past.

The Utah Copper Co. is rapidly making preparations to supply ore to its mill, now under construction at Garfield, which plant is destined to ultimately treat 6,000 tons per day. To make room for yards capable of holding 300 railroad cars at the same time, R. C. Gemmell, the superintendent, has ordered the removal of several of the mine buildings and has also arranged for the changing of the grade of the Copper Belt railroad tracks in that vicinity. One of the steam-shovels ordered some time ago will be placed in operation within the next two weeks, stripping the orebodies. The first 3,000-ton unit of the mill will be ready for operation in the fall.

At a meeting to be held in a few days, the directors of the Honerine mine, at Stockton, will decide upon the character of future operations at that property. The mill will probably be ordered started up again. Work on the drain tunnel progresses, it being in 10,660 ft. The directors of the Lower Mammoth Mining Co. have called an assessment of five cents per share, to provide funds for further equipment and development. The Boston Consolidated of Bingham has increased its shipments of sulphide ore, the same going to the new Garfield smelter. The management of the new Garfield smelter has announced that a portion of the plant will be ready for operation in about 30 days.

DENVER, May 27.

As the spring wears on, it is evident that this summer is to be one of intense local activity. Colorado has not had anywhere near the influx of outside capital for its mining industry during the last two years that it had prior to that time. At least the proportion of outside capital to local capital is a great deal less. It may be that there is just as much outside capital invested in the State as heretofore, but with a constantly broadening field the local capital is becoming more and more in evidence. This is a healthy condition of affairs and one to be encouraged. Foreign capital is a doubtful blessing to the mining industry. Where the investors live a long way off, the temptation to make money quickly by the use of deception is naturally strong. There is not much use trying to fool the local investor who has been in the mining business some time.

The American Mining Congress is making a determined effort to protect the small outside investor and it is to be sincerely hoped they may be successful. There is no good trying to conceal the fact that the mining industry lends itself peculiarly to the purposes of those men who are more enthusiastic than intelligent, more energetic than capable, and such men lead others into unsound investments. The very idea of buried treasure is alluring and the business of extracting Nature's riches cannot be too strongly safeguarded. I am sure all mining men wish the American Mining Congress success in its praiseworthy efforts.

Denver has just passed over one of those trying passes in the road to perfect self-government which beset every effort in this line. The city is administered under a charter which was provided for in a piece of legislation called the 'Rush bill.' That this bill was originally conceived as a means to better self-government no one will deny, but in order to get it through the legislature so many amendments had to be made, so many interests satisfied, that it is a most unwieldy instrument. One of its provisions was that no franchises should be granted except by the majority vote of the "tax-paying electors." No qualification of a tax-paying elector was specified and no provision was made whereby the tax-paying electors might prepare their own franchises and offer them to the best bidder. As a result the public-utility corporation framed franchises which were ridiculously liberal to themselves and then, it is pretty generally believed, they created a large number of "tax-paying electors" from among their friends. I believe the corporation managers do not deny this, and I see no reason why they should. The law simply states that the "tax-paying electors" shall have the right to vote on the franchises. If Mr. W. G. Evans of the Tramway or Mr. Doherty of the Denver Gas & Electric has a mind to sell John Smith a piece of real estate for $1 which is worth $10 because John Smith is friendly to their interests, it does not seem inconsistent with the law to consider John Smith a "tax-paying elector." Whether Mr. Evans or Mr. Doherty can be convicted of bribery is another matter. The fact remains that the "tax-paying electors" undoubtedly voted the Denver Gas & Electric franchise and probably voted the Tramway franchise, the plurality of the former being 895 and of the latter 183. The Tramway plurality being very small, it may be eaten away by throwing out such votes as were technically invalid for some cause or another.

The spring activity manifests itself prominently in the employment bureau advertisements along Seventeenth and Larimer streets. Yesterday I walked down that way looking for a laborer or two. I saw advertisements for more than 600 men. I did not get my laborer.

The Clear Creek basin is still keeping well to the front in enterprises. A shaft-building has been erected at the Gold Retort mine, on Quartz hill, Gilpin county. E. G. Straub of Denver is general manager. The Four-Mile Gulch Gold Mining Co. has just been incorporated to work claims on Democrat mountain, east of Black Hawk.—James McMillan of the North Star mine on Yankee Hill is making arrangements to start the new mill at once. It is a fine new mill with a crushing outfit of ten stamps.—A new ore-shoot has been discovered in the old San Juan vein of the Nevadaville section of Gilpin county. Jack Hawn and Henry Mayhew are the lucky lessees and there is no man in the district that has more friends to rejoice in his good luck than Henry Mayhew, who has been hauling other people's ore for many a year.

The popular prejudice against long cross-cut tunnels among intelligent mining men is yielding to a more reasonable view in the face of repeated discoveries in the several long bores that are being driven at present. The Vidler tunnel in the Argentine district near Georgetown has struck a body of ore which is reported to be the biggest strike of the year in that district. The Lucania tunnel has struck two small veins of nearly solid sulphide ore during the last two weeks. One was galena and one copper pyrite and strange to say they dip in such a way that they must cross or join together about 35 ft. above the tunnel. They both carry good gold and silver values. The Lucania tunnel has been averaging 5 ft. 8 in. advance per day. This is very good work for a big adit, but it has been beaten several times in this State.

The San Juan country has taken on its customary spring activity and many new enterprises are starting. The long tunnel through Engineer mountain is to be undertaken by the Pittsburg Tunneling & Development Co. The Hanna mine at Capital City has just completed an elaborate mill, including Blake separators for its zinc ores. This enterprise is of especial importance because the Lake City part of the San Juan country has a great deal of zinc ore and there seems to be no reason why it should not be successfully worked by the modern methods of separation and concentration.

BUTTE, May 26.

The East Butte Mining Co. has added 115 acres of mineral ground to its holdings in the East Butte section. The purchase was made a few days ago after long dealings through agents who secured the ground for $51,000. A portion of the surface was sold to a real estate firm for $20,000 for city lots. Several copper veins are known to run through the property, and five years ago, during the height of the Heinze-Amalgamated fight, when ground was worth more for purposes of litigation than for mining, the owners of seven-eighths of the ground demanded $500,000 for their interests, and they might have been able to sell at that figure but the other eighth was owned by persons hostile to the side that wanted to buy, and would not sell at any price. It is the intention of the East Butte Co. to sink a shaft on the ground as soon as the Dutton shaft, on which the company is now working, has reached a depth of 1,200 ft. After the agents of the East Butte Co. had tied up the seven-eighths, the original owners were offered $150,000 for the mineral rights alone, but the offer came too late. The Dutton shaft is now down 400 ft., from which level a cross-cut is being driven, and levels will be run at each 200 ft. in depth. Sinking will continue at the same time. In nine of the shafts tributers are mining, who in April paid the company $10,000 in royalties, representing one-fourth of the result of their operations. The output for May will exceed that sum.

The Cable Consolidated Co. has begun systematic development of its placer properties. The company owns about 700 acres of ground. The development of the latter, while extensive, does not exceed five per cent of the whole. This development shows that the pay dirt extends to a depth of 60 ft. It is now proposed to bore a test hole in every five acres of ground. It is estimated that this work will cost $12,000 and when it is completed systematic operation of placers will be carried on. Meanwhile the company is working its quartz mine and producing 50 tons of ore per day. Within the next two or three weeks the output will be increased to 110 tons per day by the installation of new machinery now being put in place. The mine has been yielding gold steadily for a number of years. It is the purpose of the new company to work it more extensively. The formation is limestone. The company's placers are 15 miles northwest of Anaconda, beginning near the upper end of the gulch where it is crossed by the big vein of the Cable mine, and extends down the gulch and along the creek a distance of three miles. The dredging ground begins at the foot of the tailing dump of the quartz mine and continues in a series of flats and bars to the lower end of the company's property. The lay of the ground and the width of the various flats make it a dredging proposition. The Cable mine is one of the oldest gold-producers in the State and has yielded millions of dollars from workings less than 200 ft. deep. The Cable Consolidated Co. was organized by a number of Pittsburg

capitalists and they took over the Cable Lease Co. and Cable Mining Co. interests in the property.

The shaft of the Butte & London Co. has reached a depth of 375 ft., of which 125 ft. is in bedrock. The new hoisting engine is being set up. The old engine is still good for greater depth, and the new one has therefore not been rushed to completion. The company will place four new boilers, a new compressor has already been ordered, and several new buildings are being erected.

It is stated that the Pittsburg & Montana Co. will not abandon the Baggaley process of smelting, but may enlarge the plant when the mines are sufficiently developed to warrant it. The company is mining 100 tons of ore daily and shipping it to the Washoe smelter earning $6 per ton net, whereas the company lost money by operating its own smelter with the Baggaley process. The plans to reorganize the company have given way to the proposition to issue $3,000,000 in funding bonds, which, it is claimed, have already been underwritten. The company's mines will be developed 200 ft. deeper in hope that larger orebodies will be found.

The stockholders and directors of the Columbus-Butte Mining Co. are not working in harmony. The company again finds itself in deep financial waters and the directors, who reside in Columbus, have decided to permit the options on the Jennie Dell mines to go by default. Local stockholders have invited the old subscribers and outsiders to take another big block of stock so that enough money may be raised to take up the options, which will expire July 1. It is expected that the officers of the company will refuse to issue the stock. The Butte shareholders are prepared for that by sending an agent to Columbus to demand the issuance of the stock, or to apply to the court for the appointment of a receiver for the company.

The shaft on the Eagle mining claim in Walkerville district has reached a depth of 125 ft. and is being sunk at the rate of five feet a day. The new engine has a capacity for sinking 500 ft. The showing at the bottom of the shaft is said to be good.—The Butte and Mount Haggin Co. has been incorporated for the purpose of developing quartz claims near Anaconda. The incorporators and directors are Charles Bostrom, G. Eckstrom, H. Benson and H. T. Hendricks, all of Anaconda.—Butte men have organized the Butte & Arizona Copper Mining Co. to operate mines in the Huachuca mountains, in Cochise county, Arizona, 16 miles from Hereford. Men interested are J. H. Vivian, J. E. Corrette, B. H. Dunshee, J. C. Adams, L C. Evans, D. M. Watt, C. S. Shoemaker, A. P. Pohndorf and A. G. Pohndorf.

La France Co. has started pumping water from the Lexington mine and expects to have the workings drained in about four months. As one of the levels is connected with the Alice mine the latter will also have to be drained to that depth through the Lexington. The Lexington will in a few years be a copper producer as the Corra vein of the Red Metal Co. has been developed to the end line of the Lexington and below the present workings of the latter.—The Butte Copper Exploration Co. has reached a depth of 625 ft. and is sinking at the rate of four feet per day.—New orebins are being built at the Berkeley mine of the Butte & Boston. The Snohomish and Tramway mines will be worked through the Berkeley shaft. The three mines have been closed for a number of years by injunction.—The new steel head-frame at the Leonard mine of the Boston & Montana Co. is up, and the new hoisting engine is being put in position.

The Alliance Copper Co. was organized in Butte a few days ago by J. D. Slemons, A. T. Morgan, J. O. Hodgens, C. J. Kelly, Malcom Gillis, Donald Campbell, and R. M. Cobban, all Butte men. The property of this new company is situated in the East Butte section and consists of a number of city lots with mineral rights.—The Butte & Michigan Co., developing claims in Leslie gulch, several miles southeast of Butte, is putting in a hoisting plant. A shaft, now 50 ft. deep, is being sunk on the Julian claim, and will be put down 500 ft. before further exploration is undertaken.—The East Butte Extension Co. has purchased a portion of the Centerville lode claim, the remainder of which is owned by the American Consolidated Mining Co., being organized by J. A. Coram. The Extension Co. is making good progress in sinking its central shaft in East Butte district and is shipping ore.—Copper ore has been cut in the shaft being sunk on the Greenleaf claim by the Boston & Montana Co. The Greenleaf adjoins on the east the property of the Butte Copper Exploration Co.—The Butte & Bacorn Co. has its hoisting machinery in place and several days ago renewed sinking its three shafts with steam-power.

DENVER, May 29.

The coming of the new mining camps seems to be outside the operation of natural laws. The 'discovery' generally comes unexpectedly, both as to time and place—like lightning from a clear sky. If the commercial law of demand and supply applied to mining camps, a new one is due in Colorado now, for on every hand the desire for it is expressed—not that the old ones are played out, but they grow stale and fail to attract speculative money. So urgent has become the demand for a new camp, that the Denver Chamber of Commerce has decided to send out prospecting parties. The undertaking is laudable and may result in acquisitions of productive territory; it will be interesting to note the result. At first thought it would seem easier for a body, like the Chamber of Commerce, to find a whole new camp, than for the old orthodox style of burro-and-bacon prospector to find a single mine.

Following exploitations and tests made during a period of about five years, it is announced that Rio Blanca county has a large area of oil territory, producing the best grade of illuminating oil, unexcelled elsewhere in the United States. The field is situated on an anticlinal fold of shale 3,000 ft. thick, covering oil-bearing sand of great depth. Two productive wells are each 2,500 ft. deep. The crude oil is said to carry 60% illuminating oil, 20% paraffine, 19% naphtha and 1% waste.

The large amount of territory in South Park, being acquired by a syndicate of mining men, under placer laws, has caused considerable comment as to the equity of wholesale absorptions of this character. It is stated that a large area in the vicinity of Hartsel is underlaid with a thick sheet of eruptive rock, carrying gold to the extent of $3 to $4.50 per ton, that yields readily to cyanidation.

The Moyer mine at Leadville is producing 300 tons daily. The extension of the Moyer ore northeast has been cut by the Tucson shaft situated on the crest of Iron hill. The ore was encountered at a depth of 900 ft. The orebody intersected is over 50 ft. thick of the same character as the Moyer ore, that is, copper and zinc sulphides.—The mine operators of Leadville are calling for larger smelting facilities in view of the fact that the American Smelting & Refining Co.'s works are running at about full capacity and the phenomenal bodies of ore uncovered by recent development.

The Tungsten mines of Boulder county, heretofore operated mainly by lessees, are to be worked by companies with sufficient capital to equip their properties and modernize the operations. Hitherto about three fourths of the output has been made by lessees. Capitalists are now taking hold of the business and a large increase of tonnage is confidently expected.—The Tilly Butzel mine of Boulder county has been sold to the Calura Mining Co. for $25,000.

Another pay-vein has been opened through the Newhouse tunnel in the Silver Queen ground. It is claimed that with several feet of mill-dirt, there is a streak of smelting ore eight to nine inches wide valued at $50 per ton.—The Pine Shade vein, also operated through the Newhouse tunnel, has developed a two-foot streak of lead ore carrying gold and silver to the extent of $20 per ton.—The Vidler tunnel above Georgetown has cut the Flossie vein, disclosing a mineralized shoot 10 ft. wide. Part of the ore can be sent to the smelter in the crude state, and arrangements are being made by Mr. Vidler to erect a 50-ton concentrator to treat the low-grade stuff.

On May 25 Portland stock dropped 42c. per share. The mine is credited with a total of 10,000 tons output for 24 days in May. The company is about to erect a 400-ton cyanide-plant to treat the tailing from the Colorado City mill. No verified statement, to explain the slump, is given. One rumor has it that shaft No. 2 has been abandoned on account of exhaustion of the ground; another, that litigation is pending.—The Stratton's Independence dump containing about 900,000 tons, has been sampled by sinking some 50 shafts through it. The object is to determine whether the estimated value of $5 per ton is constant; the intention being to erect a cyanide-plant for the treatment of this dump.—The April pay roll for the Cripple Creek district amounted to $700,500.

Although the higher altitudes of the San Juan country are not yet open to traffic, rapid progress is being made toward repairing the damage to property by snowslides and fire.—The Green Mountain mill is repaired; Mr. Franklin Guiterman, of the American Smelting & Refining Co., states that the Silver Lake mill will be rebuilt at once. The construction of the Camp Bird plant is progressing rapidly and all along the line unusual activity is displayed in rebuilding.

Telluride will be deprived of railroad communication with Vance Junction for several weeks on account of a landslide, which carried the roadbed some 30 ft. below its normal level.—The Ridgeway mine located in Maggie Gulch, San Juan county, and which has produced a fair tonnage of high-grade ore at intervals for eight years, is now being operated by lessees, who have developed an ore-shoot over five feet wide, that samples 10 oz. gold and 400 oz. silver per ton; the base is an iron sulphide.—It is stated that the Pittsburg Tunneling & Development Co., operating the Wyoming mine on Engineer mountain, will tunnel the mountain to a point above Animas Forks, a distance of 13,000 ft. This old district bids fair to see a renewal of the mining activity it experienced a quarter of a century ago.

LONDON, May 16.

A company has been formed under the name of Conrad Stannite Mines, Ltd., with a nominal capital of £500,000 in £1 shares. The vendors received 360,000 credited as fully paid for the property, consisting of 10 mining leases of a total area of about 294 acres, situated at Mayo, county of Hardinge, New South Wales, about 16 miles from Inverell and 510 miles from Sydney. Some of the leases have been worked and developed to a depth of about 400 ft. by the former owners and the company will consequently soon reach the producing stage. For this reason the small working capital of £15,000 is deemed to be sufficient. The machinery already in place includes the King Conrad mill, which contains trommels of various sizes, two rock-breakers, rolls and jigs. To these there have been added, for concentration by water, six Wilfley tables, six Frue vanners, and a Wilfley slime-table. Before smelting, for separation of the products, a Wetherill magnetic separator with dynamo has been supplied. The smelting plant comprises a new 30-ton water-jacketed copper furnace, with a Root blower, in addition to the existing 10-ton reverberatory reduction furnace and the three-ton slag-furnace for the treatment of the tin slags. The mill and other machinery are driven by a splendid tandem engine made by Morison and Beardley, of Newcastle, and steam is raised in three multi-tubular boilers of 35-h. p. each, and is capable of dealing with about 150 tons per diem, or, say, 50,000 tons per year.

At the statutory meeting Mr. Alexander Hill, of Alexander Hill & Stewart, the managers, gave a full account of the property and how it is to be operated. In describing the mine, Mr. Hill said it is one of the simplest possible propositions that could be presented. The country rock is granite, and the vein occupies a fissure in the granite. It is not very wide, varying from 20 in. to 2 ft. 6 in., but it is continuous. As far as the works have gone, there are no faults or breaks of any kind in the vein. At the deepest level, 400 ft., it is just as strong and well mineralized as it is near the surface, and, as there are hard walls, but little timbering is required, and the extraction of the ore from the mine is one of the simplest operations that could be found anywhere. The ore itself consists of a mixture of practically four metals. There is lead carrying silver; that is in the greatest proportion. Next comes copper pyrites, then stannine, or sulphide of tin, and besides that there is iron pyrite and zinc-blende; but the metals to which they look for profits are lead, silver, copper and tin.

Mr. Hill explained the methods to be adopted for the treatment of the ore. In the first place they would reduce the tonnage that goes to the mill a little by hand-selection at surface. They are also able to pick out by hand some of the rich ore—some lumps of pure galena and stannine. These are put on one side without further crushing, and they are fit for direct shipment; the balance is sent to the mill, where it is crushed, sized and eventually treated by water concentration. Two classes of concentrates are made. First the pure silver-lead concentrate, which is separated easily. This is similar to the lumps picked out at the mouth of the shaft, both products being sent to the nearest smelter. The second concentrate consists of a mixture of copper and tin, with a little galena and lead, which they had not been able to separate in the first place. This concentrate will be smelted at the mine. In the blast furnace the tin separates from the copper, and a white metal is obtained carrying almost all of the copper, with a very small proportion of tin and a little lead. The tin that comes in this matte is not paid for—that is a loss—but practically all the copper and also the silver that happens to be in this matte, and sometimes the lead, are paid for. Every 100 tons of ore, as sent to the mill, will give, roughly, about 9½ tons of this first-class lead and silver concentrate and prill ore, 11.8 tons of the second-class concentrate, containing copper and tin and a little lead, and 78.7 tons of tailing, that is, waste in the form of quartz.

As regards the smelting, Mr. Hill said, before the second-class concentrate is put in the blast furnace

it has to be calcined. The slags, containing tin, are then re-melted in a smaller reverberatory furnace, poled with green poles, and a tin-lead bullion is obtained. All the lead that happens to remain in the second-class concentrate goes with the tin into the slag, and they got from the tin furnace a tin-lead bullion which is a marketable product. There is a certain amount of tin in the final process which is wasted; but the result is that this tin-lead bullion is a sort of solder, containing 56 per cent tin, 41 per cent lead, and a little silver. That was the method formerly adopted, but since October last, some trials had been made in this country and in Germany, in order to see whether it was necessary to smelt the tin and the copper together, and if the tin and copper could be separated before putting it into the blast furnace; and by means of running it over a magnetic separator it was found that the second-class concentrate could be separated in two products—that is to say, the tin from the copper and the copper could be smelted into the matte alone and that the tin could be treated alone, instead of running the two through the blast furnace. Mr. Hill stated that there were 175,000 tons of milling ore in sight which he estimated would yield a profit of £366,-700.

'The Financial News' in its latest contribution on Cornish mining states that in 1866 the mining market in London knew 128 working Cornish mines, one-half of which were regular dividend-payers. Up to 1871 some astonishing results were shown by the tin mines of the County, especially those situated on the junction of granite and slate. The particulars of 13 of the leading mines derived from the financial list of that time show that on an aggregate outlay of £230,605, dividends were paid amounting to £3,207,940. The same list contains other remarkable records from which may be taken: Botallack, for £91. 5. 0 per share paid, stood on the market at £275 to £300 per share; Dolcoath £128. 17. 6, price £250 to £300; East Pool £24. 5. 0, price £320 to £330; South Caradon £1. 5. 0, price £325 to £375; Wheal Seaton £58. 10. 0, price £130 to £135. According to the authority quoted these and many other examples given "seem to show even under the primitive conditions then prevailing in Cornish mining, it was a very much less speculative business than gold quartz mining is in most parts of the world." The continued boom in tin would make Cornwall a veritable Tom Tiddler's ground were it not for certain deterrent influences against which the casual promoter of meager resources and poor reputation is helpless. Amongst these influences the preference of the landlords in granting licenses to local men of standing or well-known financial groups is one of the most effective. From this point of view the County is to be congratulated on the formation of 'Wheal Vor Limited,' the shares of which are offered this week in the first instance to shareholders of Dolcoath Limited. The capital is £60,000 in 10s. shares. The total area of the 'sett' (situated in the parish of Breage, near Helston) is stated to be large and the purchase price of the licenses is 24,000 shares credited as fully paid, for which also underwriting and other services in the flotation of the Company are included. The prospectus states that the mine was formerly worked to a depth of 295 fathoms, and is said to have yielded at one period one-fifth of the entire tin produce of the world, making a profit of over half a million sterling, when the price of black tin was between £30 and £40 per ton. The average price for the last three years for black tin of similar produce has been £79. 14. 6, and for the first four months of 1906, £102. 11. 9. It is not at present the intention of the Company to re-work the mine to its full depth, but to carry out the recommendations of the late Captain Josiah Thomas—that is, unwater the mine to 144 fathoms below adit and work the unwrought portions of the lodes, which extend for a distance of 250 fm. east up to the great cross-course from Borlase's shaft (which is vertical down to the 144-fm. level, and in good condition). The occurrence of rich deposits of tin ore where the lodes are intersected by cross-courses is stated to be a prominent feature in the history of mining operations in Cornwall. The lease will be held from General Jago Trelawney on what are considered very favorable terms, and based on a surface rent of £100 per annum, merging in a royalty. The directors are: Frank Harvey, Hayle; James M. Holman, Camborne; Gilbert B. Pearce, Hayle; and Oliver Wethered, London; they are directors of Dolcoath, and the manager also of that mine, R. A. Thomas, is the consulting engineer. Mr. Richard Pearce of Denver is one of the largest subscribers to the undertaking. The operation of unwatering and exploring old and extensive workings such as exist in Wheal Vor will be watched with interest by mining men not only in Cornwall but elsewhere.

MINING SUMMARY

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—Eastern capitalists have recently been in Benson investigating its smelter, and it is possible that one of the visiting party will take the smelter over and operate it. Don Merrill, in charge of affairs of the Southwestern Smelting and Refining Co., in Benson, says that the smelter will probably be started within six months. The plant is in first-class condition.—A good quality of coal has been discovered in Deerfield mining district. W. P. Blake, who has made an examination of the discovery, says the coal is of good quality and cokes well. There is a solid three-foot vein, which is being mined for the Chittenden reduction plant ten miles from the mine to which a wagon road is being made. The Gila River railroad will pass within eight miles of the new coal camp.

Phoenix, May 24.

GRAHAM COUNTY.

(Special Correspondence).—I. H. Knapp, who has been in charge of the timbering work in the West Yankee mine, at Morenci, for a number of years, has resigned to take charge of the San Juan group in the valley ten miles below Clifton. The San Juan Co. has been re-organized and new capital secured for development. A new mill is being erected at the property—A 500-ton smelter is to be built at Price's Station, on the Phoenix & Eastern railroad, ten miles east of Florence, at the junction of the Gila and San Pedro rivers. J. H. McCabe, of Phoenix, is at the head of the enterprise, and has associates in Los Angeles, New York and Boston.

Morenci, May 26.

The Shannon Copper Co., near Clifton, is running two furnaces and producing 1,500,000 lb. of copper monthly. In April its output was 1,312,000 lb., within 46,000 lb. of the largest previous month's production.

MOHAVE COUNTY.

(Special Correspondence).—The Arizona Birmingham Gold Mining Co., lessee of a portion of the Chloride Gold Mining Co.'s property, at Chloride, has cut a blind lead in the cross cut being driven to cut the Lucky Boy vein. The ore runs $60 per ton.

Kingman, May 26.

PINAL COUNTY.

(Special Correspondence).—W. M. Williams has gone to his mine, 10 miles west of Kelvin. This mine was located many years ago as a silver mine and was then known as the Ray mine. It carried also copper, but owing to the drop in silver was abandoned and remained idle until Mr. Williams re-located it.

Phoenix, May 27.

YAVAPAI COUNTY.

(Special Correspondence).—Two companies have been organized at Phoenix to dredge for placer gold on the Hassayampa river in this county. The two companies combined have filed on, and bought up, lands aggregating about 1,500 acres. They will prospect with boring machines.

Phoenix, May 27.

(Special Correspondence).—A large body of gold ore has been opened upon the Rainbow group belonging to the Baltimore and Arizona Copper Co. in Turkey Creek district. The deposit in a north-south direction measures 1000 ft. with an average width of 300 ft. The ore is sulphide carrying from 2½ to 5% copper, 20% iron, with gold and silver. The deepest work on the ground is a 75 ft. shaft, upon which the company will place a hoist. A compressor and machine-drills will also be installed.—It is announced that the Coronado mine at Martinez will resume operations, after a long shut-down. The property is well developed.

Prescott, May 24.

At Oro Blanco some important developments are reported. The Arizona Consolidated Mining Co. is sinking on the Oro Blanco mine. The shaft is down 250 ft. and is in a 12 ft. vein of gold ore.—At a depth of 450 ft. a vein of rich ore has been struck in the Sorrel Top. O. C. Foltz is opening a copper prospect on which he has sunk 250 feet.

CALIFORNIA.

BUTTE COUNTY.

The Bloomer Hill quartz mine, situated in the Berry Creek mining district, is to be re-opened. A. B. Chambers, the owner, has bonded the mine to San Francisco capitalists. A number of men have been at work putting the mill in shape.

EL DORADO COUNTY.

W. F. Almy has two disintegrating mills on his properties at Smith Flat, the Alcemento and Alceviro mines. The mill of the former has been in operation about two months, while on the latter a new mill is in process of construction and is almost ready for operation.—Well-boring drills are working on the Roundout mine, recently bonded by I. H. Bingham, and on the property recently held by Plummer and Swansborough. The first drill on the latter property reached a depth of 100 ft. a few days ago.—The Union mine, four miles south of El Dorado, is running, employing thirty men. Twenty stamps have been dropping at this mine during the past month. D. Humbert, who is now in possession of the property, is managing owner.

MODOC COUNTY.

(Special Correspondence.)—The Hogue mining district, near Fort Bidwell, is now being thoroughly prospected by men from all parts of the country, who are following up the receding snow line on the mineralized belts, and are finding rich float. Many new locations are being made. The snow on the main divide was going fast until checked the past week by eight inches of snow.—During the last few months the people bonding the Wade Plummer claim have sunk a prospect shaft 50 ft. deep near the contact, and cut some good ore. The work was made expensive on account of the deep snow and has been suspended.—Several long tunnels were planned and partly run on the lower part of the Pine creek side three miles west of Wade Plummer, last winter, but the work was not finished, as is often the case with this kind of development, and no results were obtained.—The Mopin Sunset has established a camp just below the snow line and is beginning to sink and take out ore, which on the surface is 50% free. The vein outcrop is large. Some good ore is being obtained.—The Kafader, a small rich vein of crystallized quartz in porphyry, prospected to a depth of 12 ft. and will be developed by a tunnel run to tap the vein 100 ft. below the present outcrop. Several men are working on the extension of this vein.—Work is being done on the Williams & Turner location where they have found tellurides, partially weathered and showing gold.—The people owning the Dismal Swamp claims on the Oregon side are establishing a camp to do prospecting and development.—The Mine Venture Syndicate is doing preliminary prospecting on their large tract of patented ground with a view to leasing it in small tracts, as some high-grade ore has been found in the dikes on the surface near the Wade & Plummer ground.—This camp will probably be developed and worked largely by the leasing system for the present, and later be taken up by companies. The conditions are favorable for this method of development and operation.—The county has finished a survey for a wagon road on a six per cent grade from Fort Bidwell up the Main creek to the North Fork, a total distance of seven miles, the terminal to be where most of the men are located and within a few miles of all the more important prospects.—The most interesting find during the last month is some hard black float carrying a large amount of silver and some gold.

Fort Bidwell, May 22.

NEVADA COUNTY.

Work has been started on the new tunnel at the Gaston mine, which it is estimated will require from two and a half to three years to complete. The tunnel starts from Poorman creek and will strike the ledge at a depth of 2,000 ft. in a length of 4,000 ft. The contract has been let to Victor Redmayne who is working three shifts of three men each. A compressor and power drills will be put in. Meanwhile work in other parts of the property will continue as usual. A force of 100 men is now employed at the Gaston mine.

PLACER COUNTY.

The Goldfield-Tokop Mining and Milling Co. has bonded the Black Hawk mine, also known as the Pedlar mine, in Humbug district near Damascus. The mine is an extension of the Pioneer mine. R. E. Whitcomb, secretary of the Goldfield-Tokop Co. has been two weeks getting things in order for work. The company has leased the ten-stamp mill of the Southern Cross mine close by and is building a tramway to the mill. About 900 ft. of tunnel have been run by the original owners.

SHASTA COUNTY.

A number of Greek laborers working at Quartz Hill near Redding, have formed a company and now have control of the transportation of ore, having several teaming outfits. The ore from Quartz Hill is hauled by teams to Keswick and loaded on cars for shipment to the Mammoth smelter at Kennett. Sixty tons are shipped daily.

SAN BENITO COUNTY.

The New Idria quicksilver mines are about 45 miles west of Coalinga, with which place they have recently been connected by good wagon road. Fuel oil from the Coalinga field is to be used at these mines. The present production is said to be 125 flasks per month. Foundations have recently been laid for a new reduction furnace. Of the numerous quicksilver prospects in that section, one is being opened by the Barton brothers of Hanford. It is situated about one mile up the San Benito canyon from the road that leads to Hollister. They employ two miners and expect to operate extensively soon. A good water-power is available in the canyon. When cheap fuel is available, on the completion of the contemplated pipe-line, many mines now idle in this district will be worked.

TUOLUMNE COUNTY.

At a prospect shaft near the Grizzly mine, a mile from Carters, Fred Nicholls, a miner, was the victim of a most unusual accident a few days since. He was removing the lid from a box of detonators, when the cars exploded in his hands, seriously, if not fatally injuring him. It is supposed in twisting the lid of the tin he gripped the body of the box so tightly as to cause the fulminate to explode.

(Special Correspondence).—Another boiler and a large pump will be installed at the Louisiana mine, near Tuolumne, it being impossible to make satisfactory progress in unwatering the property with the present equipment.—The Pyrenees Gold Mining Co. has commenced work at the Patterson mine, near Tuttletown. A new track is being laid in the south drift, which is 300 ft. long and said to expose good orebodies. The buildings have been repaired and a blacksmith shop is to be erected.—Rich ore is being extracted from the Maddox mine at Confidence and shipped to Selby. Assays run over $100 per ton. The fissure is five feet wide. The rich ore is on the hanging-wall side and is two feet wide. No free gold is found. On the footwall the vein is one foot wide and carries free gold. The mine was bonded by Jos. Maddox, Sr., to Jos. Maddox, Jr., and W. H. McPherson about a year ago, when only a prospect. A cross-cut 200 ft. long has been driven to the vein and drifting both ways is in progress—San Francisco parties have examined the Buchanan mine, 12 miles south of Sonora, on the divide overlooking the main Tuolumne river, and it is reported that it will be re-opened. The mine has several veins, the principal one running east-west. It is opened to a depth of 700 ft. by shafts, but can be cut by a tunnel driven from the river, 2,000 ft. below the apex.

Tuolumne, May 29.

COLORADO.

CLEAR CREEK COUNTY.

Arrangements are being made to resume work on the Gold Fissure group, owned by Massachusetts and Rhode Island people. George A. Bristol, treasurer of the company, says ample funds to work the property are available. The entire group of six claims is to be exploited. This work will include the driving of a cross-cut from the shaft to the large deposit of ore uncovered recently in the old workings on the Gold Fissure vein. The comparatively small area stoped has yielded a net sum approximating $90,000.

GUNNISON COUNTY.

Archie McLeod of the Jim Blaine mine at Gothic reports five to ten feet of snow still in that neighborhood.—The Anthracite mine of the Pueblo Fuel Co., at Crested Butte, has started up after a shut-down of two months. The breaker now has a capacity of 100 tons per day and employs 25 men.—M. A. Pennington and Dan Dwyer have gone to their mines on Ruby peaks, prepared to do extensive development work this summer. W. Runnoe and W. McGlothlen took their outfit up on burros from the Buttes. If things are favorable this company will put in machinery and employ a large force this season.—The Gold Links has started up on the tunnel now in 1,700 ft. and A. E. Reynolds intends to go as much further. J. F. Pearson is superintendent and estimates that the Sacramento vein will be cut inside of four months

OURAY COUNTY.

Work at the new Camp Bird mill is progressing. The frame is under way and the hauling of machinery has been commenced. At what time the mine will be again in operation it is, as yet, impossible to say.—Ore is being brought down daily in large quantities from the Revenue. Nearly all the men laid off the past weeks have been replaced.—Work, which has been delayed on the property of the Ouray City Mining Co., will now be pushed.—It is said that nearly all the men who were at work at the Camp Bird mine and mill at the time of the mill's destruction by snowslide, will be given the positions they formerly held, upon the mill's completion.—At Telluride the completion of the Meldrum tunnel to the principal veins crossing its alignment is attracting much attention. A compressor and machine-drills are being considered. The tunnel is still being done by hand work and progress is slow. The Columbia-Menona vein is still 1,400 ft. ahead of the face, after which comes the Argentine, Black Bear, Tomboy and Japan-Flora, and all of these veins, and others, could be worked through this tunnel. On the Red Mountain side, several tunnels started have for their objective point this same territory, but the distance to the veins is greater on that side.

SAN MIGUEL COUNTY.

George R. Pickett, discoverer and manager of the Carbonero, is preparing to re-open the mine. It has been closed two months owing to running cut of supplies. The Carbonero produces shipping ore which is treated at the Salida smelter. Frank L. Ross, H. H. Stevens, Wm. Strieby, John R. and George B. Pickett are the owners.—A car of high-grade ore was shipped to Durango last week by the Pandora Mining & Development Co. This was an experimental shipment to determine whether shipping direct, or milling and concentration is the best practice.

TELLER COUNTY.

The work of filling the big stope on the Emerson vein of Stratton's Independence mine on Battle mountain is progressing, and it is calculated by the management that another week will see it completed. The stope is 185 ft. deep, one of the largest in the camp. It was worked so near to grass-roots from the 200-ft. level that the ground began to cave toward the south end of the stope, and there was danger of the precipitation to the bottom of the trains of the Midland Terminal railroad, whose main line was operated across the stope. For several months the railroad company has been compelled to abandon its main line and run trains, including switching crews, around by Goldfield. The railroad company has joined with the Independence people in the task of filling the hole. Several lessees are still working in that portion of the mine, but all the ore has been taken from the big stope.—It is reported that the Portland Gold Mining Co., at Cripple Creek, will build and have in operation before October 1 a 400-ton cyanide plant in addition to its mill at Colorado City. The addition will cost $75,000 and will be built to treat tailing from the chlorination mill. There are about 400,000 tons of low-grade tailing on the mill-dump which it believes it will be able to treat profitably by the cyanide process.—The fifteenth level of the Findley mine is unwatered for the first time since August, 1903, and men are breaking ore on that level. This vein was opened for 500 ft. and when the mine was closed in the strike days, 170 ft. remained to be developed at the south end. The ore-shoot is 800 ft. long—one of the largest in the camp. The grade of the ore is good, averaging nearly two ounces. By the time the Findley begins shipping in October, when the company's new mill at Colorado City will be in operation, its output will be sufficient to keep the mill running for a year without further development. No ore is being hoisted at the present time except that necessary to facilitate development. The Stratton Estate mines are among the large shippers at present; lessees on this property are doing well. Among the best shippers of the estate are the Abe Lincoln, eight cars per week; Orpha May, seven cars; American Eagles, seven cars; Deerhorn, four cars; Specimen, five cars, and the Lucky Gus, three cars. This does not represent the entire output, as numerous small lessees are working on the 250 blocks of the estate and many of them are getting out regular shipments of ore. Between 4,000 and 5,000 tons of ore are being shipped every month from the Stratton properties.

IDAHO.

ADA COUNTY.

The Old Ironsides mill in Black Hornet district, 10 miles from Boise, was destroyed by fire last week. The plant cost $28,000 several years ago. The property belonged to the Victory Mining Co. and was under lease, with option to purchase, to H. Adams of Boise. A force has been employed most of the winter, taking out ore. C. Nelson is in charge and expected to start up the mill in a few days, on ore mined during the winter.

BLAINE COUNTY.

Swanson's Independence group of eight claims, on the divide between the East Fork of Wood river and Elkhorn gulch, was sold last week for $60,000 to H. J. Allen, for himself and New York capitalists.—C. B. Dunton of Portland, Me., president of the Carbonate Hill Mining Co. is at Galena making arrangements to resume operations at that property.—J. A. Orr of Port Jarvis, N. J., president, and F. C. Kaye of New York, treasurer of the Lipman Mines & Tunnel Co., are at Hailey looking into the company's affairs

ELMORE COUNTY.

The Minerva mill, at Atlanta, has been running on high-grade ore. The larger portion of the gold was not saved on the plates. The tailing was banked, to treat in a cyanide plant recently completed.

LATAH COUNTY.

The directors of the Blue Grouse Mining Co. have decided to develop the property. The Blue Grouse is nine miles from Wallace and has been idle for six years. It is a lead-silver property and has three adits. One is in 137 ft., another in 778 ft. and the lower adit on the creek-level has just been started. It is the intention to drive this adit on the lode, gaining a depth of 1,500 ft. The adit now shows ore carrying eight per cent lead.

LEMHI COUNTY.

The Yellow Jacket mine, after being shut down for 10 years, will be started up July 1. The mine is equipped with a 60-stamp mill with water-power, tramway and sawmill. A large amount of ore is developed. It is said the mine was shut down as a result of failure of the owner.—The Queen and Crescent Mining Co., operating the Queen of the Hills mine near Lemhi, in a cross-cut tunnel, at 1,038 ft., broke into fine ore, and the miners have driven 10 ft. into the vein, without reaching the farther wall. The breast is 405 ft. from the surface.

SHOSHONE COUNTY.

The labor problem is still one of importance to mining companies in Coeur d'Alene district. At the Morning mine 60 machine men are wanted, but are not available. New miners, machine men, muckers, timbermen and millmen are being put to work every day, and the supply does not meet the demand. Miners throughout the district are paid $3.50 per day; machine men the same. Muckers in the mines directly contiguous to Wallace receive $3.50 per day, but in those about Wardner and Kellogg, $3 is paid, consequently there is more demand for muckers at Wardner than at Wallace. Experienced timbermen are always in demand, and are paid $4 per day. Millmen, in the concentrator plants, are in demand at $3.50 per day. On the south side of Coeur d'Alene district, of which Wallace is the center, 3,500 men are employed by the mining companies. The employees on the north side would bring the total to over 4,000. These men receive an average of $3.50 per day. The Federal Mining & Smelting Co. has on its pay roll 1,300 men in its mines and mills. The Morning mine, of the Federal Co., is a hard mine to keep supplied with men. Every day men are leaving the mine, and a man out of work hesitates before accepting a job in the Morning, owing to the fact that the mine is extremely wet and cold, especially at this time of year, otherwise, the Morning is all right, say the miners. Conditions generally under which men work in this district are said to be above the average in mining regions. The bunkhouses are, as a rule, kept in good order, good dry rooms are provided at every mine for changing clothes, and the board is good. Most of the mines, too, are dry.

Following is the official report of the output and net profits of the principal mines of the Coeur d'Alene district, handed in by the several companies to the county assessor in compliance with the State law:

Company.	Tons of Ore or Concentrate	Gross Value	Net Profit
Bunker Hill	342,414	$4,586,112.84	$1,957,477
Federal (4 mines)	904,004	5,962,385.59	1,565,218
Hercules*	11,422	943,306.96	375,349
Hecla	97,366	871,449.38	363,125
Snow Storm*	65,500	834,825.03	245,267
Frisco	1,125	64,457.11	.....
Coeur d'Alene Development Co.	75	3,204.49	.....
Gold Hunter	41,634	143,207.59	.....
Total	1,463,540	$13,408,948.99	$4,506,436

* Crude ore only.

As indicated above the complete returns are not yet made. These returns are from those companies making a net profit, but takes no account of those operating and making a substantial output, but without profit. Among these are the Pittsburg (California), Stewart, Success (Granite), Rex (Sixteen-to-One), Tamarack, Monitor, Idaho-Montana Summit (Black Horse), and Monarch, all shipping more or less ore and possi-

bly some others. The jiggers on Canyon creek, the South Fork and Milo creek also shipped approximately 1,000 tons of concentrate worth about $50,000.

NEZ PERCE COUNTY.

The Crackerjack mill is to start on May 15. Recent development at the mine has opened up a fine body of ore. A sufficient water supply is reported available. The Crackerjack is equipped with a 10-stamp mill, and 30 tons of ore will be handled daily. The electric plant which provides the power, cost $18,000.

MICHIGAN.

HOUGHTON COUNTY.

Owing to the settling of the ground the Atlantic mine has been compelled to suspend production entirely and operations at the mill have been discontinued. The subsidence of the ground in this mine has been in progress for several years, but during the last two years it has been more pronounced than formerly. Numerous expedients have been adopted to keep the shafts in commission and prevent a general shutdown, but the hanging and foot-walls of the lode in the shafts have come together to such an extent that the skips cannot be operated. It is uncertain when the Atlantic will be able to resume. A short time ago the Atlantic closed its B shaft to permit retimbering. This work is still in progress, and it will be at least six weeks before it is finished. More recently shaft D went out of service. There has been a change in the system of mining in the Atlantic during the past two years. The new method is to drive as rapidly as possible to the extreme limit of the productive territory, both in the shafts and drifts, in order that extraction might be started at these points, and then permitting the walls to come together as the subsidence of the ground progressed.—J. H. Jasberg and Charles J. Tolonen have secured an option on 500 acres of land, four miles west of Hancock, upon which a copper showing has been exposed. Three pits have been sunk in the vein, each to a depth of 10 ft. and rock resembling amygdaloid and containing copper has been exposed. A diamond drill may be employed to determine if the formation is a lode in place. At the Arcadian a four-foot veir of epidote carrying copper, lying 35 ft. east of the vein on which development is in progress, was encountered a few days ago. The new lode was found in a cross-cut being driven eastward to cut an amygdaloid belt that is known to parallel the main vein at a distance of 100 ft.—There is an improvement in No. 2 shaft of the Mohawk mine. After passing through many levels that contain barely enough copper to pay expenses, the shaft is now in pay rock.—At the Osceola Consolidated operations are confined to the two most southerly shafts. No. 6 is down to the 41st level and work is under way in the drifts from the 30th to the bottom. There are 40 drills in operation and rock shipments average 1,050 tons daily. A new model of skip has been put in use by the Osceola Consolidated, which is expected to eliminate the trouble, particularly in No. 1 shaft of the North Kearsarge branch, resulting from skips jumping the track. Preparations for this installation at No. 1 shaft have been in progress for a long time. The new skip is a radical change from the model formerly in use. The axle and hub, which were underneath the skip lifted the body of the skip from the track over half the diameter of the wheel. These are abolished and the wheels revolve on hubs projecting from lugs riveted to the side of the body of the skip, which permit the skip to ride down close to the track.

MONTANA.

FERGUS COUNTY.

E. W. King of Bozeman, one of the chief owners of the Barnes-King mine at Kendall, says the mine is in good shape and paying dividends at the rate of $12,000 per month. In three years the mine has paid $550,000 in dividends. Mr. King is also interested in the Alder Gulch Mining Co., owning mines in Choteau county, Mont. These mines are operating a 100-ton cyaniding plant.

GRANITE COUNTY.

The sale of the Hawkeye group in the vicinity of Phillipsburg, to J. D. Haines of Butte, and the bonding of the Mountain Ram group to Butte and Colorado parties are reported. According to stipulations, a mill and cyanide plant are to be built on the latter property before the close of the year. There is also much activity near Hasmark, where lessees are shipping and every available team is kept busy hauling ore.—T. E. Mitchell and John Mullen, who have a lease on the Brooklyn and Gem mines at Hasmark, shipped two cars of ore last week from the Gem. They have been at work only a short time. Their first shipment amounted to 50 tons. Henry Steber and Fred Kelly are leasing at the Peter Coyle property just below Hasmark. They have a two-foot vein of solid galena that assays well.—Redman and Jarvi last week shipped a car of ore from the Moroney tunnel.

LEWIS AND CLARK COUNTY.

The threatened shutdown of the East Helena smelter has been averted, the men employed in the sampler, who went out some days ago, returning to work pending a settlement with the company. The men have been working 10 hours in the sampler, and quit because a request for shorter hours at the same rate of pay was not granted by F. M. Smith, manager. During last week all of the furnaces at the smelter, except one, were blown out and arrangements were made to ship the ores that were accumulating to Salt Lake and Denver.

MADISON COUNTY.

C. B. Ward, who has been cleaning up around the old Watseka mill at Rochester, says that he will make money out of the deal. He has cleaned up and sacked eight tons of concentrate, dust and ashes obtained by sweeping the mill and burning old sacks, that will run close to $60 per ton.

SILVER BOW COUNTY.

The Washoe smelter of the Amalgamated Copper Co. at Butte during the past year has brought the capacity to 9,000 tons per day, and B. B. Thayer announced several days ago that this would be increased 500 tons.

NEVADA.

CHURCHILL COUNTY.

(Special Correspondence).—On Thursday a miner, on Main street, exhibited some specimens of free gold, and stated that he had secured the samples from his property five miles south of this camp. The news spread through the town, and all made haste to go to the scene in the hope of locating something. The locators of this new strike have named their camp Bronx. It is at Indian Springs, four and one-half miles southerly from Manhattan. On three claims, the Empire No. 3, Empire No. 4 and Empire No. 5, good ore is reported. This part of the district is known as the granite belt, and huge porphyry dikes cut through the granite. These dikes are mineralized at various places. The veins uncovered range from 4 to 16 feet in width.

Manhattan, May 27.

DOUGLAS COUNTY.

(Special Correspondence).—At Buckskin, the new camp near Mason Valley, the citizens recently held a mass meeting to take action looking toward the prevention of destruction of claim monuments, and the ante-dating of certificates of location by claim jumpers. Active prospecting is in progress and encouraging results reported. Near Buckskin a newer camp is striving for metropolitan honors with the older camp. This new place is called Mountain View. It consists of a large and airy townsite. The only mining in progress in the new city is the sinking of a well in hope of finding water, but with the usual luck in such cases, gold-bearing gravel is reported at a depth of 50 ft. There are veins in the adjacent hills and some of these are said to prospect. A survey recently made has determined that Buckskin townsite is in Douglas county and not in Lyon county as previously supposed. The mining and agricultural interests have combined in the effort to secure a railroad through Mason Valley. On the Redtop claim three shifts are now working and other claims are being prospected by their owners.

Buckskin, May 28.

LANDER COUNTY.

F. Pedroncini, J. Zonino and W. Suichetti, who have been operating in Crow canyon, three miles south of Austin, have uncovered a three and one-half foot vein of silver-gold ore. At a depth of 63 ft, the water level was reached and the chloride ore gave place to sulphides. Here the ledge, with solid walls, contains a 14 in. streak that assays $1,000 per ton silver, and $148 gold. The three Italians have been operating the property alone, but they have made enough from two small shipments to work it upon a big scale.

LINCOLN COUNTY.

(Special Correspondence.)—Johnnie, both town and district, is developing rapidly. The streets are being graded. The new automobile road to Station No. 73, distant 12 miles, is completed, and mail to this place will come via Las Vegas and the Clark railroad as soon as arrangements can be made to deliver mail to the auto line, now running between this place and the end of the road. Switches, tanks, telegraph office, and all necessary belongings to a railroad station are being provided. The steel gang are away toward Bullfrog laying rails as rapidly as possible, hoping to beat the Santa Fe. Good finds are reported from all sides. Mines are being bonded, sales made, and lessees are sacking ore for shipment. Some New York parties left here this week to make final arrangements to put in a mill and cyanide plant to work a gold proposition with a large body of ore in sight, and work is to begin at once. Lack of water is the greatest drawback to this locality. It can be had by piping from the Spring Mountain range, five to ten miles east of here. Timber can be had from there also, but gasoline engines will be the chief source of power throughout this desert country for some time and smelting with crude oil may come in time.

Johnnie, May 24.

(Special Correspondence).—The Searchlight Northern Railroad is rushing work and the hardest part of the entire road is now graded. This part, which is near Manvel, was practically all rock work. After the first four miles the natural road bed will be followed and work will progress rapidly. The depot site for the terminus is on the Cyrus Noble ground.—A new company, called the Searchlight Southwestern, has been launched. The ground of this company is situated southwest of the Searchlight Mining & Milling Co. and is considered a promising prospect.—As a result of the recent visit of the president of the Santa Fe and Saturn Mining Co. these properties will undergo a general change. A larger pumping plant will be installed in the Santa Fe, and on the Saturn the 100 ft. double-compartment shaft will be sunk to 1000 ft.—After sinking for some distance in barren matter on the Fraction shaft of the Duplex Co., the shaft is again in ore, of better grade than that encountered the first 100 ft. though this 100 ft. netted the company $30,000.—Several contracts have been let on the Nevada Searchlight, work is progressing, and the showing is improving with depth.

From Dupont and Newberry districts excellent reports are coming. Both of these districts lie in a belt twelve miles east of Searchlight and the work of development on the properties there is meeting with encouraging results. Specimens brought in from both these districts show gold. These outlying districts are all anxiously awaiting completion of the new railroad into Searchlight in order to reduce the cost of operation which has been a serious drawback up to this time.

Searchlight, May 21.

NYE COUNTY.

(Special Correspondence).—There are five leases being operated on Stray Dog at Manhattan. All are sacking and shipping ore to the smelters. Returns on Lease No. 3 show a good average on 10 tons, and on the dumps of this lease there are sacked for shipment 20 tons of the same character ore. On Lease No. 1 of the Stray Dog, John D. Campbell reports 500 tons of ore blocked out. On this lease, at the 108-ft. level, they have one and a half feet of ore that it is claimed will run $175 per ton.

A strike was made a few days ago on the Virgin Mary Fraction of the Manhattan Consolidated Extension Mining Co., adjoining the Manhattan Consolidated. At a depth of 60 ft. a 12-ft. vein of ore was cut showing gold. The ore is schist with stringers of quartz. Work in the shaft of the Manhattan Consolidated was stopped a few days ago at a depth of 75 ft. owing to a large flow of water, and work cannot be resumed until pumps are in place. Water is now assured for the contemplated mill. Two hoists are in the course of construction on the Consolidated. The dry washer which is at work on Lease No. 3, of the Cowboy is giving satisfaction. The dirt is thrown on a screen at the top of the machine, sifted onto a shaker, then deposited on riffles. A bellows sending an intermittent current of air across these riffles blows off the sand, the gold being deposited at the bottom. Considerable iron is also caught and the gold is separated by quicksilver after being taken from the riffles.—On the Raycraft lease on the Little Grey, a 12-ft. vein of good-grade milling ore has been encountered.—The hoist on the Mustang claim is ready for service. Good milling ore is being taken from the shaft on this property.—The drift from the shaft on the Georgey group of the Manhattan Nevada Gold Mines Co. is in 41 ft., and the entire face is in ore. The large black quartz ledge seen on the surface has not yet been encountered. It is expected that the next five feet will reach it.—A contract for a 50-ft. shaft on the property of the Manhattan Express Mining Co. has been closed.—The Manhattan Georgey Extension Mining Co. has been incorporated. The company's holdings adjoin the Georgey group at Central. Development will be started on the Oregon Fraction.—The tunnel on the Consolidated Manhattan, at East Manhattan, is now in 52 ft. in milling ore. They have tapped four veins. That at the face of the tunnel

is the best encountered, and pans free gold.—Work on the Buffalo is progressing. This property, the Consolidated Manhattan, and the Manhattan Mammoth are supposed to be developing the same vein.

Manhattan, May 24.

TEXAS.

PRESIDIO.

(Special Correspondence.)—The Texas Almaden Mining Co., at Terlingua, are now running ore through their new 20-ton furnace and have recovered 15 flasks of quicksilver after having fired only 21 days.—The Chisos Mining Co. are operating the leased Coquitt Tignor 10-ton furnace continuously and have installed a new gasoline hoist at the mines.—In the Marfa & Mariposa Mining Co.'s Mariposa mine an open fracture was encountered in one of their lower levels; through this fracture issues a strong blast of air. The fracture must be at least 50 ft. long to connect with the nearest workings.—— On the Lone Star property, good ore is now being taken out, and they will soon start their retorts again.

Coal developments are attracting a great deal of attention in this district at the present time. T. P. Barry and associates, who are using a diamond-drill in exploring their property, speak very highly of the results they have obtained, and the rumor is prevalent that a railroad project is well under way for this district.

OREGON.

LANE COUNTY.

An air compressor and drills are to be placed at the Doctor mine, in Blue River district, owned by C. F. Candiani, of Portland. Dr. Candiani has men running a 350-ft. cross-cut tunnel at the Doctor mine at a depth of 400 ft. As soon as the ore is opened up a stamp-mill will be installed. It is thought this will be done sometime this summer.

WASHINGTON.

STEVENS COUNTY.

Sparks' brothers of Kettle Falls have bonded the Benvenue group to Spokane parties who will put in a steam hoist and work double shifts. The owners have shipped three carloads of ore while doing development which has netted more than $40 gold per ton. The property is situated five miles southeast from Kettle Falls.

CANADA.

ONTARIO.

At the Micmac mines the drifting for the month of April is reported to have opened up something over $100,000 in ore. What the management believes to be the record for drifting in quartz and whin-rock (dike), was broken in the 300-ft. level east during the month. This drift was driven 101 ft. in 26 double shifts with a 2¼-in. machine drill, handled by one man. The cost for running this drift was $2.35 per foot, including its proportion of the pumping and hoisting expenses. The 15-stamp mill is running night and day on quartz taken out in development work.

BRITISH COLUMBIA.

Boundary ore shipments for the week ending May 19, were somewhat smaller than usual, the figures being: To Granby smelter, from Granby mines, 14,505 tons; from Skylark mine, 30 tons. To British Columbia Copper Co.'s smelter from Mother Lode mine, 2,240 tons; from Emma mine, 66 tons. To Dominion Copper Co.'s smelter, from Brooklyn-Stemwinder mines, 2904 tons; from Rawhide mine, 396 tons; from Sunset mine, 693 tons. To Nelson smelter, from Emma mine, 198 tons. Total for week, 21,032 tons; total shipped for year to date, 484,911 tons. Boundary smelter treatment of ore was as follows: Granby smelter, 15,986 tons; British Columbia Copper Co. smelter, 2719 tons; Dominion Copper Co. smelter, 3,393 tons; total treatment for week, 22,098 tons; total treatment for year, 496,614 tons.

The Risdon Iron Works, of San Francisco, have started up their new 7-ft. dredge on the Baggett ground at Oroville. This dredge is one of their latest designs and shows a number of new features, which will repay investigation. The ground is the hardest known in the Oroville district, and has been avoided by several mining companies on account of this fact. When the pit was being excavated for this dredge, dynamite had to be used, but it was a pleasure to see the dredge start up just like a clock, and it is digging right into the hard ground without any particular effort. Anyone seeing the broken portions of boulders coming up in the buckets, can realize how hard the ground must be, and how strong the dredge that can excavate such material. This dredge has been a long while under construction, namely, six months, owing to its being impossible to get the raw material from the East, but it is a credit to the builders in every way.

Personals.

Richard Pearce is in London.

Thos. H. Leggett is at Chicago.

J. W. Mercer is in San Francisco.

Thos. J. Barbour is in New York.

Robert T. Hill is at Truckee, California.

H. DeC. Richards is at the Engineers' Club, New York.

D'Arcy Weatherbe is at Oroville, studying dredging practice.

O. H. Fairchild, of Denver, is in Nevada on professional business.

Leo Von Rosenberg returned to New York from Arizona on May 23.

Jas. W. Abbott is at Los Angeles, on his return from Rhyolite, Nevada.

A. C. Beatty has returned to New York from a short holiday in Europe.

Arthur Winslow sails from Boston on June 7 for a holiday in Europe.

L. A. Decoto is making a mine examination near Salmon City, Idaho.

A. J. McCone is now at Reno, in charge of the Nevada Engineering Works.

M. B. Holt has returned to Silverton, Colo., from Denver and the East.

William B. Phillips is manager of the Chisos Mining Co., Terlingua, Texas.

Ralph Nichols is now consulting engineer to the Avino Mines of Mexico.

Stanley C. Dunn has been appointed geologist to the Government of the Sudan.

R. M. Simmons is manager of the Texas Almaden Mining Co., Big Bend, Texas.

Clifford G. Dennis is with the Marfa & Mariposa Mining Co., at Terlingua, Texas.

Hudson H. Nicholson has returned from a long trip in Mexico; he is now in Idaho.

Jack Dawson still manages the Terlingua Mining Co.'s mines at Terlingua, Texas.

Alfred N. Newell is managing the Lone Star Mining Co.'s property at Terlingua, Texas.

B. A. Laselle has returned to Barkerville, B. C., from mine examination in Peru and Bolivia.

W. M. Bainbridge, superintendent of El Paso mine, Cripple Creek, is doing jury duty at Denver.

Newton B. Knox is on his way to Japan, where he will have an office, care of Pollak Bros., Yokohama.

G. H. Rotherham has gone to Redding, California, to take charge of a testing plant for the Delta Consolidated Co.

W. W. Allen is leaving New York to take charge of the mines of the Caucasus Copper Co., in Russian Caucasia.

Jas. W. Hill of Pasadena, accompanied by Thos A. Varden of Kennett, Shasta Co., Cal., has been in Nevada City the past week.

G. A. Denny has severed his connection with the General Mining & Finance Corporation. His office is at 603 Consolidated Bldg., Johannesburg.

E. C. Musgrave has resigned as superintendent of the Tyee Copper Company and will practice as consulting mining engineer at Victoria, B. C.

G. D. Doveton, of Doveton & Purington, is at present engaged at Vantrent, California, upon metallurgical examinations on behalf of the American Smelter Securities Company.

Books Received.

Minerals and How They Occur. This is the title of a new book on a subject that is of interest and importance to every student of mining, and to every prospector. It has been written by a distinguished authority, W. G. Miller, Provincial Geologist of Ontario, Canada. It is really a treatise on both mineralogy and geology, as not only are descriptions of the principal minerals and rocks and means for their identification given, but also their occurrence in the field, a feature which will be particularly useful to the beginner. The illustrations, both line drawings and half tones, are excellent, and have been selected with care. Although the territory covered by the work is almost wholly confined to Eastern Canada, the principles are applicable anywhere. This valuable little book will be sent to any address by the Mining and Scientific Press upon receipt of the price, $1. The Copp, Clark Company, Limited, Publishers, Toronto, Canada.

Notes on the Rocks and Minerals of Michigan. This is a handbook intended to accompany the sets of mineral specimens loaned to the high-schools of Michigan by the College of Mines. It is a neatly bound, excellently printed and well illustrated book of 100 pages, 5½ by 8 in. in size. Apart from its immediate purpose, for which it is obviously well designed, the book will be found valuable to anyone interested in the iron and copper deposits of Michigan. In a clear, concise manner it gives an account of the general geology, the mode of occurrence of the ores and the description of the many interesting minerals associated with them. The book was prepared largely by Frederick E. Wright, formerly instructor in the College, but now on the U. S. Geological Survey, Mr. Wright acting under the direction of A. E. Seaman, professor of geology. The price is only 50 cents.

Trade Treatises.

Chalmers & Williams, of Chicago, issue Catalogue No. 1, Section F, which is devoted to concentrating machinery. The pamphlet is particularly well prepared and attractively illustrated.

Smooth-On, an instruction book, fifth edition, has been issued by the Smooth-On Manufacturing Co. of 572 Communipaw Ave., Jersey City, N. J. Smooth-On is a cement for repairing breaks in iron and steel, and this little book explains its use.

The B. F. Sturtevant Co. of Boston, Mass., have issued bulletin No. 48 descriptive of the Sturtevant exhaust head, a device designed to separate the water and oil from exhaust steam by the utilization of centrifugal force. This device cannot fail to be of interest to users of steam power. The Sturtevant Co. have also issued Bulletin No. 75, on mechanical draft, what it is, and what it does. Both bulletins will be sent on application.

Commercial Paragraphs.

The Electric Railway & Manufacturer's Supply Co. has established offices and warehouse at 619 Howard St., San Francisco, and are prepared to supply vulcanized fiber for dredge friction clutches.

The Compressed Air Machinery Co., of San Francisco has erected a new building at Jessie and Ecker streets, and will be able to furnish Giant drills and repair parts, Giant air compressors, Brownell engines, boilers, electric and steam mining hoists and general mining machinery by June 15. Orders for repairs of Giant drills can be filled now. Word Bros'. Drill Maker and Sharpener can be furnished at short notice. Temporary office is at 415 Fillmore St., San Francisco.

The General Electric Co. have their main Pacific Coast office in Union Savings Bank Bdg., Oakland, and a branch at 1759 Geary St., San Francisco. They have leased a half block of land at Emeryville (Oakland) and are now spending about $30,000 for temporary quarters to take care of the large consignments of material. Already 59 carloads have arrived and from 30 to 40 more have left the principal works of the company at Schenectady, New York.

Crocker-Wheeler Co., of Ampere, N. J., recently shipped direct to San Francisco, a carload of their Form L motors ranging in outputs from ¼ to 3 h-p., to be used in the re-building. These motors are now being sold from the company's temporary office, 2611 Broadway, by Mr. H. C. Baker, Crocker-Wheeler manager, in the San Francisco territory. The company is now building at Ampere, N. J., the fourth or last of the 4,000 kw.-alternators ordered by the California Gas & Electric Corporation. Three of these machines, installed in the suburb of San Francisco, successfully weathered the recent disaster.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 10 Bacon Block, Oakland, has official reports of the following United States patents issued to Pacific Coast inventors:

820,614.—Metal Saving Machine—J. Balbers, Los Angeles, Cal.
820,754.—Non-Refillable Bottle—G. C. Allen, Port Townsend. Wash.
820,467.—Step Ladder—W. F. Beal, Los Angeles, Cal.
820,129.—Concrete Block Making Machine—M. Rice, Los Angeles, Cal.

Standard Books

—ON—

MINING, METALLURGY, GEOLOGY, CHEMISTRY, SURVEYING, ENGINEERING, ETC., OF TECHNICAL VALUE TO PRACTICAL MEN.

Any of these books will be mailed postpaid on receipt of price to any address. Remit by draft, check or money order to

MINING and SCIENTIFIC PRESS

OF SAN FRANCISCO.

Berkeley, California.
420 McPhee Bdg., Denver, Colorado.
1362 Monadnock Block, Chicago.
921-24 Park Row Bdg., New York City.

If you don't see the name of book you want in this advertisement send the name of it to any one of the above addresses and we can doubtless procure it for you.

Detailed description of the following works is not deemed necessary. They are standard and the best on their respective subjects.

ASSAYING.

Assayer's Guide.
Lieber; 283 pp. $1.50

Assaying, Aaron's—Part 1—Gold and Silver Ores
Fifth edition; rewritten and improved; 143 pages; illustrated.....$1.00

Assaying, Aaron's—Parts II and III—Gold and Silver Bullion, Lead, Copper, Tin, Mercury.
Third edition; revised and rewritten; new type; new illustrations; new matter.....$1.50

Assaying, Notes on.
290 pp.; Ricketts and Miller....$3.00

Assaying with the Blowpipe, Quantitative.
E. L. Fletcher; 140 pp.....$1.50

Manual of Practical Assaying.
H. Van F. Furman; 463 pp.....$3.00

Manual of Assaying, for Beginners.
W. L. Brown.....$2.50

CHEMISTRY.

Chemistry of Cyanide Solutions.
Clennel; 160 pp.....$2.50

Chemical Arithmetic, Elementary, 1100 Problems.
S. Lupton; 170 pp.....$1.25

Chemical and Metallurgical Handbook.
Cremer and Bicknell; 250 pp....$3.50

Chemist's Pocket Manual.
Meade; 170 pp.....$2.00

Engineering Chemistry.
400 pp. Stillman.....$5.00

Elementary Course in Chemistry.
Ira Remsen; 270 pp.....80c

Elementary Textbook of Chemistry.
Mixter; 440 pp.....$1.50

Inorganic Chemistry.
850 pp. Ira Remsen.....$3.00

Inorganic Chemistry for Beginners.
Roscoe and Lunt; 150 pp.....75c

Laboratory Manual; Principles of Chemistry for Beginners.
G. M. Richardson; 150 pp.....$1.25

Manual of Qualitative Chemical Analysis.
Ladd; 82 pp.....$1.00

Manual of Qualitative Chemical Analysis.
Fresenius; 748 pp.....$5.00

Organic Chemistry.
Richter; 2 vols.....$6.00

Pocket Book for Chemists.
Thomas Bayley; 200 pp.....$2.00

Quantitative Chemical Analysis.
F. A. Cairns; 168 pp.....$2.50

Quantitative Chemical Analysis.
T. E. Thorpe; 160 pp.....$1.50

Qualitative Chemical Analysis.
Clowes; 300 pp.....$4.00

Volumetric Analyses.
F. Sutton; 400 pp.....$5.00

Western Mill and Smelter Methods of Analysis.
Argall $1.50

MINERALOGY.

Catalogue of American Localities of Minerals.
Dana; 52 pp.....$1.00

Handbook of Rocks.
Kemp; 175 pp. $1.50

Lithology; Manual of.
Williams; 308 pp.....$3.00

Mineralogy Simplified.
Erni and Brown; 383 pp.....$3.00

Minerals and How They Occur.
Miller; 252 pp. $1.00

Minerals; How to Study Them.
Dana; 380 pp.....$1.50

Mineralogy.
Brush and Penfield; 312 pp.....$4.00

Mineralogy, Crystallography and Blowpipe Analysis.
Moses and Parsons; 240 pp.....$2.50

Systematic Mineralogy.
Hunt; 390 pp.....$5.00

Textbook of Mineralogy.
Dana; 592 pp.....$4.00

MINING.

Accidents in Mining and Their Prevention
Abel; 700 pp.....$4.00

Argentiferous Lead.
Metallurgy of; Eissler.....$5.00

Blasting, and Use of Explosives.
Guttman; 600 pp. $3.75

Economics of Mining.
A discussion, edited by T. A. Rickard;; 420 pp.....$2.00

Field Testing for Gold and Silver.
Merritt $1.50

Gold Mining, Business: Organization of.
Brown $10.00

Hydraulic and Placer Mining.
Wilson; 235 pp.....$2.00

Hydraulic Gold Mining.
Kirkpatrick; 46 pp.....$1.00

Low's Technical Methods of Ore Analysis.
264 pp. $3.00

Mine Pumps and Drainage.
Behr; 168 pp.....$1.50

Mine Ventilation.
Wilson; 150 pp.....$1.25

Miners' Handbook.
Milne; 440 pp.....$3.00

Miners' Pocket Book.
Powers; 500 pp.....$3.50

Miners' Pocket Book.
Lock; 474 pp.....$4.00

Manual of Minerals, Mines and Mining.
Osborn; 369 pp.....$4.50

Manual of Mining.
Ihlseng; 714 pp.....$5.00

Mine Foreman's Handbook (for Colliers).
Mauchline; 300 pp.....$3.75

Mine Examiner and Prospector's Companion.
Miller; 387 pp.....$3.00

Mine Surveying.
Brough; 368 pp.....$2.50

Ore Dressing.
Richards; 2 vols., 1220 pp.....$10.00

Prospectors' Field Book and Guide.
Osborn; 310 pp.....$1.50

Prospectors' Hand Book.
Anderson; 176 pp.....$1.50

Prospecting, Locating and Valuing Mines.
Stretch Cloth $2.00
Pocket Flexible leather $2.50

Practical Hand Book for Miners.
Miller; 234 pp.....$3.00

Practical Mining.
Murphy $1.00

Practical Surveyor's Guide.
Duncan; 214 pp.....$1.50

Practical Treatise on Hydraulic Mining.
Bowie; 312 pp.....$5.00

Quartz Operator's Hand Book.
Randall; 240 pp.....$2.00

Sampling and Estimation of Ore in a Mine.
Rickard; 222 pp.....$2.00

Surveying: Theory and Practice of.
Johnson; 800 pp.....$4.00

Surveying: Treatise on.
Gillespie; 600 pp.....$2.50

Text Book of Stone and Ore Mining.
Le Neve Foster.....$10.00

Tunneling.
Drinker; 1200 pp.....$25.00

Underground Treasures, and How to Find Them.
Orton; 145 pp.....$1.50

Well Boring for Water, Brine and Oil.
Isler $4.00

ELECTRICITY.

A. B. C. of Electricity.
Meadowcraft; 75 pp.....50c

Arithmetic of Electricity.
Sloane; 150 pp.....$1.00

Dynamo; How Made; How Used.
Bottone; 80 pp.....$1.00

Electro-Metallurgy.
Gore; 418 pp. $2.00

Dynamos and Motors: Practical Management of.
60 pp.....$1.00

Electricity and Magnetism.
Nichols and Franklin; 303 pp....$2.00

Electrical Power Transmission.
Bell; 700 pp.....$4.00

Electrical Engineers' Pocket Book.
Foster; 1000 pp.....$5.00

Electrical Transmission of Energy.
Abbott; 550 pp.....$4.50

How to Make a Dynamo.
Crafts; 70 pp.....75c

Practical Electricity.
Ayrton; 270 pp.....$2.50

GEOLOGY.

Aids in Practical Geology.
Cole; 450 pp.....$3.00

Chemical and Geological Essays.
Hunt; 300 pp.....$2.50

Economic Geology.
Tarr; 525 pp.....$4.00

Elements of Geology.
Le Conte; 660 pp. $4.00

Genesis of Ore Deposits.
Posepny; 600 pp. $6.50

Geology Applied to Mining.
Spurr; 326 pp.....$2.00

Geology, Principles of.
Lyell; 750 pp.....$8.00

Geology for Beginners.
Watts; 344 pp.....$1.00

Geology Applied to Mining.
326 pp. $1.50

Manual of Geology.
Dana; 450 pp.....$5.00

Manual of Mineralogy and Petrography.
Dana; 400 pp.....$2.00

Minerals and How to Study Them.
Dana; 380 pp.....$1.50

Nature of Ore Deposits.
Beck; 2 vols., 685 pp.....$8.00

Ore Deposits of the United States.
J. F. Kemp; 470 pp.....$5.00

Ore Deposits.
A Discussion; 90 pp.....$1.00

Treatise on Ore Deposits.
Phillips and Louis; 800 pp.....$7.00

MILLING.

Cyanide Process.
Park; 192 pp.....$2.50

Cyanide Process.
Wilson; 200 pp.....$1.50

Cyanide Process.
Bosqui; 260 pp.....$2.50

Cyanide Process.
Eissler; 180 pp.....$3.00

Cyanide Process.
James; 175 pp.....$5.00

Cyaniding Gold and Silver Ores.
Julian & Smart; 405 pp.....$6.00

Chlorination Process.
Wilson; 125 pp.....$1.50

Gold Milling Practice.
Preston; 100 pp.....$1.00

Gold, Milling of.
Locke; 820 pp.....$10.00

Handbook of Gold Milling.
Louis; 600 pp.....$3.50

Lixiviation of Silver Ores.
Stetefeldt; 210 pp.....$5.00

Stamp Milling of Gold Ores.
Rickard; 260 pp.....$2.50

Treatment of Gold Ores.
O'Driscoll; 210 pp.....$2.00

SMELTING.

Electro-Metallurgy.
McMillan $3.50

Hydro-Metallurgy of Copper.
Eissler; 700 pp.....$4.50

Lead and Copper Smelting, Copper Converting.
Hixon; 128 pp.....$3.00

Lead Smelting.
Iles; 228 pp.....$2.50

Metallurgy, Handbook of.
Schnabel; 2 vols., 1500 pp.....$10.00

Modern Copper Smelting.
Peters; 642 pp.....$5.00

Matte Smelting.
Lang; 100 pp.....$2.00

Metallurgy of Lead, Desilverization of Base Bullion.
Hofman; 558 pp.....$6.00

Metallurgy of Silver.
Eissler; 620 pp.....$4.00

Metallurgy of Lead and Silver.
Collins; 700 pp.....$4.50

Metallurgy of Gold.
Eissler; 665 pp.....$7.50

Metallurgy of Gold.
Locke; 820 pp.....$10.00

Metallurgy of Gold.
Rose; 650 pp.....$6.50

Metallurgy of Silver, Gold and Mercury.
Eggleston; 3 vols., 1500 pp....$15.00

Production and Properties of Zinc.
Ingalls; 328 pp.....$3.00

Pyrite Smelting.
A discussion, edited by T. A. Rickard; 310 pp.....$2.00

EDITORIAL.

WE HAVE RECEIVED many letters of sympathy in regard to the recent disturbance. Two are worth quoting. Says one friend: "May you live long and may you never prospect." But we hope to do both; life is a mortal malady, and those who seek shall find. Another: "I appreciate your loss, but we are glad to know that your square-sets were well lagged up." Yes, there was a bad cave, sure enough, but the levels were kept open and we are pushing forward a new cross-cut that is expected to strike ore on July 7.

THE INTIMATE RELATIONS existing between the Pennsylvania Railroad and the companies that ship coal over its lines have been exposed before the Interstate Commerce Commission at Philadelphia; and the evidence goes far to show why certain independent coal dealers have been harassed by inability to get cars until their business was destroyed. Important officials of the great Pennsylvania Railroad system have accepted blocks of stock in companies that desired to propitiate them. It is high time that such practices were properly labeled. As *The Evening Post*—the most intelligently outspoken paper in America—says: "The officers of the Pennsylvania have subjected their shippers to elaborate and systematic blackmail."

OUR CONTEMPORARY, *The Iron Age* remarks on the lack of linguists in the foreign trade of America. This suggests the similar want in the mining industry. There was a time when French and German were the languages most needed, and as regards general culture they still hold pre-eminence, but to a mining engineer whose mother tongue is English, the second language should be Spanish. The great mining regions of the world today are in countries where either English or Spanish is spoken. We are among those who believe in the continued growth of mining in Spanish America; English and American capital is being diverted in large sums to Mexico, Central America and to Colombia, Peru, Bolivia and Chile. A mining engineer who is ignorant of Spanish will find himself severely handicapped in the extension of his field of activity and many men otherwise well equipped for important positions will lose them for lack of this linguistic accomplishment. The young fellows in the profession should acquire knowledge of Spanish.

EACH WEEK we publish, under the heading of Mining and Metallurgical Patents, a description of the latest devices and ideas applied to mining and metallurgy, and never a week passes but there is something contained in this illustrated page of patents which is of interest and value to the mining community. This time the patents include a new departure in classifiers, patented by Charles W. Merrill. The classifiers previously invented by Mr. Merrill, and used by him at the Homestake plant, are large conical vats, and although they were set on secure foundations, the slightest settling on either side resulted in disturbing the even flow of pulp over the upper periphery of the cone, and prevented proper classification of the sand and slime. To obviate this Mr. Merrill employed various materials in making the rim of these cones, but not meeting with satisfactory results, he tried sheet-lead—and the problem was solved. Any subsidence of the classifier, disturbing the overflow, can be quickly adjusted by carefully planing the soft metallic edge of the overflow rim. This is but one of a number of patents, all of which are interesting to some of our readers.

THE ATLANTIC MINE has finally succumbed to air-blasts. These are due to the violent expulsion of air from workings in which the hanging wall has collapsed. They occur in mines that have a large extent of worked-out ground, which has neither been filled with waste nor securely timbered. When they happen, the vibration is communicated to the surface and a miniature earthquake results. We have described these occurrences more than once, and we refer to the matter again because the mining and financial press tell of "severe earthquakes experienced in the copper region" of "fifty-seven seismic shocks" and of "the great alarm" felt in that part of Michigan. Of course, the people of Houghton and Hancock know the causes of the tremors and do not confuse them with recent occurrences—in Japan, for instance. Anyone who has been in the Atlantic or has seen a longitudinal section of the workings will readily understand why the ground has caved, until the mine has had practically to be abandoned. The lode has been stoped for a width of 15 feet, and over an area 5,000 feet along the strike and 2,500 feet on the dip, with other workings even beyond these limits. The levels are timbered, but the stopes are bare, with a foot-wall sloping at 54 degrees. No wonder the increasing weight of the overhanging rock has gradually crushed the mine and made these juvenile earthquakes. But it is a matter for widespread regret, for the Atlantic has long been a proud example of economic mining in America. With ore containing only 11 pounds, or about half of one per cent, of copper, the Atlantic managed to keep above water and with a yield of less than one per cent, a profit was won. This mine was long associated with the name of John Stanton, who organized the company to work it in 1872 and directed its business affairs up to his death recently. He took a legitimate pride in its cost record and it is a pathetic coincidence that both succumbed so nearly together.

The Trouble at Cananea.

The untrustworthy character of a certain type of newspaper is illustrated by the lurid reports sent broadcast over the country from Cananea. That irresponsible paper, *The Examiner,* came out with positive statements that 45 Americans and 55 Mexicans had been killed and more than twice that number wounded in a fierce battle, that stores had been looted and machinery dynamited. And worse than this, that Mr. Arthur S. Dwight, the manager of the Greene Consolidated Copper Company, together with other members of his staff had been shot down by a multitude of Mexican miners. Local newspapers all over the country copied this rubbish and so caused great anxiety among the friends of those who live at Cananea. And now, as trustworthy news comes slowly, it appears that the brothers Metcalf and seven Mexicans were killed in a small riot, everything is quiet and operations have been resumed as heretofore. The episode did not close without two regrettable incidents, one being the invasion of an armed party of Americans who had been misled by reports and thought it necessary to go to the rescue—incidentally falling foul of Mexican troops. The other was the action of the Western Federation of Miners which in convention assembled, passed a resolution of sympathy with the Mexican rioters under the delusion that they were battling for "industrial freedom." As regards the first, it is well known that the Mexican authorities are quick to repress such disorders and keep a much firmer hand over the unruly spirits in the mining camps than is the case on this side of the Rio Grande; in fact, the rural police is usually most efficient, and even the regular troops are quick to act—except as to the Yaquis. The other se-

quel to the Cananea trouble was foolish indeed, for it was cowardly to express sympathy with a rabble that was reported to be killing our own people in murderous fashion and it was silly to greet them as co-workers for "industrial freedom." No freedom, industrial or otherwise, is won through such means or by such sentiments.

Since the above paragraph went to press, we have received a telegram from Mr. Dwight, who informs us that the trouble is settled and that the excitement has subsided. All departments of the Greene Consolidated Copper Company are in operation at about three-quarters the usual capacity. The only destruction of property to be recorded was the burning of the lumber-yards by the mob, the loss being estimated at $100,000. At one time the entire industrial camp and town were threatened by 2,000 Mexicans on the rampage, but the situation was saved by the prompt action of the American employees who, as auxiliaries of the local police, dispersed the rioters and subsequently aided the authorities in maintaining order, until the next day, when General Ysabel, the Governor of Sonora, arrived. The General came escorted by two hundred Americans from Arizona, who had voluntarily placed themselves under his orders. Regular Mexican troops reached the spot later on the same day, and thereupon the gentlemen from Arizona withdrew, so as to avoid international complications —their withdrawal being as honorable as their arrival had been timely. It is not too much to say that the behavior of the Americans during the crisis was generally marked by self-restraint and good sense. The State and military powers are now in full control and deserve great credit for their attitude during a trying time. No further trouble whatever is anticipated.

All of this is excellent news and most welcome. Cananea is the scene today of one of the most interesting applications of American technical skill, and we trust the professional men who are directing the important mining and metallurgical operations will be enabled to bring them to full and continued fruition without further interruptions of any kind.

Following the Pay-Streak.

In this issue we publish an article which deals with the experiences of a mine superintendent in doing his best to find ore and to follow it. Mr. Nickerson writes as one who has been there and his description will appeal strongly to those who have known the ups and downs of a mine superintendent's life, the eager interest of watching a new cross-cut that is on the point of cutting the vein a hundred feet or more below the last level, the wretched depression of driving a drift for hundreds of feet without finding pay-ore and the keen exhilaration when the miner at the face hands forth a piece of the real thing. And it is not all accident. No man can put ore into ground, but he can use much skill in tracing that which has been deposited there. We are reminded of a day long ago when as manager of a small mine, we were able to announce the finding of a pocket so rich that it cost $200 to extract $20,000 in two weeks. The directors wrote letters of a character needlessly complimentary but when, later, other similar discoveries were not chronicled in the reports from the mine, they wrote complaining of the manager's remissness. They got a reply that, so we afterward heard, astounded them by its frankness, for they were told that the manager had not been consulted at the time the ore was formed in the lode and that therefore he was not responsible for the scant distribution of rich stuff, while holding himself liable for criticism if he did not extract it at a minimum cost when found. But that, as we have said, was long ago—before the days when managers were kept busy making estimates of their ore reserves. Nowadays the instinct or knowledge which enables a miner—call him superintendent or manager, if you like—to find ore and, having found it, to stick to it closer than a brother, is at a discount. People do not value a mine by its probabilities, by the chances of a bonanza or the possibility of a pinch, they send out a lot of clever young men who sample, assay and compute, while another fellow casts his eye over the results and calls it so many tons of such and such stuff. The opinion regarding the chance of finding more ore or the judgment of approaching impoverishment are either avoided by the engineer as dangerous to his reputation or else they are so buried among figures and maps that they are overlooked. We do not undervalue the importance of correct sampling as one of the factors in the appraisal of mines, in fact, good evidence has been given elsewhere as to our conviction to the contrary, but in truth there are many more men nowadays who can take samples accurately than there are those who know how "to follow the pay-streak"; and after all, is it not putting the cart before the horse? If it were not for a few good miners—engineers and superintendents—willing to spend lots of time underground and to watch the changes in drifts and cross-cuts from day to day, with a transit in one hand and a map in the other, we should have precious little ore to sample, whether by good methods or bad. Mining companies that can secure the services of the man who finds ore can usually pay for the help of fellows to sample it in most approved fashion.

The appointment of Mme. Sklodowska Curie to the professorship of physics at the Sorbonne, in succession to her late husband, is an event the romance and pathos of which cause it to appeal to the interest of the scientific world. Mme. Curie is still young and is the first woman to hold a professorship in the celebrated French university. It is said that she and her husband were on the eve of a new achievement at the time of his unhappy death by a street accident. We hope the lady will add fresh laurels to a head already crowned with distinction. From the days of Hypatia and St. Hildegarde, from those of Mary Somerville and Caroline Herschel, women have occasionally been represented among the original investigators, but as a rule they have either been handicapped by husbands that were unsympathetic or obscured by the great men who were the partners of their work. Hypatia suffered for her beauty, so it is said; and in a modern instance a woman of rare mental gifts paid the penalty of her womanhood, for Sonya Kovalevsky gave up marriage to take a chair in the University of Stockholm and, in 1888, received the Prix Bordin from the French Academy of Science, an award made in utter ignorance of the fact that the winner was a woman. Yet at this supreme moment of her career as a scientist, when acclaimed by her intellectual peers and honored by the community in which she lived, she learnt that her lover, the spectator of her triumph, actually in the crowd that gave her an ovation, had withdrawn his suit because unwilling to accept a subordinate position in her interest. This was too much for her woman's heart and she died, a broken creature, two years later. Which brings up the question whether the gain to science outweighs the loss to humanity when a woman becomes a highly specialized intellectual machine.

By the Way.

At a recent meeting of the American Association for the Advancement of Science, an interesting paper was read by Mr. Fullerton L. Waldo on the 'Present Conditions and the Prospect' of the Panama Canal. We quote from it:

The total yardage excavated on the Panama Canal to date is about eighty million cubic yards. The yardage that directly applies along the canal route as finally determined is about forty-one millions. On the 80-ft. level plan, this means that about 28% of the big ditch has been dug; on the 60-ft. level plan, about 23%; on the 30-ft. level plan, about 19%; on the sea-level plan, about 16%. In the roundest kind of round numbers, this leaves about 185,000,000 yd. still to be excavated for a sea-level canal; 140,000,000 for the 30-ft. level; 110,000,000 for the 60-ft. level. The time required, according to John F. Wallace, is twelve, ten and eight years, respectively. The cost would be: sea-level $230,475,725; 30-ft. level, $194,213,406; 60-ft. level, $178,013,406. The yardage cost, 54.7c., is based on the following figures: Installation of plant, 1.5c.; mining, 11.2c.; loading material, 11c.; transportation to dumps, 11.5c.; dumps, 4.5; maintenance of track, 8.4c.; general expense, 6.6c. From May 1, 1904, to May 1, 1905, about 650,000 cu. yd. were excavated. The United States assumed control May 24, 1904, so these figures practically represent what was accomplished during the first year of American occupation.

The enemies of the canal project are legion, and to the friends of the inter-oceanic waterway—which has now become an accepted fact—the description I have just quoted of the conditions that obtain at Panama seems like a jeremiad of the kind the congressional obstructionists delight in. But he who reads between the lines will not find in the generally trustworthy and unbiased account of the engineer referred to any particular reason to be disrouraged about the canal.

Mr. Morison, who saw things in a big, broad way, realized that when once the Americans took over the control of the canal zone, they would, with characteristic American impetuosity, be in altogether too much of a hurry to 'make the dirt fly,' adopting the popular slogan. Morison deprecated haste. He insisted that we must take two years to clean up the mess made by the Spaniards and the French—to burn the hovels, to drain the swamps, to petrolize the breeding-places of the mosquito, to build clean, wholesome houses for the men. He went down there himself and put his fingers into the dry-rot, and found there the seeds of his own mortal illness. Whitewash could not fool him, whether it covered the walls of a pesthouse or whether it concealed some mishandling of canal affairs. A great many men, since Mr. Morison died, have paid tribute to his absolute honesty, and his passion for exact statement based on accurate observation. Had Morison lived, he might have been able to check the tendency to 'hustle,' in the scrambling ambition to make dirt fly simply that the foolable part of our country's population might be deceived by a specious appearance of 'something doing.' All calamity-howlers to the contrary notwithstanding, the canal is as sure to be built as a natural law is certain of fulfilment; and those who today busy themselves trying to find arguments against it are going to be ashamed and sorry when the seas are eventually linked by the greatest engineering undertaking in the history of mankind. For a canal which saves nine thousand miles of ocean journey between San Francisco and New Orleans, six thousand miles between Yokohama and New Orleans, two thousand miles between Hong Kong and New Orleans and six thousand miles between Sydney and New Orleans, is an agency in bringing mankind nearer to mankind too vastly important to evade the sight of God and escape the desire of nations. But just now, rather than any statement of cubic yards excavated in August or September or October, one finds the following figures significant:

In June, 1905, there were 62 cases of yellow fever on the isthmus; in July, 42; in August, 27; in September, 6; in October, 3. In August, 1905, with a force of 12,000 men at work, the death-rate was two-thirds of one per 1,000, whereas under French regime, in August, 1882, with a force of 1,900 men, the death-rate was no less than 112 per 1,000. These figures will appeal to the citizens of a community whose recent fight against yellow fever has been the admiration of the civilized world and a great object-lesson to uncivilized humanity; an object-lesson in civic self-dependence, public spirit and uncommemorated heroism. A city that can pass through such an ordeal, a city that faces a great crisis as New Orleans faced the yellow-fever epidemic, is the surest guarantee that the nation of which that city is a part will do her duty by civilization, and build, expeditiously and economically, the Roosevelt Canal.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

The waters of Lake Tahoe are not available at Virginia City without pumping, the latter being at a slightly higher altitude.

Concrete is often useful about the collar of a mine-shaft and underground as well. Water-tight bulkheads may be made of concrete if properly constructed.

Pure hematite contains 70% iron. Magnetite is higher in iron content—72.4%, but hematite is generally preferred by the manufacturers of pig iron.

At times the cost of hydraulicking at the North Bloomfield gravel mine, in Nevada county, California, was as low as 2.86c per cu. yd., or about 2c. per ton.

Annual assessment work may be done on a patented claim for the benefit of an adjoining unpatented claim, the same as if done on another contiguous unpatented claim.

Mining claims cannot be located within any of the National parks, such as the Yosemite and Yellowstone parks, or any of the military reservations, but claims may be taken within the forest reserves.

Two parts linseed oil, four parts tallow and one part graphite, is said to make an excellent compound for lubricating the teeth of gears. It should be applied hot with a brush when the gears are in motion.

Silver—native, and as chloride and sulphide— is found in fossil fish, wood, and other fossilized objects in Texas, Kansas, Utah, in the Ural mountains of Russia, and elsewhere, and always, so far as observed, in the rocks of Permian age.

Stopes on veins of limited width are usually wider than they are supposed to be, or at any rate, wider than they are reported to be, which may account in many instances for the differences between the estimated recoveries and the actual results in the mill.

Not infrequently an assay of ore shows the presence of both gold and silver, but where the ore is treated in a plate mill, the bullion resulting from amalgamating on the plates will show a higher fineness in gold than is indicated by the assay of the ore, for the reason that ordinarily a higher percentage of gold is saved than of silver.

The amount of assaying necessary to determine the value of a newly discovered vein, depends upon its extent, and the character of the ore. If the vein varies greatly in width, and the ore ranges from a few cents or dollars into the hundreds of dollars per ton it would require a great many more assays than in a case where the vein was of nearly uniform width, with little variation in the character of the ore.

The Scots builder, planning a new hotel within sight of Arthur's Seat, knows from the teaching of geology that it was so many thousand years ago that the rock on which Edinburgh Castle is founded was hurled up from the plain. What he cannot tell is that a like cataclysm shall never shake Scottish fields. The risk is there for all builders on the thin surface; the laws of its variance have not yet been coded.

The law requires that a discovery of mineral be made within the limits of the location claimed, but it is not necessary that the 'discovery' shaft be sunk at the point of initial discovery, as the claim owner may find a better place to do this work than where he first comes upon the vein or ore deposit. This discovery shaft must be on the vein, however, and disclose mineral-bearing rock in place.—Taylor vs. Parenteau, 23 Colo. 368. 48 Pac. 505.

No class of men in new mining regions do more to retard the development of mines than those who stake all the ground they possibly can, regardless of the rights of others. Those who would locate and work on claims, if they could have the opportunity, are unable to buy out these wholesale locators and do not wish to take issue with them at law for obvious reasons, though their case would in most instances be won in the courts. Local rules should limit the number of claims which one person could locate.

A stockholder in a mining company who held no fiduciary or confidential relations or position with the company, that might give him an insight into the private business of the company, may locate the claims owned by the company upon their failure to perform the annual assessment, as required by law, either for himself, or for another, and any one may purchase the claim from such re-locator with perfect safety, but care should first be taken to ascertain that the property was really subject to re-location by the aforesaid stockholders, or any person at the time such re-location was made, and that neither the company nor any other person had performed the annual assessment.

Hot air rises, but when the several shafts of a hot mine are connected by underground workings, as on the Comstock, some of these shafts must necessarily be downcasts. The shaft of the Consolidated California and Virginia mine, known as the C. C. shaft, situated in Virginia City, is a downcast, and the Combination shaft, several thousand feet distant, and sunk vertically in the hanging-wall country, being connected with the Consolidated Virginia workings, at the Sutro tunnel level, is an upcast. The collar of the Combination shaft is higher than that of the Consolidated Virginia. There are numerous other shafts on the lode, which are connected by workings. Some of these are upcast and some are downcast.

Electric as compared with steam heating: Using a good boiler and properly covered supply-pipes, radiators will utilize 60% of the total heat units contained in coal. On the other hand let us, supposing we use an electric heating system, employ a first-class condensing engine developing one horsepower by the burning of two pounds of coal per hour, we shall recover 10% of the heat units in the form of heat energy. Allowing for the friction of the engine, the loss of efficiency in the dynamo and the loss in transmission (line loss), only 50% of this energy is given forth as heat by the electric radiator or 5% of the original heat units. Therefore, but one-twelfth as much heat is recovered by electric heating as by direct steam radiation.

If district mining recorders would personally visit and inspect each claim, the certificate of location of which is offered for record, and see that the claim, as indicated on the ground by stakes or monuments, does not conflict with previously located claims, much unnecessary litigation would be avoided. We never knew of more than one district mining recorder in the United States who did this, and he lived in Madera county, California. He refused to record any claim located in his district without first having made a personal inspection of the corners, and ascertaining that no conflict existed. His charge for such examination and recording was $5 for each claim. He did no surveying, merely visiting the corner monuments of the claim. There were no conflicting titles in his district.

A true metamorphic rock has not been really fluid in the generally accepted sense of that word. At the most the effect of pressure and heat have made it slightly plastic so that it has yielded and slipped a very little. Therefore, when it re-crystallized, the materials did not move far in the rock. If there were in the original sediments successive layers of different nature (such as dark ferruginous mud beneath clean quartz sand) the re-crystallized rock will often preserve the banding; the mud will appear as a dark layer of crystalline ferruginous minerals and the sand bed will be represented by crystalline quartz. Banded structure in metamorphic rocks may also be produced by more active crystallization along slipping planes than in the rest of the rock.—J. E. Spurr.

Occasionally in working a gulch placer deposit the pay, which has become poor, suddenly improves on striking a change in bedrock. When this occurs it may be attributed to one of two causes; either the character of the bedrock forms a better riffle for catching and holding the gold, or the bedrock is itself auriferous, being, in fact, a vein or zone of gold rock. Generally the former would be the safer conclusion, as, if the latter were true, it is probable that the good pay would not begin immediately upon coming to the vein, but gold would be found on the bedrock below it. It is possible however, that the latter may be too smooth to constitute good bedrock and any gold reaching it from the up-stream side would be carried over it, as might easily occur in case of a hard rock, worn smooth by the rushing water and grinding sand.

It is customary, in pan mills, to run amalgamating pans from five to seven times as fast as settlers. Agitators run still more slowly than the settlers. The speed of revolution of each of these devices is a matter for determination by experiment. In the pans the consistency of the pulp and the speed of revolution must be such that the 'quick' is constantly lifted from the bottom and thoroughly mixed with the pulp, avoiding flouring by either excessive grinding or too long continued stirring. In the settler fresh water is added to thin the pulp so that the mercury, with its contained amalgam, may separate from the pulp, settling to the bottom. In the haste of discharge, the pulp often contains finely divided quicksilver, and this the agitator is expected to settle from the greatly thinned pulp. Too rapid revolution of the agitating device will result in defeating the object sought. No arbitrary speed of revolution can be given, it must be suited to the material being treated in each case.

Where a locator lays his claim across the strike of the vein, he may amend the location so as to conform to the true strike of the vein, provided no other locations are made adjacent to his own, but as soon as the surrounding ground is taken by others, he may no longer 'swing' his claim to conflict with these existing rights. His side-lines then become his end-lines, and he has no extra-lateral right. He may work his vein downward within the side-lines until a point is reached vertically below that end-line of the claim which lies in the direction of the dip of the vein. He may, however, still amend his location so as to take 600 ft. on the vein—the distance between the original side-lines, rejecting all but 300 ft. on either side of his vein, thus making a claim 600 ft. square. Should he decide to take advantage of this provision of the law, he may take his extra-lateral right on the 600 ft. section of the vein, but he cannot have both the extra-lateral right and the surface area, 600 by 1500 ft. too, under circumstances such as described. He must relinquish one or the other.

In the operation of crushing rolls care must be taken that open spaces, of greater width than the distance between the rolls themselves, are not allowed to form at the ends of the rolls (between the rolls and the cheek plates), by the improper adjustment of bearings or springs. Cheek plates of hard wood are considered superior to those of metal, by some concentrator men. Also the speed of rolls must be adapted to the material being crushed. The tendency is to speed them up beyond the limit of greatest efficiency, and loss of capacity is caused both by the rebounding of the fragments of ore and by slipping. What is technically known as the 'angle of nip', is important in setting rolls. This angle should be as nearly constant as possible, and this can only be approximated by screening the ore before sending it to the rolls. The angle of nip on lumps of the same size will vary with the diameter of the rolls, and with the distance between them. The efficiency of the rolls depends more largely upon this 'angle of nip' than upon any other one consideration in the operation of crushing rolls.

Petroleum lands may be located under the law applying to placers. For this the United States law provides as follows: "Any person authorized to enter lands under the mining laws of the United States may enter and obtain patent to lands containing petroleum, or other mineral oils, and chiefly valuable therefor, under the provisions of the laws relating to placer mining claims: Provided that lands containing such petroleum, or other mineral oils which have heretofore been filed upon, claimed, or improved as mineral, but not yet patented, may be held and patented under the provisions of this act, the same as if such filing, claim, or improvement were subsequent to the date of passage hereof." The statutes contain no special law relative to discovery on oil-bearing lands, but the courts have recognized the rights of bona fide locators who have taken up land reasonably supposed to be oil-bearing, either by reason of discovery of oil, or of an oil-bearing geological horizon within such lands, or which may reasonably be expected to extend under such land, from neighboring lands previously proved to be oil-bearing, and locators of such lands may remain in possession of their claims so long as they diligently prosecute the work of exploration by means of sinking a well on the land for the purpose of actually discovering the oil-bearing stratum at some point beneath the surface.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

THE TREATMENT OF A GOLD-BEARING ANTIMONY ORE.

The Editor:

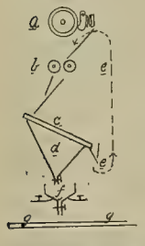
Sir—As a supplement to the very interesting and valuable paper on the 'Separation of Gold in Antimony Ores,' which appeared in your issue of April 28, it may be of interest to describe the way in which were obtained the concentrates on which Mr. Mason did a portion of his work.

This antimony gold ore, as it occurs at the mine, may be divided into two classes:

1. High-grade ore, carrying 40% antimony or over, and separated by hand-sorting.

2. Low-grade ore, being the refuse from the high-grade ore, and that ore in the mine which cannot be sorted by hand to a 40% product. The high-grade ore has been sold to smelters and the low-grade ore left in the mine or on the dumps. About 20 tons of the low-grade material were sent to me for concentration. Various methods of crushing and concentrating were tried, by which it was demonstrated: (1) That the ore must be crushed dry, and that as soon as it is crushed to the required size it must be removed beyond the possibility of further crushing. (2) That the coarsest screen must be used which will allow of a separation of the mineral from the gangue.

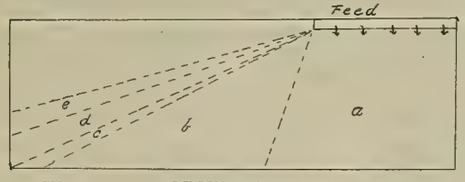
The following was the method finally adopted:



a. Rock breaker.
b. Rolls.
c. Shaking screen, 24-mesh.
d. Bin for undersize.
e. Elevator for oversize.
f. Tank for mixing undersize with water.
g. Wilfley concentrator.

The screen used was twilled battery-screen wire-cloth of 24-mesh and about No. 26 wire. The mill in which these tests were made had been idle for several years and the belting, etc., was continually getting out of order, making it impossible to obtain a steady run. The Wilfley table used was one of the earliest patterns made and difficult to adjust. Any man who has attempted concentration under the above conditions will readily understand the difficulty of obtaining good results.

The separation of the various products on the table was complete, as shown in the following sketch giving as products:



a. Slime.
b. Sand.
c. Middling (returned).
d. Stibnite } Concentrate.
e. Metallic antimony }

The results were as follows:

	Mineral Contents		Weight		Total Gold dollars	Total per cent	Total Antimony pounds	Total per cent
	Gold per ton dollars	Antimony per cent						
Ore	7	6.2	6.5 tons		43.75		775	
Concentrate	24	50.5	1,400 lb.		16.80	38	700	90
Sand	4	1.0	10,655	"	21.31	48	100	12
Slime	18	5.0	444	"	7.99	18	20	2

A number of tests were made on the tailing, that is, sand, from this concentration to determine the practicability of extracting the gold therefrom by means of potassium cyanide or postassium cyanide and bromo-cyanide. The most important of these were as follows:

1. Four assay tons (120 grams) of sand through 24-mesh were agitated in a closed vessel for 24 hours; strength of cyanide solution 0.2%. Extraction equals 30 per cent.

2. Four assay tons (120 grams) of sand ground through 100-mesh were agitated in a closed vessel for 24 hours; cyanide 0.2%. Extraction equals 50 per ecnt.

3. Eight assay tons (240 grams) of sand ground through 100-mesh were agitated in a 0.2% solution of potassium cyanide and 0.1% bromo-cyanide for 36 hours. The solution was tested at the end of 24 hours and made up to initial strength in cyanide and bromo-cyanide. Extraction (based on assays) equals 80%. Extraction (based on gold precipitated and recovered) equals 75 per cent.

Further work on a large scale using bromo-cyanide on other ores has convinced the writer that there would be no difficulty in carrying out commercially the results of the above test No. 3. The treatment of the low-grade ore would therefore seem to resolve itself into a system of dry crushing and concentration, obtaining: (1) Concentrate, treated by some such method as Mr. Mason suggests; (2) Sand, treated, after regrinding, by bromo-cyanide; (3) Slime, which contains no metallic antimony, could be leached with caustic soda as Mr. McArthur proposes and the residue, thus freed from antimony, added to the sand No. 2 and cyanided.

Halifax, May 26, 1906.

EARTHQUAKE SOUNDS.

The Editor:

Sir—Referring to your editorial in the issue of the 24th ult., on 'Earthquake Sounds,' I am reminded of what I heard and saw of the earthquake in California in 1872.

At that time I was engaged in making my surveys for the large scheme of irrigation for the San Joaquin valley. I was camped on the west bank of the San Joaquin river between Bantas and Stockton, and south of the Central Pacific Railroad. I was asleep in my tent and awakened by a rushing sound, like a heavy freight-train traveling at a great speed. A minute or two later (so it seemed) came a great shaking of the ground which made me jump out of bed and go to the door of the tent. I then saw the water in the river thrown from bank to bank and some of it was thrown into my tent, which was about 25 ft. from the bank. Subsequently (if I remember rightly), long lines of cracks or crevices were found on the Mono side of the Sierras.

I can remember another occurrence of this earthquake sound preceding the tremblor, when I was in India in 1866 constructing the railroad between Bombay and Calcutta. This occurred in the Nerbudda valley; then there was quite a pause between the sound and the shake-up which made me feel sea-sick.

THE MINING BOSS OR FOREMAN.

The Editor:

Sir—The discussion in your recent issues of the article of Mr. R. B. Nickerson on 'Handling Men Underground' serves to give merited prominence to the importance of the position of mining boss, or foreman; I trust it may awaken a rational consideration of a subject, the true import of which seems to be overlooked, or misunderstood, by many managers of mining properties.

I can conceive of no mining position, excepting that of manager, which is of so much significance in the operation of a mine, as that of underground boss, or foreman—a fact that is patent to every observing person of experience in the management of mines. Upon the foreman devolve many duties, the efficient discharge of which requires abilities and qualities of no ordinary character. An enumeration of some of the things he ought to know how to do and a few of the qualities he ought to possess, will establish, I believe, the correctness of my opinion as to the value and importance of his position.

He should have had practical experience to enable him to perform all kinds of underground mining in a speedy, economical and scientific manner. He should have useful knowledge of the various kinds of machinery for hoisting and pumping purposes and for operating power-drills; he should be skillful in timbering, an art of the utmost importance for both the safety of life and the physical preservation of the mine; he should have at least a fair knowledge of the minerals of commercial value found in the mine, and also of the rocks in which they occur, and of the formation inclosing them; he should be quick to detect all changes in the orebodies and the formation, and to note the results of the same, that such data may serve to guide him or the manager in determining, in accordance with recognized and accepted geological principles, the best course to pursue, because of such alterations; he should be adept in the use of all necessary tools and explosives; he should have an intuitive judgment in fixing gradients, so as to secure an easy and rapid transit of cars and to conduct the flow of water, if any, to a common receptacle; he should appreciate the value of thorough ventilation and be capable of installing the means to procure it; he ought to know the amount of work to be fairly expected from every man under him, and, he should be so considerate as to place and combine men in such a way that but little or no disproportion of labor will ensue, thus precluding apparently valid reasons for charges of purposed severity, or favoritism; he should be neither ill-humored nor patronizing, but he should try to evince and maintain a disposition regardful of the rights of the men, and yet preventive of that familiarity which destroys discipline and produces neglect; in fact, he should be able to do anything and everything underground, and should have an ambition to produce the best obtainable results without harsh methods, or without endangering the lives of the workmen, or hazarding the physical preservation of the property; and, finally, he should manifest fidelity to his manager in everything pertaining to his position, which does not involve the infraction of manly independence or of moral principle.

Such a man is of great value to the owners of a mining property, and he should receive a salary commensurate with his qualifications and the responsibility of his trust. Success or failure often depends on the foreman. It is a great mistake to suppose because a man is smart, clever, or even well educated that he can make a competent foreman and run a mine without considerable practical experience. Hence, the selection of this officer will be made with great care by any superintendent, or manager, who knows his business, and is desirous to achieve marked success. In truth, the selection and retention of a capable foreman is no slight evidence of the ability of the manager or superintendent. I hope it is opportune to observe that the qualifications to constitute an efficient foreman are to be acquired step by step, in one school only, that of ocular and manual experience.

JEREMIAH MAHONEY.

Denver, May 31, 1906.

Nickel is derived mainly from two important classes of ore: 1—Garnierite, a hydrous silicate of nickel and magnesia, of the composition $H_2(NiMg)\ SiO_4+Aq$, discovered in 1867 by J. Garnier in New Caledonia. The output of this ore had increased in 1902 to over 120,000 tons. Lately the production has fallen off owing to the exploitation of the Canadian mines. The ore tests as much as 30 to 40% nickel, but the average grade shipped is 7%; occasionally consignments as low as 5% have been exported. Moisture varies according to circumstances between 18% and 30%. 2.—Nickeliferous pyrrhotite and chalcopyrite. With the exception of a formerly somewhat important mining operation in Norway and Sweden, practically all the ore comes from the nickel and copper district of Sudbury, Ontario. The average amount of nickel is 3%, and that of copper under 2%. The Scandinavian supply above mentioned never amounted to much, and since 1891, when 125 tons of nickel were produced, it has dwindled into insignificance. Regarding the cost of manufacture of nickel from the 7% garnierite, the following figures, from private sources, are fairly correct, per ton of marketable metal: Smelting and bessemerizing, £45; grinding and calcining, £5; reducing, £5; total, £55. This does not include cost of ore, freight to Europe and standing charges of works, which amount to another £60 to £80 per ton, making a total of £120 to £130 per ton of metal.

The Cullinan Diamond was found in the Premier mine, near Pretoria, by Mr. Wells, surface-manager, in the yellow ground about 18 ft. from the surface, on January 25, 1905. The weight of the stone is 3,024¾ carats, or about 1.7 lb. troy, and the dimensions are about 4 in. by 2½ in. by 1¼ in.

The big diamond is a portion of a much larger stone, the original form of which can only be roughly guessed at. Four pieces of this original stone have been broken off along cleavage-planes, which we know to have the position of octahedral planes. Each of these fragments must have been of considerable size. Consequently, the stone itself shows only a portion of its original natural surface (called 'nyf' in the diamond-cutters' jargon), the greater portion being formed by these four flat cleavage-planes. The remaining part of the surface shows one octahedral face and a curved irregular surface roughly corresponding to six faces of the dodecahedron, while one very irregular face of the hexahedron is indicated by quadrilateral impressions which are characteristic of these faces in minerals, such as the diamond, which possess the octahedral mode of growth. The stone is a single crystal, no twinning-planes or twinning-lamellae being present. It is quite colorless, its perfect transparency being best compared to that of pure ice or of the variety of silica known as hyalite. There are a few grains (inclusions), and also some flaws, or internal cleavage-planes—'glessen,' as the diamond-cutters call them—in it, but their position is such that they do not detract from the value of the stone as a gem. It is certainly the purest of all the very big stones known.—G. A. F. Molengraaff.

Mining Soft Iron Ore Without Timber.

Written for the MINING AND SCIENTIFIC PRESS by STUART RHETT ELLIOTT.

On the Marquette range, the term 'soft ore' is used in a general way to include all iron ore that does not possess the well-marked characteristics of the hard crystalline ore of that region. The method of mining to be described is applicable to a variety of ore that drills easily, breaks and runs freely, and yet is hard enough to stand for a considerable time over a large opening.

The method is now being practiced at the Hartford mine, on the Marquette range, at Negaunee, Michigan, by Capt. James Piper. It is not, however, my object to explain the conditions at this or any particular mine, but merely the general principle involved. I am indebted to Capt. Piper and to Mr. André Formis, mining engineer for the Oliver Iron Mining Company, for many details.

Assume a soft orebody that is 75 ft. thick, that strikes east and west, and dips south at an angle of 45°. The foot-wall is a slate; the hanging is an exceedingly tough and compact jasper. The shaft is sunk in the foot-wall and the levels are turned off from the shaft at appropriate intervals. On each level a drift is driven in the foot-wall quite near to the ore and parallel to it. These drifts are shown in Fig. 1. From each drift, at intervals which depend upon the conditions of the mine, cross-cuts are run out as in Fig. 1 and driven through the ore to the hanging wall. These serve to open up the ore. One further preliminary step is necessary. Along the space of about 15 ft. just before the cross-cut passes from the foot-wall into the ore, that is, before it crosses the margin of ore on the foot-wall side, the cross-cut is enlarged into a room by cutting out the rock as shown in Fig. 2. This room is timbered and is made about two sets high and three sets long. The object of this is to afford space for the handling of the ore through chutes and the loading of cars. The timber in the lower sets near the foot should be large and strongly braced in all directions, not only to support a great weight but also to resist the shock due to the rolling down of large masses of ore.

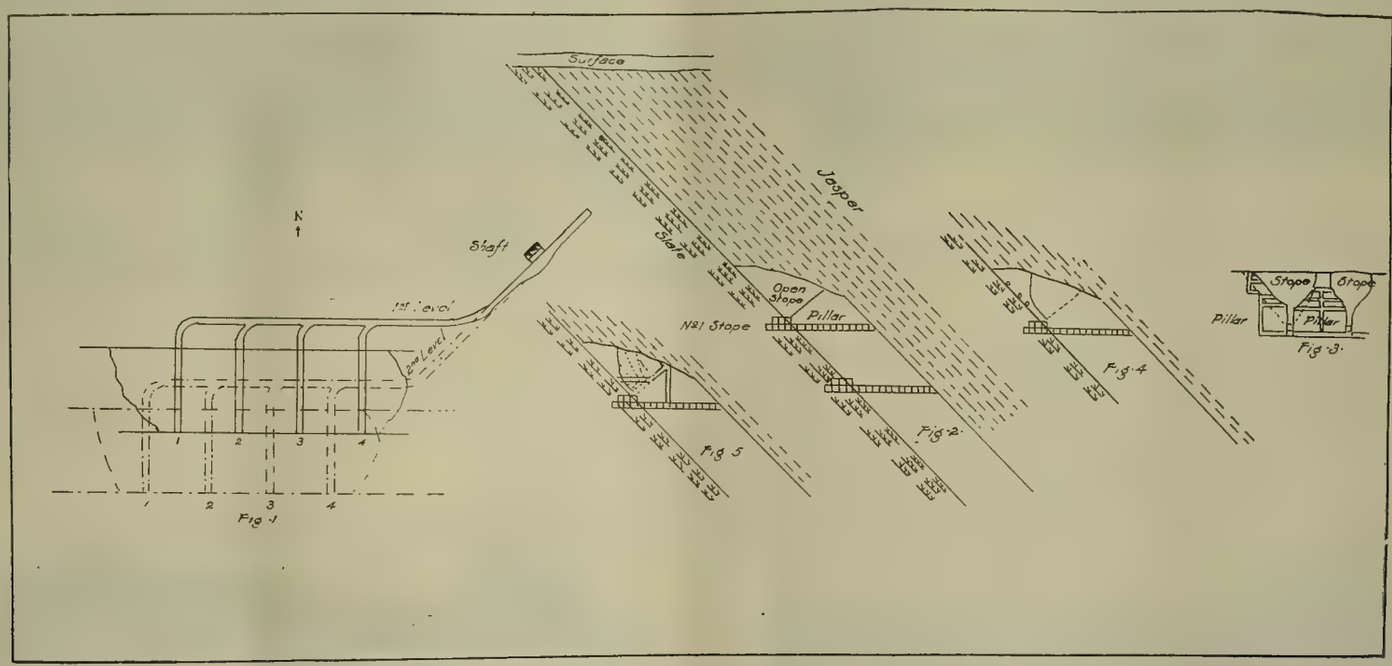
Now then; from the top of each of these rooms, a raise is started and carried up on the foot for a height of about 20 ft., its dimensions being eight feet square. From this point it is widened out in all directions so as to assume a funnel shape, as shown in Fig. 3 and 4. Long holes are drilled into the brow toward the hanging and blasted—increasing the width of the stope as it goes up. As the stope increases in height, the greater will be the area of unsupported back, and the greater will be the burden on the holes; consequently a large amount of ore will be broken with a few long holes as the stope becomes advanced. The ore is broken down in this fashion until the next level above is reached. Fig. 4 shows a cross-section of the stope. The dotted line in this figure shows the stope completed.

In order to afford ready access and egress, to and from the working places in the stopes, while this work is being carried on, a number of sub-drifts and raises are provided. A small drift is driven along the foot from the room in the cross-cut for about 30 ft., when a small raise is put on the foot for about 40 ft. From this raise a sub-drift is turned off at such an elevation that, when driven back along the foot, it will hole into the stope directly under the back of ore. See Fig. 3. A similar drift is maintained on the other side of the stope. As the stope increases in height, new drifts are turned off higher up from the raises. In this fashion drifts are always kept open immediately under the back of ore. With a drift on each side of the stope, a safe exit can always be provided and with a drift always opening into the stope close under the back, the men need never take the risk of going out into the open where the back is high, but can walk along the upper edge of the stope where the back is never more than a foot or two above their heads and a solid wall on one side.

After all the ore has been taken out that is possible by stoping from the foot, the shape of the stope resembles that of a funnel. It is now desirable to get out more ore toward the hanging. In order to do this, the miners start in from one of the lower drifts and work around in a sort of semicircle on the slope of the funnel. They start by cutting back toward the hanging, making a groove until they reach the foot-wall again on the other side of the stope. In this way they under-cut considerable ore, all of which they blast down except a small ledge left over their heads, to protect them while making another semicircular cut. As soon as this process has reached such a point that the slope is too gentle to cause the ore to run down to the chute, an under-cut is started a little higher up and carried around as before in a semicircle. Fig. 5 shows the removing of this pillar of ore. The dotted lines give the outline of the stope at different stages of the operation. An extra cross-cut is also shown. This work can be carried on until the hanging is reached, if there is no danger of the latter slabbing off, otherwise a small pillar will have to be left to protect the men. When the under-cutting and raising has been continued in a semicircle up to the hanging, all the ore below the rock or capping will naturally fall, as there is nothing to support it.

The same process of working is used in each stope in the mine. Care, however, must be taken to leave a pillar between adjacent stopes. If two adjacent stopes should hole into each other the men would be left without protection above them. The main cross-cuts on the second level should be driven so as to come under the pillars on the first level. The pillars between stopes on the first level can be under-cut and blasted, or they can be brought down by undermining in the stopes from the second level.

There still remains a pillar on the foot, a part of which will be difficult to get. It can be under-cut to a certain extent on the foot and blasted, the ore finally running down to the second level. Raises can also be put up through the foot from the main drift and a part of the ore run to the level. The men who load the cars are protected by the foot-wall and are in no danger. The ore runs down into the sets above the main drift, where it is scraped through holes in the lagging into the car below. The lagging must be particularly strong. Steel rails are sometimes used in addition to ordinary lagging.



MINING SOFT IRON ORE WITHOUT TIMBER.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rock samples from Bisbee, Ariz., marked W. V. S., are determined as follows: No. 1, Hornblende-andesite; No. 2, Syenite-porphyry; No. 3, Syenite; No. 4, Rhyolite; No. 5, Andesite; No. 6, Syenite; No. 7, (Drill Core) Diorite; No. 8, Andesite-tuff.

The interesting rock specimens from Tolo, Oregon, have been determined as follows: No. 1, Quartz-diorite, in which plagioclase feldspar predominates. The other important constituents present are hornblende and quartz. A little biotite is also present. No. 2 is the same rock but also shows some orthoclase, which would place the rock in the Grano-diorites. This differential occurrence of minerals in rocks of this description is frequent; No. 3 is more basic, containing relatively little quartz, and more hornblende. Copper sulphide, (chalcopyrite) occurs in small disseminated crystals.—As it occurs in the mass of No. 1-2, it is a segregation of minerals from the main mass; No. 4 is Diabase; No. 5, Steatite; No. 6, Marble, (crystalline limestone); No. 7, bluish Marble, otherwise similar to No. 6; No. 8, also Marble, but of finer grain. It is not probable that either 6, 7 or 8 would make good structural material, owing to the decided schistose structure developed in them. They would make good lime, however; No. 9, Diorite, much altered by weathering. The brownish spots are due to the removal of some iron-bearing constituent now indeterminable; No. 10, silicified wood; No. 11, Jasperoid. Rock of this character is not infrequently found in the vicinity of bodies of copper ore; No. 12, Pectolite; No. 13, an aggregate of scales of Sericite, (hydrous mica); No. 14 is largely composed of calcium carbonate and iron oxide. A small amount of cinnabar is seen following a seam of calcite; No. 15 is Serpentine showing numerous scales of the rhombic pyroxene, bronzite; No. 16 is finely granular silica, probably the result of the alteration of some other rock; No. 17 is Calcareous Graywhacke; No. 18 is a coarse Grit or sandstone, composed of little rounded pebbles of dark-gray flint, compactly cemented by argillaceous and limy material; No. 19 is a piece of Bituminous Shale; No. 20 is Diorite. The feldspars are mostly bright and fresh, but the hornblende is almost wholly altered to scales of chlorite. Quartz and orthoclase occur, but sparingly; No. 21 is Diabase-porphyrite; No. 22, Aplite (fine-grained micaless granite); No. 23, fragments of various rocks cemented by calcium carbonate; No. 24, ferruginous limestone; No. 25, a silicious Breccia, one side of which is altered and penetrated with iron oxide; No. 26 is a portion of a Pegmatite (coarse granite) dike. It carries a little pyrite, and may contain gold; No. 27 is Limonite. This is seemingly from the gossan of an iron-bearing lode. In one place appears a peculiar iridescence, which is often an accompaniment of gossan covering a deposit of sulphides carrying copper. No copper ore, of any kind, is visible in the specimen, however.

Manhattan.

Written for the MINING AND SCIENTIFIC PRESS by
A. H. HALLORAN.

The skilful ways of New York financiers have apparently been transmitted to the Manhattan pioneer. Refined Eastern methods have been metamorphosed in changing the scene of operations, but the result is the same,—an attempt to precipitate money from the pockets of the unwary. Yet both the stock in New York and the mine in Nevada have an inherent value that warrants careful investigation. For there is gold in Manhattan. Apparently scattered in lavish profusion over a wide area, its presence will brighten the streak in the panning of almost any part of the district. The prospector has proved its existence; it remains for capital to determine the quantity of it. To attract money, many questionable methods have been tried. It is toward some of these that my prefatory criticism is directed.

A REST-HOUSE IN THE DESERT

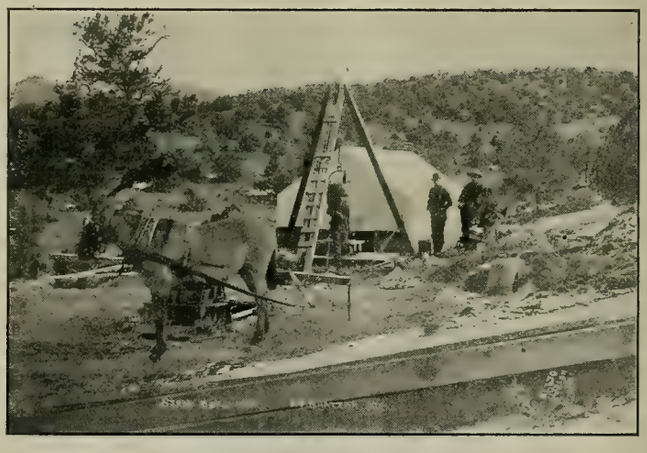
THE TOWN OF MANHATTAN.

The Manhattan mining district is 45 miles due north of Tonopah in Nye county, Nevada. It is a small area, about two miles wide by seven long, following the course of Manhattan canyon in the Toquima or Smoky range of mountains, separating Big Smoky valley from the Ralston desert. The elevation of 7500 ft. gives a cooler, moister climate than is found further south, and also some timber. The steep sheltered sides of tributary canyons support a sparse growth of pinon and juniper with some fir and mountain mahogany. This will give fuel, but it is too scrubby for mining purposes. Water has been found in wells from 50 to 100 ft. deep. It is sufficient for domestic use, but not for milling. During the current month it was delivered in most parts of the town for $1.50 per barrel. Apparently much of the water is from the melting snow which rests upon the higher points until late in the season. With the accompanying verdure it forms a pleasing contrast to the somber coloring of the desert. The Toquima range is typical of the abrupt chains corrugating what would otherwise be a monotonous expanse of desolate plain.

The general north and south parallelism of these uplifts together with the aridity of the region, have deterred the most adventurous prospector from going far from a base of supplies. Yet old abandoned workings often surprise us today as testifying to activity in the 60's and the 70's. Silver was discovered at Belmont, 12 miles to the east, in 1865. A 40-stamp mill costing $225,000 and a 10-furnace roasting plant were treating a part of this ore in 1868. The Manhattan of today is re-named from an abandoned camp on the other side of the range. Such revival is characteristic of what is taking place all through a forgotten Nevada. Its permanence is assured by the conveniences now at the miner's disposal, in contrast with the hardships undergone by his predecessors. With slow-moving ox-teams they painfully crawled over a country marked only by the bleaching bones of the few that had preceded them. An automobile now speeds over the same trail, marked by 'dead soldiers' thrown out by the thousands who have joined in the 'rush'. Freight is sometimes hauled from Austin, 90 miles to the north, but passengers usually come in by stage or automobile from Tonopah. This trip of 45 miles is made in three hours at a cost of $20 per person. The stage makes the trip in seven hours and charges $8.

Gold was discovered here in April, 1905, but it was not until January of this year that the stockbroker and real estate boomer realized its attractiveness to the capital that had been denied admittance on the ground floor of other Nevada excitements. Last December the cabins of less than a hundred prospectors marked the site of the bustling camp of today, boasting a population of three thousand men. They have come mostly from Goldfield and Tonopah, and are fully experienced in the art of booming mines. Thus it is that already Manhattan is the best advertised camp in America.

STAGE-COACH PASSING AN ORE-WAGON.



THE YOUTH OF A MINE.

So far but little actual mining has been done. Claims have been located, other claims have been re-located over them, and still other claims staked on the snow covering pre-existing claims, all blanketed with claims newly recorded since the snow has melted. Yet to many companies merely mining on paper this is as satisfactory as though they actually did own a few square feet of ground. It offers a pleasing prospect to an ambitious lawyer.

Adverse weather conditions and a wild scramble for locations have prevented geologists from making a detailed study of the district. While in the camp I had an opportunity to go over most of the ground and through the best developed claims. The oldest rock is evidently a granite; deposited apparently upon this, is a great series of altered sediments, including schist, quartzite, shale and limestone. Covering these are great extrusive masses of rhyolite and other igneous rocks. The sediments and later extrusives are crossed and recrossed by a network of zones of silicification, some of them auriferous. Gold may be found in any or all of these rocks. To the south of the line followed by Manhattan canyon the bedding dips at an angle of 45° south; to the north of the same line a comparable sedimentary series dips at a similar angle to the north, except in places where the dip has been reversed by the rhyolite. A prominent limestone bed can be traced in an almost perfect ellipse around the camp. Its continuity is interrupted in places by the rhyolite flow.

Such evidence warrants one in reconstructing the district as an anticline or 'turtle back' fold, the eroded axis of which is now approximately followed by Manhattan canyon. A cursory survey shows this to be but one of a great billowy series of similar uplifts extending for miles along the range. In many places they have been obliterated or displaced by the great flows of rhyolite. Both before and since this igneous extrusion the physiography has been carved during long periods of erosion so as to lose all semblance of its original form. The sedimentaries have been determined as pre-Cambrian, the rhyolite as Tertiary. The uplift and subsequent erosion occupied the interval between these periods. Mineralization has been the most recent of all events in this history. Both the rhyolite and the sedimentaries are freely mineralized along zones of fracture.

There is not yet sufficient evidence to justify the statement that the great areas of granite to the south have been the cause of the uplifting and metamorphism of the sedimentaries, for this may have been effected by subsequent intrusions of certain silicious fine-grained dikes carrying but few bi-silicates. The deeply eroded surface of the upturned shales shows that the anticline was formed long before the great outpourings of lava. This lava consists chiefly of rhyolite and tuff.

The stratified rocks are limestone, shale and quartzite; they have a thickness of at least 6000 ft. The limestone is mostly a compact dark-blue rock, usually fine grained. It contains many small seams of white crystalline calcite. Often it has been largely replaced by silica. A yellowish dolomitic limestone was observed as a narrow bed in the shales and schists to the south. The shale has been much metamorphosed and presents

every phase from soft shaly limestone to hard contorted schist. The quartzite is but an indication of the great silicification to which the district has been subjected; when jasperoid, it is seldom metalliferous.

The rich ore follows closely the line of a silicified limestone bed near its contact with a red schist. These bedding veins course approximately east and west, with numerous north and south connecting cross-fissures. The wonderfully rich gold specimens have usually been found at the intersections of these vein-systems. The workable ore is a silicified lime containing cavities filled with calcite and fluorite crystals, the gold showing beautiful crystalline forms on these. The ore is spotted and 'pockety' in character. In some cases the lime has been

SACKING ORE AT MANHATTAN.

crystallized to marble and forms the foot-wall. Evidently there have been two periods of mineralization, first, one in which great silicification took place with little gold deposited except in pyrite crystals, and later a deposition of gold, fluorite and calcspar from ascending vapors or solutions, the latter forming the high-grade deposits. Some of the bedded veins are 30 ft. wide and offer good milling propositions. The high-grade ore is found in narrow veins.

But little development wo.k has been done, and that mostly by lessees. On the Union No. 9 a shaft down 160 ft. has opened up some high-grade ore. A cross-cut tunnel and shallow shafts on the April Fool—the discovery claim—have disclosed high-grade ore. The Manhattan Consolidated G. M. Co. has opened up a fine body of milling ore in the Silver Pick. It may be a coincidence, or otherwise, but the best showings follow the ellipse roughly outlined by the Portland, Annie Laurie, May Flower, Big Pine and Reilly Fraction, Jumping Jack and Stray Dog, Union No. 9, Little Grey, Mustang, Chipmonk, April Fool, Litigation hill claims, Silver Pick and Pine Net. Sulphide ores have been opened up on the Iron King and Iron Queen. These properties also contain the yellow dolomitic limestone previously mentioned.

From some of these and other properties some high-grade ore has been sacked, forming an imposing barricade around the whim or windlass. Much of it is in the same place it was three months ago. Very little has been shipped, because the pictures of the sacked ore are possibly more impressive than the smelter returns. Unfortunately a great many 'wild-cat' companies have been formed, their only mining being confined to working possible investors. Nevertheless, there are a few good companies engaged in legitimate mining. One purposes sinking a prospecting shaft to a depth of 1000 ft. to test the continuity of the ore. Others are erecting hoists and will start development work. Until this has been done Manhattan mining will remain a precarious gamble.

Gypsum occurring in metal-bearing veins is a result of decomposition of some calcium-bearing mineral, possibly calcite, or the lime in some felspathic rock present in the vein or in the walls, and which has been acted upon by sulphuric acid derived from decomposition of sulphide minerals. Gypsum has been known to occur in gold, silver and copper-bearing veins, but it has no important significance.

A New Method for the Purification and Softening of Water.

At the present time, in all the large industries, there is a growing demand for pure water. The time when any kind of water was considered good enough to feed into boilers has gone by, and experience has shown that even a comparatively large expenditure is justified if, by such an outlay, a water may be obtained which will not leave a deposit of scale in the boiler. To this end, various boiler compounds have been invented which, by their action, produce a flocculent precipitate, instead of a hard scale when evaporated in the boiler. This flocculent precipitate may be blown out through the mud-drum and leaves no ill effects, as it will not clog the tubes. The present methods of obtaining such a precipitate, however, are not of the best, as they necessitate the introduction into the boiler of various chemical compounds which in themselves add greatly to the volume of foreign matter which it is desired to get rid of, and often strongly corrode the boiler-plates and tubes.

There is another kind of water which, while not leaving a scaly deposit, is just as bad in its effects, if not worse, as it tends to destroy the boiler-tubes completely, instead of filling them up with scale. This is water of a slightly acid reaction. It will be seen, therefore, that a process that will eliminate the greater part of the salts held in solution and at the same time give the water a slightly alkaline reaction, accomplishing this result without the addition of chemicals, would be a great boon to most of the industrial enterprises of this day. Such a system has just been invented and it is the purpose of this article to describe it in detail.

The process is an electrolytic one and unites in a single apparatus all the advantages of efficient filteration and cheap electrolysis. Although there are other processes which accomplish good results, they are not altogether electrolytic in their action and consume so much current that they are prohibitive for adoption on a large scale. This new system will purify and soften water at a cost not exceeding 1½ cents per 1,000 gal., computed for the most obstinate of waters and on the prevailing charges of the New York Edison Company for electricity.

The electrolytic action causes the precipitation of the principal scale-making compounds, found almost everywhere in water, consisting of: Sulphate of lime (gypsum), carbonate of lime, carbonate of magnesia, phosphate of lime, iron oxide and silica. The passing of the hard water through the apparatus causes the precipitation of most of the mineral substances above described, the acidity is destroyed and the iron deposited at the cathode.

The new process, instead of driving free oxygen from the water, liberates an excess of this important element, which, owing to the shape of the positive electrode, is kept in contact with the water and eventually is re-dissolved. This has the effect of strongly vitalizing the water and at the same time sterilizing it, owing to the bubbling through it of ozonized oxygen generated at the anodes, it being a well known fact that nascent oxygen is one of the most active of germicides. Another important factor which tends to rid the water of bacteria and make it suitable for drinking, is the precipitation of solid matter; this tends to carry down with it other substances held in solution and effectually clears the water of organic matter.

The apparatus consists of a cylindrical iron tank divided into two parts by a vertical partition. The anodes are baffle-shaped plates of iron, the cathode being the wall of the tank itself. By this arrangement the hydrogen, liberated at the cathode, has free access for escape, while the oxygen, liberated at the anode, is held in confinement until enough has accumulated to overflow into the surrounding water. The solid matter is precipitated to the bottom of the tank while the treated water overflows to the filter contained in the other half of the tank, thus making a very simple and easily transported outfit. This process is controlled by the Electric Water Purifying & Filter Company of New York City.

A PROSPECTING SHAFT.

All rocks, even sandstones, do not break equally well. Gillette says a cut six feet wide was made in sandstone with drill-holes spaced three feet apart, thus requiring 4½ ft. of hole per cubic yard of rock. In seamy rock, shallow holes four to six feet deep were drilled, and from two to three sticks of 50% dynamite charged in each hole. The cartridges were one and one-half inch diameter and eight inches long. In solid rock, the holes were drilled eight to ten feet deep and double the amount of dynamite used.

Following the Pay Streak.

Written for the MINING AND SCIENTIFIC PRESS by R. B. NICKERSON.

There are veins that seem to have been made to serve as illustrations for those who teach mining by books. They present ideal conditions. The veins are of a good size to work, say five or six feet and pitch at an angle of 50 or 60°. The walls are hard and firm and the vein pursues the even tenor of its way in a stately and dignified fashion in length, breadth and depth. Very little water is encountered in the development work, but there is an abundance at hand for power, with timber, etc. in the immediate vicinity. To complete this pen picture we will say that the ore is free-milling and goes $25 per ton. This is the kind of a mine that the honest miner had in his mind's eye when he remarked "Damn a mine that won't pay under any kind of management." Coming down to stern realities, it may be remarked that mines answering this description resemble the visits of angels in that they are few and far between. They are the good things, which like the buffalo seem to have long since disappeared from the face of the earth. They are the kind of mines that cause the fortunate investor to regard mining as a good thing and to assure his friends that "legitimate mining is no gamble, but an industrial proposition."

But how different from the foregoing description are the real conditions that usually confront the miner! All kinds of difficulties must be faced. The veins are uneven and irregular, often consisting of a system of streaks difficult to understand or follow. Separated by horses, displaced by dikes and faults, many feet apart, it is no wonder that orebodies are missed, overlooked, or lost. Wet, heavy ground is encountered requiring large pumping plants, and a forest of timber is used to hold the ground up. The cream of the mines, the rich surface ore, further enriched by erosion and oxidation, is all gone. The miner must sink deep shafts or run long tunnels in order to open up bodies of lower grade ore—often so low-grade that, after equipment and months of development, the expense when subtracted from yield, leaves but a small margin of profit and that profit possible only when the closest and most rigid economy has been observed. The patient and long-suffering stockholder feels that mining is not all his fervid imagination had painted. Let us suppose that a mine has been worked for years at a profit, and while it may still be paying, the management deem it advisable to sink a new shaft or drive a new adit to tap the vein deeper than the present workings, in hopes of finding orebodies below. The work is done and the miner finds himself hundreds of feet below the old workings and in virgin ground. If a perpendicular shaft has been sunk, he starts his cross-cut to intersect the vein formation. The crucial moment has arrived. The development work has not been done without a great deal of deliberation and planning, in which expert opinion has been called in from the outside and paid for. The work has cost thousands of dollars. Obstinate and conservative members of the board of directors have been argued with and brought over to the new plan; and now the time has arrived when any stroke of the pick may uncover the much-coveted prize—a good orebody. The life of the mine depends upon what the development work will discover. To the superintendent who has faith in the mine and has recommended the work, it is a trying time. There is no rest for him now. The vein is struck with a rush of water; so far so good. The fissure is open, but what a disappointment! The gouge is there, but without ore; the formation is dull and dry looking. The quartz is glassy and brittle with no life in it; it contains some sulphides, but they are not the right kind. It is evident that there is no orebody here; it must be found elsewhere.

One way to prospect a mine in the condition just pictured, is to cross-cut the vein formation and drift on the foot-wall, making cross-cuts at intervals of every 50 or 100 ft. so as to test the formation up to the hanging wall and a little beyond it. But in mines when the lode-channel is large, this is often a very expensive method, as the cross-cuts must be hundreds of feet in length to get to the hanging wall. Hard slips are met with, carrying gouge and quartz, resembling the vein and making it impossible to be certain that they are the main hanging wall, and that there may not be an orebody beyond. It is necessary to drive cross-cuts at comparatively short distances apart, for an orebody might lie between any two of them. But there are several ways to kill a cat, and the experienced miner knows that an orebody resembles a tree in that its feeders spread in all directions from the main mass. Whatever cause, whatever convulsion of nature opened the fissure so that a place was made for the ore deposit, it also made its pressure felt for hundreds of feet from the main ore deposit. It is an interesting study to examine the formation surrounding a worked-out orebody, and it is instructive also. There is generally, even in the same mine, something distinctive and characteristic about the formation of each individual orebody, peculiar to itself. Even the mineral constituting the separate orebodies will vary, and can be recognized by one familiar with the mine. It is interesting to follow, where possible, the drifts, raises, etc., leading to a worked out orebody. Test the filling of the fissure by panning, observe the formation and see just where the first indication of ore appeared. It will frequently be found hundreds of feet from the shoot. The pocket miner puts this knowledge to practical use in following the paystreak to the pocket. All quartz mines resemble each other in this respect, both gold and silver and some lead mines. The orebodies throw off their feeders just as the pocket does, and while it is often a difficult matter to follow them, if once a streak of gold quartz is found and followed it will sooner or later lead to ore, that is, in most mines. Some veins never were any good and never will yield an orebody. The feeders are there, but they do not bunch. These mines are strictly no good, but if a vein has made one good orebody it is a strong argument that it will make another. But it is often a delicate matter to follow these feeders. Many complications and difficulties are met with. One is literally groping in the dark. Much experience and judgment are required. It has often happened, especially in the old silver 'chloriding' days when men worked on the tribute system, that after a certain part of the mine had been considered thoroughly prospected by the company, a party of miners working on a lease of the ground and by following these little pay-streaks, would strike ore. Large and valuable orebodies have been found in this way, that probably would never have been found in any other way.

In the case cited, the cross-cut is being driven ahead and the old reliable gold pan is brought into play and everything thenceforth is panned and prospected. The development work goes ahead testing the vein, and every method known to modern mining is used to crowd the work ahead. Gasless powder is used. The steam-pipe to the pump and water-column are tapped, and a steam-jet and small water-pipe are run to the face. Extra men are put on to throw back the waste, to lay track, pipe, etc., so that a cross-bar can be set up at once and the back holes drilled while the waste is being shoveled. The best men, the pick of the mine, are put on the job and no expense is spared to rush the work in every way possible. The panning goes on, but not a color of gold is found and the assays yield nothing. A water-hose is run out to the end of the waste-dump and carloads of the muck are washed over to get a good look at the formation, but it looks dry and dead. The panning goes on, and finally one morning a tiny speck of gold is seen in the pan. Where did it come from? More pannings are made, but with no results. Finally a pan is washed with several little specks in it and in the washings is found a little piece of a bluish looking quartz, not a quarter of an inch cube, with a speck of galena in it. Down in the mine goes the superintendent and every inch of the last round blasted is gone over with painstaking care. Ah! Here it is! A tiny streak of gouge, not thicker than a knife-blade! He tries it with the point of his candlestick and finds a little grit. A handful is taken on top and carefully panned, and he sees something that sends a thrill of exultation through him. None of your little specks this time, but a good prospect! Plenty of fine gold and a few coarse colors! But he is suddenly chilled with the thought that it may be coming from the ore above; that it is nothing but the drizzle end of that ore giving out. Never mind, it must be followed, so down in the mine he goes and gives his orders, "When you set up again, boys, put your round in the cross-cut and drill another round here in the side from the same bar. We will start a drift here"; and the drift is started following the paystreak. These are anxious days for the superintendent and his foreman. The men share in the tension. They realize the importance of the work. They know why they were put there and what is expected of them and they bend their brawny muscles over the throbbing drill and work as men nowhere else do underground. The drift goes ahead, following that tiny thread of gold as it turns its tortuous way through the formation. Other seams and slips come in, but the right one must be picked out. The 5-ft. rounds frequently leave it to one side or the other, but it must be found again. The "old man" has left word that he is to be called whenever they blast, day or night, and when the watchman raps lightly on his window and says, "You are wanted below, sir, they just blasted," he is up and down in the mine again to find that the last round lost the streak. A slip has cut it off, slick and clean. Now begins a hunt to find it. Which way did the slip cut it? From this way, of course. He gouges in on the slip and pans the gouge on a shovel-blade. There is the gold. He drills on the slip, several rounds, maybe, following the gold. Finally the slip does not pan any more and he looks for the pay-streak. There it is. He knows it at a glance this time. The same tiny streak of gritty gouge. Ahead again, and so on through all its erratic, winding course he traces and follows it with skill and patience; sometimes lost for days at a time, but always picked up again. Finally it begins to assume something of a definite shape. The walls become more regular and distinct; the gouge is thicker, more water follows the streak and there is more quartz showing up. It continues to improve. More water comes in. The quartz is soon a foot thick and prospects fine. A hay-maker could follow it now. The "old man" gives orders to blast the waste first, muck back, blast the ore and send it to the mill and says, "Boys, I think we have made a strike here." He writes to the company that good ore is coming into the south drift and it looks favorable. It is all ore now and all going to the mill. The plates brighten up. The ore from the drift is sweetening the low-grade ore from the other stopes and the mill-boss says: "Can't you give us a little more of that rock from the bottom? That's good stuff."

When he goes to the bottom and stands in the drift running through the orebody, a feeling of pride and satisfaction comes over him. He was right. His judgment was correct. It is a strike, sure enough. There is no doubt of it. He feels "some proud" as he surveys the length and breadth of it. There is ore enough in sight to insure the prosperity of the mine for several years to come. He feels a personal interest in it. He found it and he knows how easy it would have been to have missed it many times, and that the ore might have lain undiscovered for years and might have never been found.

This is one way to find ore. It is going back to first principles. It has this advantage: It does not necessarily require a chemist, a geologist, or a mining engineer to do it.

Mining in the High Sierra.—There are a large number of 'base-ore' deposits in the Sierra Nevada, in California which only require capital, development, and modern metallurgical methods and machinery to make them profitable enterprises. Although these ores are usually spoken of as 'base,' they are mostly the ordinary sulphide ores in quartz gangue, generally consisting of the sulphides of iron, copper, zinc, and lead, together with silver and gold, arsenic, and occasionally antimony is found in some of these deposits, but they are in no sense more difficult of treatment or of less value than many of the ore deposits that have been successfully worked under similar conditions for years in Colorado. They are situated at high altitude—8,000 to 13,000 ft., being mostly between 9,000 and 11,000 ft.; but mines are being worked in Colorado at this altitude, and even much higher, with no particular regard to the hardships of the situation. The Californian is accustomed to mines at lower altitudes—1,000 to 3,000 ft.—and the high Sierra has few charms for him. The Colorado, Montana and Idaho miners look upon long winters, deep snows, high winds, snowslides, and the other vicissitudes of high altitude as a matter of course and are satisfied if the mine will yield a profit, as a great many of them do, under these disadvantages of climate and isolation.

Detection of Adulteration in Cement.—The simplest test for adulteration is to examine the cement under a small three-lens pocket magnifier. To do this, spread the residue obtained by sieving 100 to 200 grams of cement through a No. 200 sieve on a piece of black glazed paper and move the lens over it. The particles of well-burned clinker will appear black or brown in color, and of a waxy or vitreous luster, and spongy looking, resembling coke or gum arabic. The particles of clinker are always rounded. Slag usually presents a greenish of bluish color, and the edges of the particles are much sharper than those of the bits of cement clinker. Limestone and cement rock, if present, are in flattened particles, and the latter is always dark gray in color. Both of these may be readily detected by effervescence with dilute acids. The foreign particles may also be picked out of the residue with a pair of tweezers, ground finely and identified by chemical analysis. The residue from the sieving will also contain particles of flint from the tube-mill pebbles, if these have been used to grind the cement, or splinters of iron, if Griffin mills are used. Neither of these can, of course, be considered as adulterants and both can readily be identified; the former by the fact that even when finely ground it is insoluble in hydrochloric acid, and the latter by its magnetic properties.—The Chemical Engineer.

Unusual Shaft Sinking.

In a paper contributed to the Institution of Mining & Metallurgy, London, Edgar A. Collins, the manager of the Combination mine, at Goldfield, Nevada, gives interesting details concerning the sinking of a shaft on an extraordinarily rich body of gold ore. Mr. Collins says that the ore-shoots of the Combination mine are typical of the district. They are closely associated with the irregular masses of shattered and silicified quartz andesite or dacite, which have intruded through the decomposed porphyritic country rock, an altered andesite.

The rich ore seems to follow the lines of greatest fissuring. The rich ore usually occurs either in irregular seams traversing the silicified mass in a direction roughly parallel to its greatest dimension or else in the form of small lenses and bunches. The contents are usually soft iron-stained kaolin, with shattered and brecciated quartz and irregular fragments of dacite. The richest mineral is usually in the kaolin, in the oxidized zone; in consequence it can be concentrated to a large extent by screening over an ordinary fine grizzly.

The shaft was sunk with the idea of prospecting a small bunch of exceedingly rich ore which was found on the surface, by trenching across the outcrop. At the point of discovery this bunch did not appear more than three or four feet long, but after sinking a few feet the pay-streak showed itself to continue for the full length of the shaft, varying in thickness from six to 18 inches.

In order to keep the ore as high grade as possible, the rich streak was taken out first, and kept fairly clean from the low-grade rock on either side. The latter was then broken by itself and sent to the mill bins. As sinking progressed, it was seen that the very rich ore occurred in small bunches of irregular shape. Between them the silicified dacite would sometimes be blocky, and in such cases very poor, or it would be traversed by innumerable little stringers of a soft heavily iron-stained decomposed stuff, in which case the ore would vary between the two extremes. As a result of this, samples taken from each end, and three feet apart, would vary enormously, one sample assaying, say, $10, while the next would assay as high as $1,500.

While sinking was progressing in this prospect shaft, the 130-ft. level from the main workings of the mine was extended toward it, the vein being finally cut within a couple of feet of where it was expected. This showed an unusual regularity in dip, as compared with other rich streaks of ore found in the mine.

At this depth (128 ft. vertical) the vein was quite different in appearance. Instead of being entirely within the silicified dacite, the ore was found just beyond but closely following it in dip and strike. The characteristic yellow-stained brecciated quartz was replaced by yellow-stained decomposed porphyry, with unusually coarse crystals of kaolinized feldspar, and blotches of almost pure iron-stained kaolin. Both the decomposed porphyry and the kaolin assayed high, but the last-named was far the richer.

Between this material and the country rock, and separating the bunches of rich kaolin, the vein-stuff consisted of highly silicified dacite and quartz, which however, was almost valueless. As a result of this, practically all the rich stuff became fine when blasted. By running the broken ore over a grizzly with bars set ¾ in. apart, and with the space under the grizzly divided into two bins, by a transverse partition about half way up, three different products were obtained, namely: (1) Very rich fine; (2) Low-grade coarse; (3) Intermediate size, of intermediate value.

This shaft was in ore for its full depth. Between the zone of greatest enrichment (in this case the first 70 ft.) and the rich ore found immediately above the 130-ft. level (say 30 ft. above the track) there was a poorer zone, composed of less shattered dacite, in which practically all the rich ore was contained in thin seams, in every direction.

The total value and tonnage of the ore extracted from the surface croppings down to the back of the 130-ft. level, a distance of about 122 ft., was approximately 309 tons, valued at $159,000. This was distributed as follows:

	Tons.	Average Assay Value Oz.
Shipped to smelter direct	103.0	42.6
Treated in mill and then shipped	58.7	54.8
Sent to various stock piles	147.8	2.3

The above figures refer to gold alone, the silver content being insignificant, the ore averaging only one ounce silver for each 20 oz. gold.

Additional development work brings to light the fact that this extraordinary shoot of ore is almost insignificant in length, so that it may be likened to a pipe, with the shaft in the center.

Iron Mining on a Big Scale.

All signs indicate that this is to be a record-breaking year among the steel-makers. Railroads are ordering thousands of tons for use in extensions and the re-laying of existing tracks. Forty-two thousand tons are needed for one of New York's bridges. Elsewhere bridge-building and rising skyscrapers in scores of cities help to swell the demand. And in addition, steel must be supplied for the re-building of San Francisco. This activity in the steel trade means that there will be even busier times than usual on the ranges north of Duluth where material for skyscrapers and bridges is dug from the earth. From these deposits comes the bulk of the high-grade iron ore used in the steel-making industry. Last year there were shipped from the Duluth customs district 21,830,885 tons of what to the uninitiated looks like a reddish brown gravel mixed with pebbles and small stones of the same color. This is the ore which has made the Mesabi and Vermilion ranges famous among miners and iron-workers the world over.

The visitor to the Minnesota ore fields is likely to have his ideas of mining methods suddenly altered. He has thought of a mine, perhaps, a shaft leading down to galleries far beneath the surface of the earth. There are such mines in this region, but its distinctive feature is open-pit work. An open-pit mine is well described by its name. It is a hole in the ground and some of these cavities dug in the face of the landscape are so large that they resemble craters of great extinct volcanoes.

Take the Mountain Iron mine, for instance, from which, in 1905, 2,495,089 tons of ore were shipped. It is so deep and so long that a string of railway cars seen at a distant point in its depths looks no bigger than a toy train with which a child plays upon the nursery floor. This artificial valley is more than half a mile in length and its average breadth exceeds a quarter of a mile. There is a point where from the grass-roots to the bottom of the pit the distance is 225 ft. and the average depth is 150 ft. Ore has been shipped from the Mountain Iron mine for only 14 years, although it is one of the oldest on the Mesabi range, yet in that time a total amount exceeding 12,000,000 tons has been sent away to be converted into the steel on which run the trains of great American railway systems and which forms the frames of towering skyscrapers and mammoth bridges. Last year on the Mesabi and Vermilion ranges ore was taken from 71 mines, ranging in size from that which produced less than 1,000 tons to the eight which sent out over 1,000,000 tons each.

The mines are scattered in groups. Here and there rise, tall and gaunt, the shaft-houses of the underground workings. There is everywhere a tangle of railway tracks, running from mine to mine and down into the pits. It sounds like a continuous Fourth of July celebration, for rock and ledge must be blasted away when they obstruct the work and the reports of dynamite charges boom like giant cannon crackers. Nothing is allowed to interfere with the mining operations. Land is sold here with the ore rights reserved and in at least one instance an entire town has been moved bodily out of the way. This happened to Eveleth, a town of several thousand people. The streets were lighted by electricity and the place had its sewer system and public water-works. But Eveleth stood over a deposit of valuable ore and so it was rebuilt at a point on a hillside some distance away from which it now looks down on the mine workings that mark its former site.

Mining on this mammoth scale has brought prosperity to the range towns. Brick business blocks stand in the midst of the houses of the mine workers and, as it is still a new country, log cabins are sometimes found in the shadow of hundred thousand dollar schoolhouses. Three railroads extend from the mines to Duluth and they are busy lines.

During the eight months of the year, when navigation is open on the Lakes and the mines on the ranges are working full blast, the man who stands at the edge of one of the great ragged holes torn in the ground by the energy of giant steam-shovels, some of which lift six tons at every stroke, sees far below on the railroad tracks, which seem to roam in hit-or-miss fashion through the pit, long lines of ore-cars drawn by locomotives as large as those which haul the freight trains on many railroads. Such a train comes to a standstill by the side of one of the steam-shovels. With a few movements of its mighty arm, the shovel fills a car which holds from 35 to 50 tons of ore. As car after car is filled, the train is moved along jog by jog, and when the work of loading is completed it is hauled up the incline from the pit to the surface of the ground. There at the edge of the mine it is turned over to one of the ore-carrying roads and sent away on its journey to the shores of Lake Superior.

For transferring the ore to vessels, great docks have been erected. These ore docks are unlike any other type of cargo-handling appliances in the world. They rise 60 to 70 ft. above the water and some of them are half a mile long. At the top are the railway tracks, on which are run the ore-laden cars. Their contents fall into huge pockets, and thence, through chutes, to the holds of the waiting vessels. All told, the docks of Duluth and its associated ports from which shipments of last year were made, have a capacity of 681,440 tons and a water frontage of something more than seven miles, and additional docks are now being completed. To carry the ore eastward last year it required 892 vessels, more than three times as many as the craft of all classes now fit for service in the United States navy, and this great lake fleet transported 3,807 cargoes.

From the time operation begins in the spring until navigation closes, work in the open-pit mines goes on with few interruptions. At night electric lights flare in the depth of the excavations, and always there is the rumble of long trains and the clanking of the chains and creaking of the machinery of the great shovels.

All of the digging done by the steam shovels does not bring out ore, for before the precious reddish brown material is reached, the earth must be removed or, as the mine men say, the stripping must be done. There are places where the ore is found only a few feet below the surface; in others, the rock and earth must be taken out to a depth of 75 ft. before the ore is reached. This earth is hauled away in cars to places where tests have shown that no ore is likely to be found. There it is dumped in great piles. Near the town of Hibbing on the Mesabi range, one of these dumps, which looks like an artificial hill a hundred feet or more in height, has been selected as a house lot by a man who apparently wants to live in a place with a good outlook of the surrounding country.

While in the open-pit mines business goes on only during the navigation season, the underground mines work the year round, during the winter piling the ore at the mouth of the pits so that in the spring there are scattered about the landscape red-colored hills which during the summer disappear and are loaded by the steam-shovels. The underground workings are sometimes conducted in connection with open pits, becoming in that case what are known as milling propositions, the ore dug in the pit being hauled through tunnels into the old workings and raised to the surface through the shafts.

These ranges, which have made Duluth the greatest ore-shipping city in the world, are places where there is little use for the man with the pick and shovel. It is a region where vast results are obtained by the use of great power. Up to the present time these operations have been dependent upon the energy of steam. Now, however, with the completion of the great hydraulic development near Duluth, which, combined with electrical transmission, will supply power to all the region roundabout, it is likely that electricity will do much of the work on the ranges, in addition to running trolley cars, lighting streets and supplying power for many purposes in Duluth and other cities.

While the output of the mines will increase rather than diminish as the years go by, the men who are digging iron ore on the Mesabi and Vermilion ranges are at present setting a pace which, if it could be followed by the canal builders on the Isthmus of Panama, would join the Atlantic and Pacific in a shorter time than has been estimated as needed for the undertaking. The 21,000,000 tons of ore which constituted last year's shipments from the Duluth district would make about 11,000,000 cubic yards. When the majority of the engineering board reported that to build a sea-level canal across the Isthmus of Panama, a task requiring the removal of 110,000,000 cubic yards of material would take ten years the minority of the board declared that the excavations would not be made in less than 15 years. Yet the work could be done in the shorter time if the material were taken out as rapidly as the iron ore is dug from the earth on the range north of this city. The output of the Mountain Iron mine last year exceeded by 400,000 cubic yards the amount of excavation done in 1905 in the Culebra Cut. If the ditch diggers on the Isthmus excavated as rapidly as do the miners on these ranges, the lock canal which is favored by the majority of the board of commissioners could be excavated in five years instead of the seven and a half years estimated.*

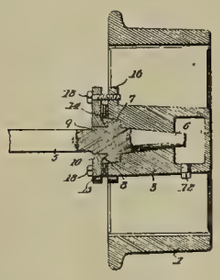
*From the Mining Gazette, Houghton.

Mining and Metallurgical Patents.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

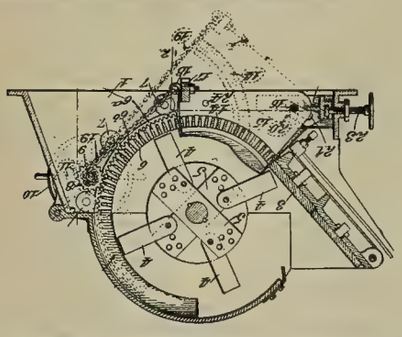
MINE-CAR WHEEL, No. 818,108. J. J. McCully, Mexico, Mo.

The combination with a mine-car wheel, of a spindle having a collar provided on its outer face with an approximately V-shaped circumferential seat, a dust-guard having a flange corresponding to the shape of the seat and fitting therein, washers interposed between the dust-guard and the wheel-hub, and means for assembling the guard with the wheel.



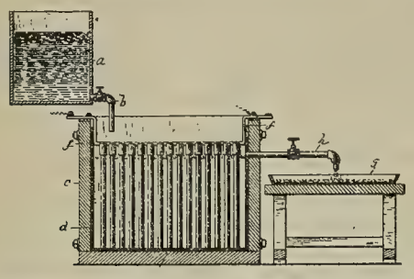
TUBULAR BALL-MILL, No. 818,211. M. F. Abbe, New York. N. Y.

A tubular ball-mill composed of a rotatable cylinder, inclosed pebbles, a power-shaft, means for suspending the cylinder from shaft, a sustaining-shaft journaled sidewise from the cylinder, and means for rotatably connecting the cylinder to the sustaining-shaft.



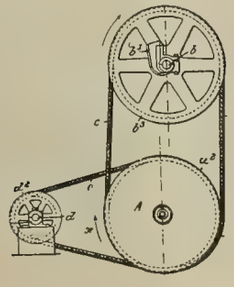
PROCESS OF RECLAIMING WASTE GOLD AND OTHER VALUABLE METALS FROM WATER AND OTHER LIQUIDS, No. 818,174. C. E. Holland, New York, N. Y.

The process of reclaiming gold or other precious or valuable metals from water or other liquids, consisting in conducting the stream or body of liquid to an electrolytic apparatus, subjecting it to electrolysis, in the presence of a body capable of forming a coagulum, and collecting the coagulum produced thereby.



DUMPING-GAGE FOR CRUSHERS AND PULVERIZERS, No. 818,725. M. F. Williams, St. Louis, Mo.

In a machine of the character described, the combination with a grinding-surface composed of sections, one of which is pivotally mounted, means for adjusting the pivotal support for section, means for swinging section on its pivot, means being also operatively connected to other sections to move the same.

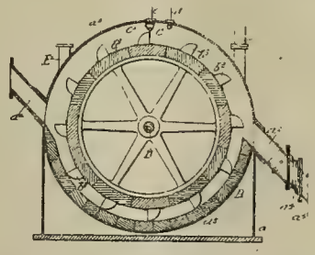


HAMMER-DRILL, No. 818,638. W. Prellwitz, Phillipsburg, N. J.

In a hammer-drill, a hammer-cylinder, its tail-rod and a protective casing having its walls entirely spaced from the cylinder, the cylinder and tail-rod having sliding engagements with and supported only by the ends of the casing for the purpose set forth.

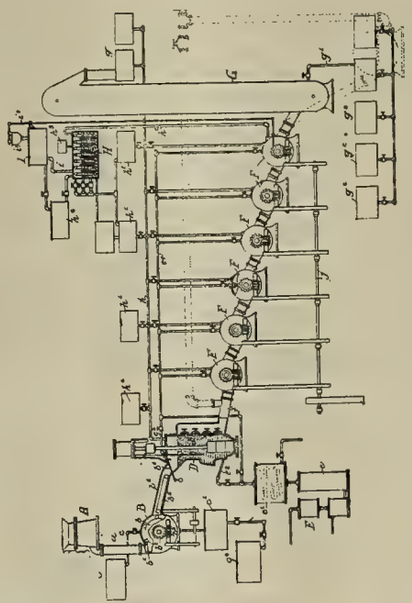
LIXIVIATOR, No. 820,812. Sidney T. Muffly, Philadelphia, Pa.

A lixiviator consisting of a containing-receptacle having an inlet and an outlet, a revoluble structure within the receptacle having pulp-carrying means, with a wooden lining within the lower portion of said receptacle.



PROCESS OF EXTRACTING PRECIOUS METALS FROM THEIR ORES, No. 820,810. Sidney T. Muffly, Philadelphia, Pa.

The process of treating ores which consists in pulverizing said ores while they are immersed in a solution capable of dissolving the contained gold and silver, said solution being exposed to air under pressure greater than that of the atmosphere.

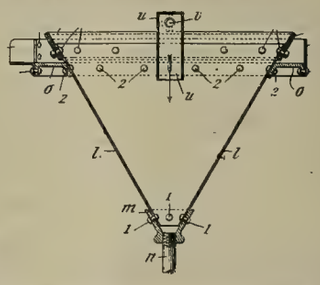


BLASTING-POWDER, No. 820,854. B. Eberle, Passaic, N. J.

A blasting compound consisting of four pounds saltpeter, one and one-half pounds chlorate of potash, one and one-half pounds of sugar, three ounces of phosphorus, three-fourths pound sulphur, and one-half pound manure.

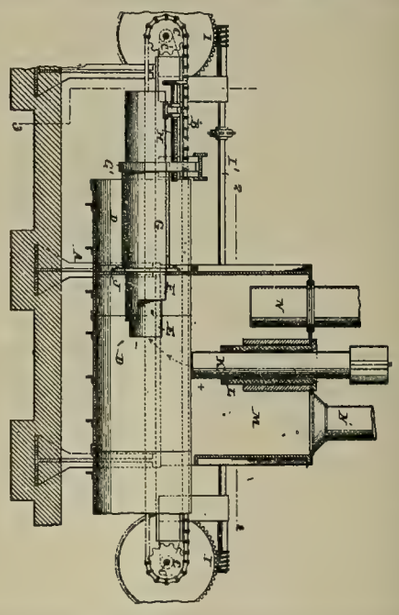
CLASSIFIER, No. 820,934. Charles W. Merrill, Lead, S. D.

A classifier provided with an overflow-line of soft metal extending around its entire periphery.



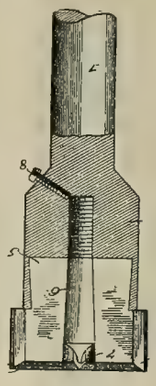
ELECTRIC FURNACE, No. 820,574. James E. Hewes, Plattsburg, N. Y.

In an electric furnace, the combination of a trough-like hearth for the materials to be smelted having side flanges, two electrodes arranged at an angle to each other one of said electrodes being in alinement with the length of the trough-like hearth, two side guides B' on each side of the hearth, endless traveling chains or conveyers B B traveling over and resting above said guides and directly supporting the flanges of the hearth.



ROCK-DRILL, No. 820,530. William Sturm, Chicago, Ill.

A rock-drill comprising a shank, a plurality of removable cutters arranged on opposite sides of the center of the drill said cutters being provided with peripheral cutting edges, and a central locking device for locking said cutters in their sockets, said locking device being also provided with a cutting edge located between oppositely-disposed cutters.



PROCESS OF MANUFACTURING IRON DIRECT FROM ITS OXIDES, No. 820,898. James N. Whitman, Philadelphia, Pa.

The improvement in process of manufacturing iron direct from its ores, which consists in comminuting and mechanically purifying the ore, then subjecting the comminuted ore to heat under oxidizing conditions to eliminate volatile impurities, then subjecting the ore to heat and agitation under deoxidizing and carburizing conditions produced by the introduction of free carbon, to partially deoxidize, partially reduce and agglomerate the ore into coherent masses.

Special Correspondence.

JOHANNESBURG, May 7.

All classes of the community are excited over the arbitrary action of the Home Government in regard to the repatriation of the Chinese. During the last political campaign in England, the Liberal Party, then out of office and thirsting to get in, used the cry of "Chinese slavery on the Rand" for all it was worth. No lie was too mean for them, no trick too contemptible. The Liberals got in, and people here thought that as they had gained their object, they would drop the Chinese question. But they have pestered us ever since their accession to power. Things have come to a critical point. The Home Government insists on posting notices in the compounds, telling the coolies that they can return to China at the expense of the Government, if they show good reasons.

Was ever anything more unjustifiable? Did ever Government make a move so fraught with disaster? Here is an ordinance, duly agreed to by the King and the Emperor of China, by means of which coolie labor is to be supplied to the Rand. The Chinamen have entered into a three years' agreement with the mines. The Liberal Government steps in, utterly disregarding the legislation of their predecessors in office, and interferes in a private contract between the coolies and the mining companies. By the repatriation of all the Chinese the majority of the people of the Rand would suffer, some irreparably. Even the departure of one-fourth of the coolies would cause great distress. There are not sufficient Kaffirs to work the mines, and many of them would be forced to close down if the Chinese went. It is becoming more and more difficult to get Kaffir labor. It requires little to make the native a well-to-do man, and in Zululand, Zwazieland and Basutoland, the blacks are fast becoming independent. The great inducement for coming to the Rand, which once existed, namely to earn money to buy whiskey, no longer exists, as the Government has almost entirely stamped out the liquor traffic among Kaffirs. It has been proved that under present economic conditions, it would be impossible to employ white labor solely, save on a few high-grade mines of the Central Rand. If the Home Government is desirous of closing down the mines, the surest way to do it is to make an offer of repatriation to the coolies.

Seeing the disastrous nature of the proposals, it is not to be wondered that meetings of protest have been held here. What everyone asks is, "How many coolies will take advantage of the offer?" Needless to say people here will use every legitimate means to defeat the proposals of the Government. It is probable that the mines will out-maneuver the authorities, and that only a few coolies will go back to China. The indignation is over the principle of the thing.

The mining companies have taken up a bellicose attitude, and have written to the Government refusing to post the notices in the compounds, on the ground that the notices are illegal. How the Government will retaliate is not known. Force might be used to post the notices and keep them up. Altogether it is a red hot situation, and developments should be distinctly interesting.

LONDON, May 23.

Judging from the flowery periods in the county press and the warmth of the debates amongst the old hands at the Cornish mine meetings on the subject of 'cost book' versus 'limited liability,' the unthinking uitlander might be tempted to the conclusion that the unaccustomed shouting of prices on the Redruth Exchange had engendered a thirst which caused more than the usually moderate libations to be poured forth at the local shrines in honor of the leading favorites. It seems true that numerous and quite reckless bargains for the rise have been made in the home markets lately, and the 'adventurer' in the sweet West country may be pardoned, amidst such scenes of new-born enthusiasm, if he imagines that the excitement has also stirred the too stagnant waters of the London mining market. But for the present the list of successful tin mines is too meager to create a ferment in that center. There are not enough shares to go round. This could easily be gathered from the best list that can be produced of the active mines, nine in number. Here it is:

	Capital.	Price per Share. Beginning of 1906.	May 18.
Limited Liability—			
Basset Mines	£120,000	3s. 6d.	10s.
Clitters United	160,000	17s. 6d.	21s. 6d.
Carn Brea & Tincroft	150,000	6s.	9s. 9d.
Dolcoath	350,000	12s. 9d.	26s. 3d.
Cost Book—			
East Pool	6,400 Shares	£2⅜	£10¾
Levant	2,500 " (or less)	8¾	15¾
South Crofty	6,120 "	1	2¼
West Kitty	6,000 "	2⅝	6¼
Wheal Grenville	6,000 "	9	12 x. d.

London, although calm, is not unobservant of Cornwall's possibilities, and it may be taken for granted that with the continuance of anything like the present price of tin, the list of producing mines on the limited liability principle, will be found to increase. Some solid progress toward this end has already been made, as readers of this correspondence are aware. It will, however, be a matter of time before the great financial groups can be convinced that there is sufficient scope for their energies in re-opening the partially worked abandoned mines. Virgin ground must be prospected and proved by other means, for the promoter in these days prefers to buy ore reserves which he can turn over to a company at a profit. On the other hand it is not all smooth sailing for the "honest broker." The 'lords' dues' take some of the sugar off the cake to start with; one-fifth of the profits is not considered excessive. According to well-informed opinion a trouble in front of Cornish mines will be what it is in South Africa—the want of labor. The supply is not considered too great at the present time, and it is feared that it will be less plentiful when the numerous other mines are set to work, which are now being talked about. Most of those employed in the mines at the present time are said to be the young men and the men advanced in life. Those of middle age are abroad, working in all parts of the world, but chiefly in Africa. There is so much activity in Cornwall now that a good many of these men are returning, but it is scarcely likely that, having received the scale of wages common in South Africa, they will resign themselves to the comparatively low rates of pay that rule in Cornwall. The mines must be prepared in the near future to pay somewhat higher wages than they have been in the habit of doing.

In view of this, mine managers are exerting themselves to do away with hand labor as far as possible. The rise in wages, should it come, will thus in large measure be compensated by improved appliances, which are now to be seen in the leading mines in the county. In tin-dressing alone it is said there has in this way been an enormous economy of labor.

It is thought the 'cost book' system is to all intents and purposes dead. Such seems to have been the opinion of Wheal Grenville 'adventurers' at their meeting last week when a lively wake was held around the corpse. One of the old hands, a large shareholder who spoke strongly against 'limited liability,' in addressing the chairman said it was a question if some of his colleagues could tell a working-barrel from a poppet-head. He knew others on the board who had not joined because of the paltry remuneration they received, and he firmly believed that they could develop its mineral resources for the interests of the shareholders; but still he could take some of their co-directors and ask them what is a poppet-head, and what is a working-barrel, and they could not tell him.

As an indication of the local feeling against the adoption of 'limited liability,' when the resolution in its favor was put to the meeting 22 voted for it and 24 against, but a poll was taken which by counting the proxies, resulted in a large majority of votes for the resolution. In the course of discussion the Company's legal adviser, Mr. C. V. Thomas, explained the disadvantages of the 'cost book' system. He said: "Eleven years ago I had the honor of being asked to consider whether or not it was possible to convert a cost book into a limited liability company, for that was a position very much controverted and bid fair to be fought out; but after obtaining the best advice I could, a plan was evolved for Dolcoath whereby we could convert a cost book into a company with limited liability. The lines I had the honor of laying down in that case were found to be successful, and have never been challenged since. I carried them out also in Carn Brea and Tincroft, Killifreth and Basset, so that the steps we think necessary to take in this case are very clearly defined and present in themselves no difficulty. There is no method known whereby a cost-book company can sell its undertaking except by public auction, and that only under the laws of the Stannaries Courts. It is a cumbersome kind of machinery admirably suited for a few friends who can rely upon each other, and between whom the ties of honor and friendship are strong. But when a cost-book company is on a basis other than this, then it is the worst devised system in mines, for no one at a given moment can know who his partners may be or what his liabilities are." The remarks on the same subject by one of the directors are also worth quoting: "I like the cost-book system, and any merchant ought to like it. He is safe, but there are drawbacks. In shallow mining the cost-book system was very well, particularly when the partners knew each other, but would you put your money into a foreign mine on the cost-book system, not knowing who your partners were? If not, then how can you expect outsiders to come here on similar terms? There was a mine near here and we asked the shareholders to submit to a call to carry out certain work. We had to face relinquishments, and speedily the 6,000 shares became 3,000 and the mine had to be abandoned, or the attempt made to float it as a limited company."

Mr. C. Algernon Moreing, who has been on a visit to Broken Hill, when referring to the future of that district, is reported to have stated that Broken Hill has entered upon a stage of prosperity which has never been equaled in its past history; and this has been brought about by the development of numerous processes for the recovery of the zinc in addition to the lead and silver. By the operations of the Zinc Corporation, practically new zinc mines have been created out of what were formerly only waste products. The value of the field has been probably doubled, and its permanence for a great number of years assured. He was highly pleased with the outlook of the Zinc Corporation. Although the company has been only six months in existence, it is already producing marketable produce, and is selling the same to Germany on a profitable basis. With regard to the South Blocks mine, he had been struck by the rapidity in which the opening of the mine and the installation of the plant are taking place. He could safely say that this mine will rank with many of the present big mines in a shorter time than many people anticipate. The Australian Smelting Corporation will be an immense advantage to all those Broken Hill mines which do not own their smelters. He hoped the smelting company would be doing business by the end of this year.

The following returns have been announced from Mexican mines:

Dolores, March; bullion account, $26,403.70; sundry receipts, $133.53; expenses for month, $14,618.38; profit for month, $11,918.85, representing the return from amalgamation alone, as the cyanide plant is not yet complete. Ore crushed: Mill, 781 tons. Value recovered by amalgamation alone, $33.98 per ton. Owing to lack of mine-cars and other supplies there was a shortage of ore sent to, and treated at, the mill during the month.

Esperanza, April; The mill ran 30 days and crushed 12,561 tons of dry ore. Shipped to smelter, 3,844 tons of dry ore, estimated realizable value of bullion produced, $136,767; of concentrate, $74,817; of ore shipped to smelter, $282,484; receipts from rents and other sources, $519; total, $494,587. Less working expenses, including development, marketing of bullion and freight and treatment charges on ore shipped to smelter, $212,936; allowance for depreciation of plant, $2,500; consulting engineers' fees and New York office expenses, $2,567. London expenses about £250; estimated profit, £56,427. Of this there has been expended on construction account, $5,179, or £1,061, and prospecting on Suceso property, $4,088 or £838. Feet of development work, 909. The shortage of railway cars still continues.

El Oro, April; The No. 1 and No. 2 100-stamp mills each ran 29 days, and together crushed 22,186 tons of ore, producing $192,599, less working expenses, $89,655; development expenses, $8,742, making $94,202. Profit from the railway for the month, $3,000. Total, $97,202 or £19,440, less estimated monthly expenses in London, and manager's salary, £700; leaving a profit for the month of £18,740. The sum of $20,308 was expended during the month on permanent improvements.

DENVER, June 4.

It is too bad that so much mining energy, brains and money has to be dissipated in law-suits. Just now the Clipper Mining Co. and the Searle Placer people are fighting it out in Leadville. Each side has 27 witnesses, that is 54 men. Each side has three attorneys, that makes 60. Then there are the parties interested, about four to the side, that makes 68. Say the average time spent on the case is ten days, that makes 680 shifts of work—680 shifts of work diverted from enriching the world by increasing its mineral output and devoted to impeding the procession and stirring up a cloud of dust. Look at it another way: I suppose each side will spend $40,000 to $50,000 on this suit, say $90,000 all told. How many prospects there are which $90,000 would convert into profitable mines that are lying idle for the lack of the equipment such a sum would provide. And what is it all about? In a nutshell, it is all caused by our poor mining laws. In 1877 Tom Starr located the ground since called the Searle Placer. Starr took it up as an addition to the City of Leadville, just as the townsites of Goldfield, Bullfrog and other new townsites have been taken up, except that he took it up as a placer claim. Now the way I understand the law he could not have taken this ground up legally in any way at all. It is in a mineral district, so he could not take it up as agricultural ground. There is no alluvial gold in it, so a placer location is not valid. To comply with the lode-location laws, he would have had to sink 250 ft. through wash and 250 ft. through lacustrine deposits in 60 days; quite a herculean task! Then he might not have found "mineral in place" even under

the liberal interpretations of our Colorado courts. Well, anyway, he located a placer; but he or his assigns were foolish enough not to keep peace with their neighbors and get a patent right away, so that when finally they did apply in 1881 they tried to sneak a lot of Freyer Hill, including the following mining claims, the Zulu, Bob Ingersoll, American Eagle, Grafton, Esmall, and Fairview. Naturally, the enterprise got into hot water and in 1882 an amended application was made, omitting a large part of the territory covered by the above-mentioned claims. But still there were objectors, and the Government sent Robert Berry out as special agent to investigate. On his report the Registrar and Receiver of the land office cancelled the application for patent on the grounds that the placer was located in fraud and the annual assessment work had not been kept up. But, and here lies the trouble (springing from the complexity of our laws), the land office did not cancel the location certificate when it canceled the application for patent. Since then the ground has been proved immensely valuable for lode mining purposes and in the 'eighties the Clipper Gold Mining Co. located four lode-claims on the discredited placer. In 1893 the Clipper Gold Mining Co. applied for patent and the Searle Placer was allowed to adverse them. The Searle Placer had already been declared a fraud and not entitled to a patent, yet it was given sufficient standing in court to adverse these lode-claims. The present hearing has finally resulted from the application for patent in 1893 of the Clipper Gold Mining Co. on the claims Capital, Clipper, Congress, and Castle.

The facts developed during the trial are briefly these: There is some gold in the gravel, but nowhere near enough to justify placer-mining operations. The expert testimony has been singularly consistent on both sides. Max Boehmer and Prof. Young are among the prominent expert witnesses on the placer side of the question, while Governor McDonald and Judge Owers turned up as partial owners in the Searle Placer; and Judge Owers aroused considerable interest by trying to explain certain judicial actions which he has taken in the matter at the time he was a part owner. Prof. George of the State University, Regis Chauvenet and George J. Bancroft are among the expert witnesses for the Clipper Gold Mining Co., and J. W. Finch is also expected to testify. Prof George's testimony regarding the glacial epoch in Colorado is probably as exhaustive a study of the question as has ever been made public and, regardless of the law-suit which evoked it, is a valuable addition to the sum total of human knowledge

The contention of the lode-mining people is that the gravel is glacial moraine and of the placer people that it is river gravel. However that may be, there has never been any serious attempt to work the gravels of Poverty Flats, on which the Searle Placer is located so the ordinary observer will pretty safely conclude that the ground is worthless as a location for mining alluvial gold. All the complexity of the United States mining laws as brought out in this case will serve as a very powerful argument, no matter which way the case is decided, for a complete revision of these laws. For instance, why should our agricultural industry have laws (governing the acquisition of government land) which evoke practically no law-suits, while our mining industry struggles along under such a heavy burden of litigation. The American Mining Congress has taken a step in the right direction, but the whole mining public must lend a helping hand if anything is to be done.

SALT LAKE, June 4.

The first shipment of concentrate from the Godiva mill, in Tintic district, has reached the Salt Lake smelters, and it is announced that the capacity of the plant will be increased by the addition of more tables. Jackson McChrystal, of Eureka, is manager.——The necessity for repairs at the Bullion-Beck mine of Tintic has caused a shut-down for a few days.——Ore from the Victoria mine is now being extracted through the 800 and 900-levels of the Grand Central mine near Eureka. ——The concrete foundation for the new hoisting engine of the Star Consolidated mine, at Eureka, has been finished.——A tunnel is being driven on the property of the Prairie Bell Mining Co. in West Tintic district.—— The Uncle Sam Consolidated management has contributed a car of ore to the School of Mines department of the State university for experimental purposes.

The Galena King Mining Co., at Stockton, will probably resume shipments soon. The mine has been idle for some time, awaiting the advantage of the Honerine drain tunnel.——The New Stockton Co., at Stockton, has reached a depth of 1,027 ft. with its shaft. It is the intention to develop the mine at this level before going deeper. J. J. Trenam, manager, says the output of the mine will be doubled within 60 days. The mill is running two shifts of eight hours each. A 10-ft. vein of lead ore, mostly of shipping grade, has been encountered in the Honerine drain tunnel, at Stockton. A drift has been run on it over 30 feet.

The Bingham Consolidated and Cluster Mining Co. have settled a dispute over apex rights to a claim in conflict. A proposition made by the management of the Bingham Consolidated, to ascertain the facts, at its own expense, by further development, was accepted by the Cluster management.——The Utah Apex Mining Co. is preparing to install a compressor at its Bingham mine. ——The Ohio copper mine, in Bingham, is being examined by A. Frank, of the staff of F. A. Heinze, supposedly for the Bingham Consolidated Mining Co. which has large interests in Bingham.——Track-laying has begun on the Rio Grande railroad extension over which the ore of the Boston Consolidated and other Bingham mines will be transported.——The directors of the Utah Apex Mining Co., operating in Bingham, have authorized the issue of $500,000 worth of 10-year bonds, bearing interest at five per cent, convertible into stock of the company at par—$5 per share, prior to January 1, 1907. A special meeting of shareholders has been called for the 28th inst. to ratify this action. It is said only $100,000 of these bonds will be issued now, the proceeds to be used in the purchase of an air compressor and other equipment, in the construction of an aerial tramway, and for the purpose of further development.

Connections have been made with the orebodies on the 300-level below the tunnel in the Columbus Consolidated mine at Alta. The company has 42 four-horse teams hauling ore. The management expects to realize $100,000 on the June shipments. It is believed the company will pay its initial dividend in July.——W. S. Zehring, in behalf of the interests identified with the management of the City Rock mine, at Alta, has secured a bond on the St. Louis-Alta group, an adjoining property.

Development work has begun on the Blue Bird property, near Milford, Beaver county, recently bonded to James F. Burns of Cripple Creek. It is said Mr. Burns has an option on the Indian Queen mine, near the Newhouse Cactus property in the same county.——The Imperial Copper mine in Beaver county is to resume; at least, that is the statement made by A. B. Lewis, president of the company. The Consolidated Mercur mine, of Mercur, handled through its mill in May the usual amount of ore—25,000 tons.

Development has been resumed at the Mt. Masonic mine at Park City, after a shut-down of several weeks. This mine is owned by Iowa capitalists.——The Daly-Judge Mining Co. has begun stoping the big orebody opened during the past few months on the 1,500-ft. level. The management expects to have all its obligations cleared up by July 1. The earnings are about $50,000 monthly at present.——The shareholders of the Woodside Mining Co. have ratified the sale of the property of that corporation, by the board of directors, to the Silver King Mining Co. at Park City. The raising of structural steel for the Utah Copper Co.'s new concentrator, at Garfield, has begun.——Much interest is being manifested in the Deep Creek mining district on the western border of the State, by Salt Lake mining men. Numerous properties have been bonded recently and indications point to increased activities in that section upon the building of the Western Pacific railroad westward from Salt Lake City——An important strike is reported made last week in the property of the Nevada Gold Butte Mines Co. at Gold Butte, Nevada. The company is developing its mine by means of a tunnel and a compressor plant is being considered. L. A. Copeland of Salt Lake is president.

SALT LAKE, May 31.

The No-You-Don't group, at Stockton, has been bonded to H. E. Smith of Duluth, who will organize a company to develop it.

The Columbus Consolidated, which has been shipping ore steadily for some time, on the advent of good roads, will increase its output.

The Honerine mill, at Stockton, is in operation, with one shift, at present. Later the force will be increased, both in mine and mill. Recent development in the mine indicates that the Honerine will soon become a shipper.

The management of the Ohio Copper Co. is making strenuous efforts to begin ore production at the Winnemuck, one of its Bingham properties. The underground workings are being re-timbered where necessary. The mine is said to contain a great deal of $25 ore.

Samuel Newhouse has returned to Salt Lake after having made an inspection of the Cherry Creek and other eastern Nevada districts, where he has secured options on several properties.

The directors of the Consolidated Mercur Gold Mines Co. have posted a quarterly dividend of $25,000 payable in July. The Sacramento Gold Mining Co., operating in the same camp, has also posted one of $5,000. The laying of the concrete foundations for the new Boston Consolidated mill, at Garfield, has begun.

E. W. Clark, of Ophir, manager of the Overland mine, at Sunshine, is authority for the statement that ore sufficient to keep the company's mill going for a long time has been exposed, but it will be several weeks before he will begin stoping.

At the recent annual election, the following officers were chosen to serve the Shawmut Consolidated Co., operating at Bingham, during the ensuing year: Leslie C. Weed, president; William Rotch, vice president; Robert A. Jackson, secretary and treasurer, all of Boston. A long tunnel is being driven to open the orebodies of the Cuba. The sixth MacDougall furnace at the Yampa smelter, at Bingham, is in operation.

The management of the Mammoth mine, in Tintic mining district, has decided to sink to the 2,260 level. ——Ore shipments from Tintic district last week aggregated 175 car loads, the shippers and amounts being: Ajax, 4; Black Jack 8; Bullion Beck, 9; Beck Tunnel, 7; Brooklyn, 1; Carisa, 4; Centennial Eureka, 53; Dragon Iron, 12; Eureka Hill, 5; Eagle & Blue Bell, 4; Grand Central, 4; Gemini, 4; Mammoth, 19; May Day, 5; Ridge & Valley, 3; Swansea, 1; Star Consolidated, 4; Uncle Sam Consolidated, 6; Victor Consolidated, 1; Yankee Consolidated, 6.

BUTTE, May 26.

The drift on the vein of the Raven at a depth of 1,500 ft. has been extended 300 ft., the vein varying from five to 25 ft. in width. The average return from the ore taken out in development is 4% copper, 6 oz. silver and $1 gold per ton. The same vein has been developed on the 1,200-ft. level, and on both levels chutes are being put in preparatory to stoping and shipping. The company has for some time been hoisting 100 tons per day, and within a few weeks the amount will be doubled. The Raven Co. owns two mines, the Snoozer and Raven.

The Kessler mine, owned by the Butte & St. Louis Mining Co., will be equipped with steam hoisting machinery, pumps, etc. As soon as the plant is installed the company will begin hoisting ore.

The Washoe smelter will be enlarged to treat from 500 to 900 more tons of ore daily. The output from other properties and companies in Butte is also gradually increasing, and the smelter capacity of the district is being taxed. Additional smelters will become necessary if any of the new companies become extensive producers.

Options on a large tract of land on the Big Hole river, 40 miles south of Butte, have recently been secured by agents supposed to represent J. A. Coram and the American Consolidated Copper Co. which he is organizing.

The Amalgamated and Butte Coalition people are engaged in making a division of the ground and orebodies that for years were in dispute between the Amalgamated and United Copper, the latter the predecessor in interest of Butte Coalition, and as soon as the agreement is reached and each side knows what it is entitled to, work will be resumed on the mines that have so long been closed by injunction, including the Nipper, Snohomish, Tramway, Michael Devitt, Berkeley and others.

James Brown, a Montana mining man, is reported to have struck it rich in Nevada, in the new Catlin district about 40 miles from Caliente, where he located a dozen of the best claims.

W. A. Clark has opened a copper vein on the 1,900-ft. level of his Original mine. It shows a width of 17 ft. all good ore, four feet of it assaying 42% copper. Above the 400-ft. point the Original was a poor producer, but today it is one of the prominent mines in the district. The Original lies just west of the Parrot, and the latter adjoins the Anaconda.

The Parrot Mining Co. has decided to sink the shaft on the Parrot mine 600 ft. deeper. Work on it has been started. The shaft is now 1,800 ft. deep, and an additional 400 ft. will take it to the same depth as the workings of the Anaconda at the 2,400-ft. level, the collar of the Anaconda shaft being 200 ft. higher than that of the Parrot. The Parrot is at present hoisting less ore than at any time in its history.

The Amalgamated Co. is sinking three of its main shafts deeper. They are the High Ore, West Colusa and Parrot. The High Ore is being put down from 2,200 ft. to 2,400, and the West Colusa from 1,600 to 2,000 ft. The Boston & Montana is also sinking on the Greenleaf and has reached a depth of 280 ft. The same company intends to equip the Pennsylvania mine with a new hoisting engine. The one now in use has been doing duty for nearly 20 years, and is hoisting 1,000 tons of ore daily.

BUTTE, June 3.

From good authority comes the report that the Amalgamated Copper Co., or interests identified with that company, will purchase the Barnes-King gold mines at Kendall, Mont. Negotiations have been pending for some time and it is now understood that an option has been taken on the properties until next September, the price to be $1,500,000. A large amount of ore has been blocked out. The Barnes-King mines are considered one of the best cyaniding properties in the State. The principal owners are John F. Barnes, E. W. King and Joseph Underlin. It is expected that the new owners will enlarge the mill and increase the output of the mines. It is surmised that if the Amalgamated is the purchaser the Barnes-King company will be made one of the subsidiary companies of the Amalgamated, to be operated in connection with the holding company in the same way that its Butte copper companies are operated.

The Red Metal Mining Co., successor to the Heinze companies in Butte, is preparing to sink the shaft of the Corra mine 400 ft. deeper, the work to begin within a week. The shaft is now 1,800 ft. deep. A new hoisting engine, with capacity of working to a depth of 3,000 ft., was installed on the Corra by Heinze just before he sold out, and the surface plant is now in good shape for extensive exploration. After the 400 ft. of additional stoping ground is opened the shaft will be put down to 2,200 feet.

An interesting question is involved in a suit brought against the Washoe Copper Co. by the owner of some city lots and residence property over the Cambers mine workings, the action being one for damages on account of the sinking of the ground and cracking of the buildings due to the undergronnd workings. The case has been determined, so far as the district court is concerned, in favor of the Washoe Co., but the matter will be taken to the State and Federal Supreme Courts for the purpose of determining finally the relative rights of surface and mineral owners. The district court has decided that the surface of lots must be maintained in the natural and unbroken state, and that mining must be so conducted as not to interfere with the natural surface, but the support to be given the surface need not be sufficient also to sustain buildings on it. In other words, if the sinking and cracking is caused by the weight of the buildings and the ground would remain in its natural condition without the buildings on it, then the surface owner can not recover damages. If, however, the mining causes the ground to sink regardless of the weight of the buildings, then the surface owner can recover damages done both to the lots and the buildings. It is a question that has never been determined by the higher courts in Montana and is considered of great importance to both mining companies and owners of surface property, especially as a great deal of damage is constantly done to surface property by underground blasting and caving. Nearly the entire city of Butte is undermined, some of the biggest workings of the Amalgamated and Clark companies being directly under the business portion of the city.

The Reins Copper Co. is making rapid progress in its work on two cross-cuts from the 1,200-ft. point of the shaft, one being driven north and the other south. The former is supposed to be near the vein, as it is now in 80 ft. The exact position of the south vein is not known. There is a great flow of water in the cross-cuts, but so far, the company has been able to handle it with two pumps at the 1200-ft. station. It has been expected to strike the north vein within 80 ft., as on the 800-level it is but 40 ft. from the station.

The shaft on the Six O'Clock group, owned by the Butte Copper Exploration Co., has reached a depth of 625 ft. A station is being cut on the 600 while sinking continues. There is a flow of 100 gal. water per minute which the pumps readily control. Some stringers of ore apparently from near the walls of the vein, and pitching toward the shaft, have been cut, and the indications for striking an orebody appear to be good.

On the Greenleaf, adjoining the Six O'Clock mines, now being explored by the Boston & Montana Co., the shaft has reached a depth of 310 ft. From the 300 to the 1,000-ft. point the shaft will be three compartments, and later it will be enlarged from the 300 to the surface. The increased flow of water has made it necessary to make the shaft larger. At the 300 a water-saturated zone seems to have been tapped, for the water in a few minutes raised 40 ft. in the shaft, and the pumps for a time made little impression on it. The reservoir appears to have drained into the shaft, for in a few days the water decreased to the normal flow, which is about 250 gal. per minute.

The new hoisting engine of the Boston & Montana Co. at the Leonard mine is being placed in position. There will be eight new boilers of 250 h. p. each.—The machinery for the new engine and hoist of the East Butte Copper Co. has arrived at the Dutton mine and is being set up. The boilers are in position and the building has been erected over them. The surface work has not interfered with sinking, which has been continued with the old engine.——The shaft of the Butte & London Co. on the Greendale claim is now nearly 400 ft. deep. Work has begun on setting up the new hoisting engine. Four new boilers have also been received.

In the annual statement filed for record by the East Butte Copper Mining Co. it is stated that the company has no debts or liabilities, showing that its 134 acres of mineral ground has been fully paid for. It owns, according to the statement, the Dutton, Lassen, Hoy, Mary MacLane, Wheeler, Yankee Boy, Oneida, Jackson, Hancock and McDonald mines.——The Old Glory Mining Co. has taken up its option on certain interests in the Old Glory mining claim, the remaining interests being owned by the Butte Coalition Co. J. Benton Leggat, who organized the Old Glory, says he expects to resume work on the property soon, indicating that he has permission from the Butte Coalition to do so, as under Montana laws the owner of any interest in a mine can not operate the property without the consent of other owners. The Old Glory adjoins the mines of the Raven Co., and formerly the two companies worked in harmony through the same shaft, which they may now do again.

For many years a portion of the St. Lawrence mine has been on fire but the burning territory has been walled in and the fire prevented from spreading. As portions burn out and cool off they are opened and mined, large quantities of metallic copper reduced from the ore being found. The Anaconda Co. has been mining a portion of the burned ground and has been taking out slabs of solid metal. The fire has been burning since 1889, the sulphur supplying the fuel—a natural pyritic smelting process.

The Butte-Milwaukee Mining Co. has reached a depth of 60 ft. with the two-compartment shaft started on the Stonewall. The shaft is on a vein. Lessees have made one shipment of ore from the Pollock mine, one of the Butte-Milwaukee properties, that returned 15 oz. silver per ton, some gold and 2% copper. The property is well situated in the North Butte district and several of its mines were, years ago, big producers of silver. There is little doubt that the mines also contain copper.——The North Butte Co. has installed a large new compressor and the new hoisting engine will also be ready for use in a few weeks; the work of placing it in position is progressing rapidly.

DENVER, June 2.

The output of the Cripple Creek mines for May was 52,200 tons, an increase of 6,540 tons over April production. The published valuation of the May tonnage is $1,638,550.

A number of the old local reduction works that have been idle are expected to resume at an early date. Several of the new mills will also commence to treat ore in June, which will largely augment the yield of the district. It is reported that the Economic plant of the Woods Investment Company will soon pass into other hands and be operated to its full capacity. During the past month the plant has not been receiving ore for treatment. The mine operators confidently anticipate a larger increase in the output, although the average grade of the ore now being mined is lower than for past years.

Little hammer-drills are becoming very popular in the Cripple Creek district. Not only among lessees and for stoping narrow veins, but in mines operated by companies, they are supplanting the piston-drills to a large extent; mine managers who have had experience with the small drills claim that they will eventually supercede piston-drills for stoping. The dust caused by hollow steel and rosette bits has been almost eliminated by the use of solid steel for all back holes, so that now the little drills, properly constructed and operated, do not make as much dust as the piston type of drill in dry holes. There are several kinds of little hammer-drills in use in the district, and most of them will drill more linear feet of holes in any kind of rock than the 2 ft. 4 in. piston-drills, so that they fully make up in footage for what is sacrificed in diameter of hole.

The Shafter mine of Clear Creek county, which is credited with a production of about $1,000,000, has been developed at 300 ft. below the stoped ground by a lateral from the Central tunnel. At this depth an orebody, supposed to be a continuation of the surface shoot, has been uncovered over four feet in width, said to carry over three ounces of gold per ton.—— The Little Mattie group of mines, which has been operated under bond and lease for the past five years, has been transferred to the Little Mattie Mining, Milling & Power Company, of Idaho Springs. This group consists of 20 mining claims located on Chicago mountain.—— Recent development from the Headlight shaft of the American Sisters group of mines on Silver Creek, near Lawson, also in Clear Creek county, has disclosed two feet of ore valued at from $60 to $100 per ton. The mine is credited with a total production of $2,000,000, and has a dump estimated to contain half a million. A power plant for this property is being installed on Clear creek, to furnish power for machine-drills and a concentrator which is planned to treat the dump ore.

The unusual activity in Clear Creek county is spreading to Gilpin, and particularly in the northern part of the county, which is tapped by the Moffat road; old mines are being cleaned out and prospected, and new ones opened up. The old Perigo mine is being operated on the lease system and producing more ore than for a number of years past. The Bobtail mine of Central City is credited with a strike of ore on the 13th level, seven feet wide, assaying $75 per ton.

The Denver Chamber of Commerce is receiving numerous suggestions from disinterested (?) parties, as to "where a new mining camp may be found." In the majority of instances, a well-known and long-mined section is mentioned. The intention of the promoters of the 'new camp' idea is evidently to 'work over' old ground. It would be well to test some places where the existence of valuable minerals is not known. Why not send a geologist and an assayer, with portable outfit, at the head of each party?

TORONTO, May 28.

The members of the Ontario Legislature leave Toronto tonight on a four days' trip to the Cobalt mining camp and the mineral region to the north of it, as far as the rails are laid on the Temiskaming & Northern Ontario Railroad. Interest in the Cobalt region is kept up by continual reports of new strikes and discoveries, though latterly these have been mainly in connection with working mines. Prospecting for new locations in the Cobalt region proper is not nearly so active as last season, owing to so much of the territory being taken up, but the rush to the area farther north continues. The Temiskaming Mining Co., who are trenching a property known as the Dagle location near Cross Lake, have struck a silver-cobalt vein eight inches wide at a depth of five feet, a sample of which was found to assay 4,000 oz. per ton. This strike indicates that the Cross Lake formation extends considerably farther to the south than was known. Another strike on a new property was made last week by the McCormack Bros., Lawrence O'Connor and Henry Moore, known as the Sudbury quartette, who have been following up a small vein on Giroux lake. The vein was found to widen considerably, becoming rich in silver and cobalt. A large nugget of native silver was also found. Mat Murphy, well known in Montreal sporting circles, has sold the south half of Devil's Rock, a point on the shore of Lake Temiskaming a few miles east of Cobalt town, to a Montreal syndicate for about $60,000. It has two eight-inch calcite veins assaying high in silver, with cobalt. Shipments of ore have fallen off of late, as several of the producing mines are storing their output until the Hamilton smelter is in operation.

Much activity prevails in the Boston Creek copper district, some 60 miles to the north of Cobalt, which is overrun by prospectors. The Herron Bros. of New Liskeard, who have taken up 80 acres, have a good vein, and outcrop samples give high assays. Capt. Dan Mosher, a noted prospector of Rainy River, has started on an expedition to Hudson bay in the interest of eastern capitalists. Geo. R. Mickle, lecturer in the Toronto School of Practical Science, has been appointed Provincial Inspector of mining claims under the new mining act. He has his work cut out for him, as a considerable number of the claims under which large areas in the Cobalt camp are held, are of a very dubious character.

The Canadian Department of the Interior is following up the experiments recently made in the smelting of iron ore by the electric process, by ordering an examination as to the extent and value of the iron ore deposits. This step has been undertaken on the recommendation of Dr. Eugene Haanel, Superintendent of Mines. Ever since the successful result of the smelting tests there have been numerous applications from all parts for information as to the iron-ore beds and the possibilities of their development for electric-smelting purposes. Three parties will be put in the field this season to conduct the investigation. One will work in Western Ontario and will be in charge of Mr. Shele; Quebec Province and Eastern Ontario are assigned to Fritz Cickel, while Prof. Woodman will conduct the investigations in Nova Scotia. Magnetic surveys will be made and samples secured for analysis. In addition, the examination will include the water-powers in the neighborhood of the deposits.

MINING SUMMARY

ALASKA.

A rich strike has been made on Holyoke creek, on the tundra just north of Nome within a stone's throw of the Portland bench. The mine is owned by Denhart, Bard and Nixon, two of whom, it is claimed, took out $37,000 in one day. When bedrock was struck, one portion of it was found covered nearly an inch thick with gold. All told, the winter clean-up on the Denhart, Bard, and Nixon claims totals a million dollars. The report of the strike has caused great excitement in the Seward peninsula. It is claimed the new Holyoke creek strike is richer than the Portland bench, and that the tundra around Nome will receive a great share of attention during the coming summer.——C. G. Hubbard of Seattle, and one of the owners of large copper properties in Copper River country, states that the Guggenheims have been trying to purchase their property, but all offers have been refused and it will be operated as an independent property. The thing that will make the Copper River district a big copper-producing region, he says, is the advent of a railroad.

ARIZONA.

COCHISE COUNTY.

A short distance south of Paradise the Oklahoma claim is being opened by S. Gallen and P. B. Warnekros of Tombstone. A tunnel is being driven on a contact of limestone and diorite. Soon after the tunnel was started, copper sulphide appeared and still continues. This vein is 18 in. wide. On one side of it is a soft formation, containing iron and possibly gold. In the soft ground there is also copper. Some of the richest sulphide runs 40% copper, though most of the ore is of a lower grade. Other work on this group includes a tunnel 50 ft., a shaft 15 ft. and several open-cuts. Near the tunnel, there is a spring, the water of which is so impregnated with copper that it leaves a copper stain on the rocks over which it runs.

At the Douglas smelter, of the Calumet & Arizona, the management has under consideration the installation of new reverberatory furnaces, and plans are being prepared for their installation. These will be the first of their type to be used at the Calumet & Arizona. The silica quarries have closed, this flux being replaced by the silicious ore from Globe. For some time the Copper Queen Co. has been experimenting with a view to arriving at a practicable method of recovering the copper which has heretofore been carried away in solution in the waste water from the mines. A small experimental plant was put in, and the results proving satisfactory, the company is now erecting a large plant having approximately 50 times the capacity of the one in use heretofore. The system consists of a series of vats in which are deposited old scrap iron. The waste water is turned into these vats, the copper being precipitated by the iron. The new plant will treat the water from the Holbrook and Czar shafts. After leaving the vats, which are near the Czar shaft, the water will be conducted by flume to a tank constructed by the city, and will afterward be used for sprinkling the streets of Bisbee and Naco road.

YAVAPAI COUNTY.

The Congress management has run a 1,000-ft. drift connecting shafts No. 4 and 5 at a depth of 1,000 ft., in which they have developed strong shoots of sulphide ore in new territory.

It is reported that a discovery of lead-silver ore has been made by Teller W. Daly, of Wenden. The ore runs 58 to 60% lead, 700 oz. silver, and $37 gold per ton. The veins occur at contact of a diorite dike and limestone. The discovery was made near Wenden.——J. E. Kelly, of Thumb Butte district, west of Prescott, is said to have netted $102 per ton on a shipment of ore from his properties in that district, sent to the Humboldt smelter.——Litigation in connection with the affairs of the Crown King Mines Co. of New York, at Crown King, has been settled, and operations at the mines are to be resumed upon a larger scale. New York capitalists have agreed to buy out the faction which has heretofore prevented the company from carrying out all its plans, and sufficient money has been put up to liquidate outstanding claims. The company recently installed a concentrating plant of large capacity to treat the 60,000 tons of tailing which have accumulated. The electro-magnetic separators have been rearranged and now give satisfaction. Work on the mine will be centered on the working tunnel to cross-cut many of the veins at depth.

CALIFORNIA.

AMADOR COUNTY.

The Wildman mill has been started up and rock of good grade is being crushed. A large orebody has been partly developed on the 1,400 level, south, in addition to ore opened in other parts of the mine.

The Gold Top gravel mine at Pine Grove, commonly known as the Wheeler claim, is idle owing to the shutting off of the water supply.——Under the management of Mr. Farwell, the Jose Gulch mine is being put in condition for work. A number of men are cleaning the old Horn ditch, which will take a couple of weeks more to finish. The mill is also being put in shape. C. A. Rice of Mokelumne Hill will have charge of the mill.

BUTTE COUNTY.

Recent heavy rains in the pocket mining district of this county have sluiced out coarse gold in a number of places, and pocket hunters have been more than usually fortunate in consequence, particularly near Rackerby, on the line between Butte and Yuba counties. Quartz mining is also active around Rackerby. A fine vein is being developed on the Rogers ranch, half a mile west of the postoffice.

COLUSA COUNTY.

The Quarrymen's union at Sites went out on strike on June 1. The men are employed by the McGilvray Stone Co. and the Colusa Stone Co. About 35 men are out and the quarries are shut down. The difficulty is over the number of working hours per day, and the wage scale.

EL DORADO COUNTY.

Grading has begun for a 10-stamp mill on the Vivian mine near Greenwood. It is reported that work will soon be resumed in the shaft in the Hidden Treasure.—— Chlorination works are being erected on the Standard Unit mine in Coloma canyon below Greenwood, to treat auriferous sulphide.—— Drifting and cross-cutting is about to begin on the Rosencranz mine, where they are down 520 ft.——The Union mine, four miles south of Diamond Springs, is running with 30 men, and 20 stamps have been dropping at this mine during the past month. D. Humbert is now managing owner.—— Hugh McDougal and N. Behrns have given up their lease of the Bacchi-Collins mine near the Esperanza. John Breen and L. Beck have taken their place and are unwatering the shaft preparatory to doing development work.—— Silas Granger and S. Gray, while sinking on an ore-shoot on the Davidson place near Shingle Springs last week, took out a $3,000 pocket. Eleven pounds of ore, almost entirely gold, were taken out the first day, and $780 worth was found the next day, with more in sight.

Thirty men—splitters, trimmers and blockmakers—are out on strike at the Eureka slate-quarry near Placerville. Some time ago they demanded a raise from $3 to $3.50 per day, and a compromise of $3.25 was offered by the management. This was declined and the men quit work on Thursday of last week, and are still out.

SANTA BARBARA COUNTY.

The discovery of lithographic stone of good quality is reported in Loma Blanca district, 25 miles northeast of Santa Barbara. The company organized to exploit this find owns 800 acres of patented land.

SAN BERNARDINO COUNTY.

The engine and pump to be used in testing placer grounds of the Klinefelter wash, 25 miles northwest of Needles, are being installed.——On the property of the Siam Mining Co., situated near Siam siding, a water station on the Santa Fe railway 65 miles west of Needles, work is being prosecuted day and night. A shaft has been sunk, and two levels run, consisting of 600 ft. of drifts and cross-cuts. Recent development has disclosed free-milling quartz in the upper level running $100 per ton gold, while in the lower level copper ore assaying $90 to $100 gold, with 20% copper has been cut. P. H. McDermott is superintendent.

George Wilson, assistant manager of the Quartette properties at Searchlight, Nevada, has taken under bond a group of copper claims near Cima, in this county. In the district in which the copper claims are situated the principal operating concern is the Standard Mining Co., which is a steady shipper of gold, silver and copper ore. There is a large percentage of iron in the ore, for which the smelters pay a premium. A. B. Hall is foreman of the new mines. Three shafts will be sunk and hoists installed. The property is near the Salt Lake railroad, just south of Nipton.

SISKIYOU COUNTY.

The board of directors of the Siskiyou County Agricultural Society, at a meeting last week, bonded the race-track grounds at Yreka, to John O. Harrison for $7,000, of which $500 was paid, the remainder being payable in two equal payments, in one and two years. There are about 100 acres in this tract. It adjoins the Blue Gravel mine, and it is believed the ancient river channel from which the gold is obtained extends west under the race-tracks. As it is 110 ft. to bedrock, prospecting will be expensive.

A discovery has been made in the lower Salmon River district by Roy Wilson. The vein is from 30 to 60 ft. in width and can be traced two miles. A number of claims have been staked by Wilson, Murray, McLain, McKinzie and others, who have organized a company to develop the property. It is situated in a rough district of the Salmon, and they are now cutting trails and developing the new find. A number of samples taken from the vein where the ore crops out, show gold and copper. Parties from Eureka have bonded two of the claims and have started work. In the same neighborhood the Bennett brothers and others have located claims on Nordheim creek, upon a continuation of the same vein.

Judge Beard has rendered a decision in the Lanky Bob mining suit in favor of G. V. Gray, defendant, vs. C. A. Mitchell and G. G. Skillen, plaintiffs. The Lanky Bob mine is situated in Liberty mining district, in this county. G. G. Skillen was owner of the mine, and bonded the property to C. A. Mitchell for $10,000, of which $5,000 was to be paid in 90 days from date of agreement. Before the expiration of the bond, Skillen sold the mine to G. V. Gray for $12,000, a payment of $6,000 being made in cash. Then Mitchell commenced suit for possession of the mine, but as he had paid no money to bind the bargain, the case was decided in favor of G. V. Gray, who has taken possession of the mine. It is reported that Mitchell will appeal the case.

The Dannenbrink Bros.' quartz mine, on Knownothing creek, head waters of Salmon river, near the Trinity border, has been yielding handsomely of late. It has a quartz-mill and other modern improvements. Work is progressing at the Carlock & Morrison mine in Quartz valley.—— A number of quartz claims have been located in Sec. 30, T 47, R 4 W, where good copper prospects have been found. This is a new district on Klamath river in the Bogus district, where no mining has been done heretofore.—— A rich strike is reported in the Dismal Swamp mine, owned by Jeter & Frakes. The ore assays $70 to $215 per ton and is two feet wide. W. A. Hutton and Albert Spaulding have discovered a ledge in the Elliott Creek district which assays $130 per ton. This find is a new one. The rock in which the ore occurs is black quartzite which crops from 100 to 200 ft. in width. It is situated six miles from Joe Bar on Dutch creek.—— Nathan Durkee, superintendent of the Shaft Rock mine, near Yreka, intends to buy a 20-stamp mill and other machinery for that mine. The wagon road from Gottville to the mine, four miles up Empire creek, is completed, with the exception of two bridges across the creek, and they are in process of construction. Workmen are driving a tunnel on a level with the creek-bed, where the ledge is 12 ft. wide on the surface and carries $12 per ton.

SHASTA COUNTY.

The Bullychoop Mining Co. has appointed Sidney Smith general manager and H. C. Anchor superintendent of the Bullychoop mines.

TUOLUMNE COUNTY.

At the Soulsby mine the Bagdad-Chase Co. are still sinking the Pennsylvania shaft, where the 600 ft. station is about to be cut. At the Davidson shaft of this mine, the company is still unwatering the workings. The water has been lowered 175 ft. The head-frame and hoist are completed and everything is working smoothly.

COLORADO.

BOULDER COUNTY.

(Special Correspondence).—The Isabell Mining Co., operating on Caribou hill adjoining the old Caribou mine, has a shaft down 200 ft. with drifts both east and west. They recently encountered a body of ore assaying $200 per ton. In the east drift they expect to tap the Jay vein, which shows good ore in the upper workings, samples running from $300 to $600 per ton silver. J. R. Elgan, of Denver, is manager.

Caribou, June 1.

CLEAR CREEK COUNTY.

Four teams are hauling ore from the Stevens mill at Silver Plume and two cars of iron concentrate and 40 tons of lead have been shipped. The road from Graymont to the mine is in bad condition, but is improving, as the snow is going off. A large number of men are employed. Development is being carried on, including sinking the shaft on a good vein of ore.——B. J. O'Connell made a shipment of 11 tons of lead and 35 tons of zinc concentrate as the result of a run in the Mendota mill on ore from his leases on the Frostburg vein. Machine-drills are now used.——A large force is putting in the foundation for the lower terminal, and digging holes for the towers of the aerial tramway that is being erected for the Colorado Mines & Aerial Tramway Co. to carry passengers to the top of Leavenworth mountain, and it is expected to have it in operation in about a month.——A good vein of ore is showing in the shaft of the Smuggler, which is being sunk by the Main Gulch Co. There is about a foot of lead-zinc material and a smaller amount of high-grade ore.——The Terrible mill

is running steadily and the working force is being increased. Several machine-drills have been put to work in the mine in order to keep the mill supplied.

LAKE COUNTY.

The mines of Leadville are paying $400,000 per month, in wages, with an open shop. The last fight made by organized labor ended so disastrously for the union, that it resulted in a chance for any good man to get work. A man must present himself to the Mine Managers' Association, prove he is a capable miner, and get a card, when he becomes eligible for work; he cannot get work without this card.

OURAY COUNTY.

There is said to be in Ouray district a scarcity of single and double-hand hammersmen, a class of miners that has gradually been growing less in the San Juan country since the introduction of machine-drills. Machine men and helpers now receive $4 and $4.50 per eight-hour shift. Single and double-hand hammersmen, however, cannot be entirely dispensed with, and the latter class of laborer is now in demand in the district. ——A telegram has been received at Ouray ordering the resumption of work in the Treasury Tunnel Mines Co. adit, at Red Mountain. The order also includes the extension of the drifts at the 300-ft. level in the raise on the Handicap vein, where ten feet of ore has been cut. The mill will resume in August, giving work to 35 men. The Treasury's main working tunnel is in 5,530 ft. and is to be driven an additional 5,000 ft. when it will have intersected the Corn Cob, Vagabond, Schemer, Tomboy, Argentine, Cimarron, and Columbia veins. The Tomboy vein will be cut 1,030 ft. below the bottom of the deepest shaft, which is down 600 ft. The strike of high-grade ore at the Mineral Farm, near Ouray, has been the incentive for renewed activity among the mines and prospects of the lime belt adjoining Ouray. Among those to resume work is the Merchant's Mining Co. on the group to the north of the Mineral Farm, where considerable development has been done in recent years. Some ore is being extracted in driving along the contact, but work is hindered on account of water.

SUMMIT COUNTY.

The $90,000 dredge of the Reliance Gold Dredging Co. opened the placer season in this county three weeks ago, and is running day and night on good gravel.

TELLER COUNTY.

The Doctor-Jack Pot shipped 15 cars in May. Smith & Altman, who have about one-half the Jack Pot property under lease, shipped the most of the ore which came from three shafts, the Jack Pot, Elizabeth Cooper and Davenport. Smith & Altman have the south one-half of the Jack Pot claim and all of the Cooper. Altman alone is now getting good ore from the Chief claim. There are 27 sets of lessees now operating on the Doctor-Jack Pot property, and nearly all are in ore. The Gregory lease, which in 1905 produced $300,000 for Lew Hayden, the lessee, expires in August, when it will be worked by the company.

The strike of a body of two-ounce ore is reported on the 400-ft. level of the Mary Ann claim adjoining the Jo Dandy on Raven hill. This claim had not been operated for several years until recently, when it was leased to an outfit which did considerable development work with the result that ore was soon encountered.

IDAHO.

CUSTER COUNTY.

A gold quartz strike is reported from the Daisy mine of the Sunbeam Co., near Challis. C. E. Cable is general manager. They worked on low-grade stuff last season—$2 to $5—while exploring for better ore. During the past winter a cross-cut was started in the porphyry and a vein that did not show on the surface was cut. It is three to six feet wide and rich in gold. A raise has been put up 60 ft. and drifts run on the vein at the tunnel level. The ore assays from $50 to $100 per ton, and some of it will be sacked. A run was made, as a test, and $8,000 taken out of medium-grade ore. The mill is to be repaired and put in operation as soon as some needed machinery arrives. This mine is on the north side of what is known as Bismarck mountain, and is separated from Estes mountain by Jordan creek, and five miles from Custer and directly on the wagon road to Loon creek.

SHOSHONE COUNTY.

Stanly A. Easton, manager of the Bunker Hill & Sullivan Co., states that the savings of the company by its experimental tailing plant, recently installed, are of sufficient magnitude to justify the company in putting in a large plant with which to re-work its entire dump, which contains 1,000,000 tons of tailing from the concentrator—the accumulation of nearly 20 years. The tailing assays from $2.50 to $4.50 per ton silver and lead, most of which can be saved by the process with which the company has been experimenting since early last spring.

MICHIGAN.

HOUGHTON COUNTY.

The Allouez and Centennial mines both made good records during May, showing an increase over the output of former months. The Allouez during May yielded 514,630 lb. copper and the Centennial 310,000 lb. Allouez during the month made no advance in its No. 2 main shaft on account of the volume of water there. The shaft is 80 ft. deep, and it is thought that a few feet additional will reach solid rock. Drain shafts close by have encountered the rock at about the same depth as that now attained in the No. 2 main shaft.

Mining in the Tamarack will be resumed in a few days in the three shifts which were closed on account of the fire. The conflagration which started in No. 2 shaft more than five months ago, has been extinguished. It is expected that work will be resumed in No. 5 shaft first, as that is a downcast shaft, and there is less danger from gas in its workings. Men went underground in No. 5 shaft this week and found little gas. There is a scarcity of experienced miners in the Lake Superior copper district, owing to the great activity at all the mines. Many of the men who worked at the Tamarack have obtained work elsewhere. The prosperity caused by the present price of the metal is evidenced on every hand. The construction of the Keweenaw Central railway requires a large force, and the paving of the streets, laying of cement sidewalks, and exceptionally large amount of building work under way in various towns, gives employment to several thousand men. The Calumet & Hecla Mining Co., which recently obtained control of the Nonesuch mine in the Porcupine Mountain copper range in Ontonagon county, will begin extensive diamond-drill explorations on the property. An excellent copper showing has been made on the Keweenaw Copper Co.'s property, in Keweenaw county, in the last few days. One of the old shafts at the Medora mine was unwatered and cleaned out, and in the bottom good ore was found. This shaft was sunk to a depth of 50 ft. probably 40 years ago, in what is known as the Medora amygdaloid bed. The identity of this bed, however, is uncertain.

MARQUETTE COUNTY.

Orders have been placed for the necessary timbers and machinery for the mill to be erected by the Ishpeming Gold Mines Co. at the Michigan gold mine, northwest of Ishpeming. Work on the foundation for the plant will start in a few days. The structure will be erected near the main shaft, with which it will be connected by tramway. The plant will have a capacity of 10 tons daily, crushing through an 80 screen. After leaving the plates the tailing will pass through a process for the recovery of other mineral, finally going to a tube mill, where the quartz will be ground into silica powder of 250 mesh. The silica powder it is said will sell for $18 per ton. Mining operations may not start until the mill is completed, as there is ore enough on the surface to supply the mill for six months. The mine is equipped with hoisting and other machinery.

MONTANA.

SILVER BOW COUNTY.

It cost the North Butte Co., of Butte, 4.38c. per lb to produce its copper in April. By August, when the new hoist is working, the company will be hoisting 1,500 tons of eight per cent ore daily.

NEVADA.

CHURCHILL COUNTY.

Among the prominent mines in Fairview district are the Nevada Hills, Wingfield group, Boulder group, Ida M. group, Harnan group, and Lena, each of which has several veins. The Nevada Hills has the best showing at present. The ores are chlorides and sulphides, silver predominating. One shipment has been made from the Nevada Hills and another shipment is sacked and ready. The mineral zone covers an area five miles square, every inch of which is located. About 100 men are working in and about the mines. There are many idle men in camp, and it is not advisable for miners and laboring men to go to Fairview for some time, in search of work. Supplies are hard to get, the growth of the camp exceeding hauling facilities, but fairly good board can be had for $10 per week. Water costs from $2.50 to $3 per barrel; wood, $20 per cord. Miners' wages are $4.50 and $5 per day. A strike has been made on the Wingfield, and another in a cross-cut on the Harnan. Numerous other reported strikes have in almost every instance been verified.

ESMERALDA COUNTY.

Good strikes are reported from near Alkali Springs, seventeen miles northwest of Goldfield. For two days last week the stream of gold seekers poured from Goldfield into the new district. The ore taken out resembles that of Tonopah. The samples brought from this district assayed $77. Picked samples went $5,000. The district is eight miles long by three miles wide. It is five miles from the railroad, with wood and water near.

LINCOLN COUNTY

(Special Correspondence).—An innovation in mining company organization will be introduced into Searchlight district, by a new company organizing under the title of the Searchlight Consolidated Mines, Ltd., with a capitalization of 5,000,000 shares, par value $1, of which 4,000,000 shares have been placed in the treasury. The company has acquired 20 claims in the northern end of the district, and is preparing for extensive development. Two gasoline hoists 25 and 10 h.p., respectively, will be installed. Ogilby Woods is superintendent, and will have charge of the company's entire holdings.——According to a statement of Mr. Hurt, the Golconda Mines Co. is about to begin operations on their property which joins the Gold Dike on the north and east.——The officials of the Cyrus Noble Mining Co. of Redlands, Cal., have paid a visit to Searchlight, the company's main office, to look after their interests, both in this district and in El Dorado canyon. As a result of their visit the Gold Dike Co., controlled by them, will start in with renewed energy.

Summit Springs and Sunrise, the districts east of town, are unusually active, and reports from Summit Springs are to the effect that ore running from $10 to $75 is being blocked out on the main property of this section. Numerous groups are being incorporated and put in condition for development. At Sunrise several groups have been sold to Minnesota and Pittsburg capitalists, and the first rush to this district four months ago when hundreds of claims were staked, is resulting in development, which in nearly every instance, is meeting with better results than was anticipated. Should this excellent showing continue with depth Searchlight will expand into a larger and more prosperous district. A large number of freight teams, loaded with supplies, are passing through Searchlight en route to El Dorado canyon and Nob Hill, and by the time the railroad is completed into Searchlight the El Dorado and Nob Hill district will have enough ore of a shipping grade blocked out to supply the new railroad with a large amount of return freight, as all shipping ore will be held until the completion of the railroad.

Searchlight, May 29.

NYE COUNTY.

Miners' wages in Bullfrog district are stated to be for eight-hour shift, as follows: Foreman, $8, shift boss $6.50, sinking $5, surface work $4.50, drifting $4.50. Underground work in Butte $3.50; Tonopah and Goldfield $4.

OREGON.

BAKER COUNTY.

(Special Correspondence).—All the mining camps surrounding Baker City are active, but the greatest interest is in the development of the copper belt to the northeast. The orebodies suffer nothing in comparison with other copper sections of the country. At the Indiana mine, near Medical Springs, which is in charge of J. W. Messner, the average is eight per cent copper, and from $5 to $8 per ton gold and silver. Most of the available ground, between the Indiana mine and the North American property, at Burkemont, has been staked, and many new prospects will be opened along this belt during the present year. At Burkemont, which is near the geographical center of the copper range, D. W. C. Nelson, manager, is down 300 ft. with a double-compartment shaft, on the North American, and has passed through 85 ft. of native copper ore. For souvenirs of this period in the history of the copper development of this region he is having struck from the first copper produced, medallions, about the size of a silver dollar, with an engraving on one side of the North American shaft-house, and on the other, an inscription with date of issue. On Goose creek, in the property of C. C. Cox, the discovery of bornite is announced. The development of this property has just commenced.

Above the copper belt and higher on the range, near the foot of the Eagle mountains, is the Cornucopia camp, in which a number of mines are located around an old gold producer, heretofore owned by John E. Searles of New York. This is the Union-Companion, which is reported to have recently passed under the control of the Guggenheims. The force has been increased to 100 men, and the property is outputting about $50,000 per month. Adjoining the Cornucopia, the Mayflower, G. W. Boggs, manager, is completing a cyanide plant, and the reduction of ore from this property will begin early in June. The ore-bins are full, and large reserves are being blocked out in the mine. Not far from the Mayflower, the Queen of the West Co. is preparing ground for the erection of a 10-stamp mill, and this property is

expected within a short time to join the list of producers in Cornucopia camp.

To the west of Baker City, and lying above Powder River valley, at the base of the Blue Mountain range, Edward I. Field, of the United Elkhorn mines, is shipping concentrate steadily from the Baisley-Elkhorn. Since this property passed into the hands of F. M. Hayes of Philadelphia two years ago, development has been proceeding, both underground and on the surface. An electric power-plant was first installed near the foot of the mountain on which this mine is situated, and a heavy expense was eliminated thereby, in transporting fuel up to the workings, which are 3,000 ft. above the valley. Other features were introduced, involving a large initial outlay, and an adit is now being driven to cut the orebodies in this property at a depth of 2,000 ft. One hundred men are employed at this mine, and it is reported that the Salt Lake smelter has contracted for the entire output of ore from the United Elkhorn, and that the concentrate is now being shipped there. Over the summit from the Elkhorn, the Highland property, which recently emerged from a siege of litigation, has resumed operations on a large lode. The new concentrating plant on this property has a capacity of 50 tons daily.

At Timber Canyon, Frank J. Davey, manager, is running ore out of a new tunnel on the property of the Timber Canyon Mines Co., and preparation is making for the erection of a mill at this mine about the middle of July. In the Quartzburg district, the Standard mine is steadily producing, as is also the Equity Mining Co., together with the Copperopolis. Aside from these, a number of promising prospects are being opened.

There is hardly a stream or dry gulch in Baker county that has not yielded, or would yield, placer gold, if water were available. The deep snows of the past winter have been advantageous to alluvial mining, and many new diggings have been opened. Several companies are operating at Stice's gulch, and its tributaries, and all are getting good returns. Fred Eppinger, manager of a local organization known as the Merchant's Co., has just come in from Cow creek with a fruit-jar full of gold estimated at $4,000, the result of a short run through the sluice boxes on the property of his company. Several of the nuggets will weigh 5 oz., and many of them will run from $5 to $20. All the gold is coarse and easy to save. In ordinary years this property yields about $20,000, but the increased supply of water this season will enable the owners to make a longer run, with the expectation of doubling that amount. In the old Sparta camp, that has produced millions in placer gold, W. F. Talmage is at the head of a company which has a ditch from the Eagle river that will afford a constant water supply in the development of new placer ground. He has completed a bed-rock flume and will work a large force during the present summer, in Saw Mill gulch.

Baker City, June 5.

SOUTH DAKOTA.

LAWRENCE COUNTY.

From the 165-ft. level of the Homestake South Extension driving east and west is continued with day and night shifts. This level is to be explored before going deeper. This company is operating 2,000 ft. southeast of the Ellison hoist of the Homestake on a system of mineralized veins.—— On the Mark Hanna group, at the head of Two Bit gulch, four miles southeast of Deadwood, free gold ore has been found 400 ft. below the surface in a vertical vein. The ground is owned by Nick Treweek, State Mine Inspector, Mrs. Joseph Treweek, of Lead, and Thos. Thomas, of Two Bit.

The Kildonan mill, at Pluma, situated about midway between Deadwood and Lead, is being put in shape for resumption of treatment of Horseshoe ore. The changes contemplated are so numerous that the mill will practically be rebuilt. Arrangements will be made to treat a large volume of slime. Electric power will be utilized.——Rolls to crush dry are being put in by the Gilt Edge-Maid Co., replacing Chilean mills.—— The miners of Bald Mountain district, aided by merchants of Deadwood, are considering the installation of an aerial tramway to connect the mines of the Bald Mountain district with the reduction works at Deadwood. The mine-owners and ore-shippers claim the railroad charges are too high, and that the proposed tramway will prove a good investment.

PENNINGTON COUNTY.

At the Mariposa mine near Mystic, development is being pushed. Compressor and machine-drills were recently installed. The company is driving a tunnel to develop the veins at 400 ft. depth. There is a good surface showing on the top of the hill.—— Rich ore was found last week at the Sullivan mine, five miles southwest of Rochford on Castle creek. The ore is white quartz, rich in gold. The Sullivan mine has frequently produced similar ore in the past. Owners of the neighboring property are bestirring themselves to locate the extension of the vein.

TEXAS.

BREWSTER COUNTY.

Two new quicksilver finds in Brewster county have caused an impetus to the mining industry there. One of these veins is several miles east of the Lindsey & Dallas property and is now being worked, investigations with diamond drills having discovered a large body of ore. The other field is a few miles northeast of the Cigar Springs mountain. The two new fields are a hundred miles apart and are taken as indicative of the wide scope of country available for development of quicksilver. The opening of the coalfields in the Big Bend of the Rio Grande, contiguous to the quicksilver mines, solves the fuel problem in the district, and development is making rapid progress.

UTAH.

SAN JUAN COUNTY.

Heretofore the mines in La Sal district have been too far from railroads, and separated from them by such poor roads that the owners of property have done little development. Within the present year there has been a movement in several localities to better the roads to shipping points, and within the next few weeks there will be better roads leading from the various points of the range. There is an influx of miners and investors into several regions along these mountains, and property owners are developing their claims. The chief interest has attached to the Beaver Basin district. Opposite the Beaver Basin, on the other side of the range, is Miners' Basin, in which a large property was recently sold. The new company is building a wagon road from Castleton to the head of Castle creek. At Gold Basin, at the southern end of the range, the Intermountain Co. expect to have their mill ready for operation by June 1. Up to the present they have been handicapped by snow. The Salt Valley copper properties, 15 miles from Thompson springs, are giving good results. The properties in Sinbad valley on the east slope of the La Sals, are getting busy. One company of Colorado capitalists intends to develop its properties, is building a mill and has secured many claims near the original group. They also are building a wagon road to Grand Junction.

SUMMIT COUNTY.

At the Daly-West mine, Park City, as a result of a refusal on the part of the miners to take oil-lamps into the mine, for the purpose of comparing their use with that of candles, all the men, with the exception of a few timbermen, are out, and insist that they will not return to work under present circumstances. The first trouble came a few days ago when the men who were about to go on shift refused to take lamps with them. Other shifts refused in the same manner, so there is practically no work being done in the mine, and as a result the mill force will have to be laid off, unless the trouble is settled. About 200 men are out. The miners claim that the lamps are unhealthful, dirty and inconvenient, and believe they are being imposed upon when asked to use them. They claim that they have given the lamps a fair trial and have found them unsatisfactory. Ernest Bamberger, manager, says that all he has asked from the men was a fair trial of the lamps, and this they had refused. For two or three shifts, a few of the miners had tried the lamps, and the shift-bosses gave favorable reports on their use during this time. Thursday evening, without giving any notice whatever, the men refused to go into the mine.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Pearl Consolidated Mining Co. shipped 17 carloads of ore up to May 22, being more than all that was shipped during April, and there were three additional cars ready. All of it came from the Lone Pine lower level and was sent to the B. C. Copper Co. at Greenwood, B. C. On account of changes being made at that company's smelter, no more ore will be shipped there until the alterations are finished. Carload samples are to be sent to Denver and other points to be tested for milling processes. There is a large quantity of low-grade ore in the Lone Pine, Pearl and Surprise claims, owned by the Pearl Co. The nearest approach to successful mill treatment of the ore of Republic camp was a modification of the cyanide process made in the Republic mill, which has been dismantled within the past 18 months. It was built at a cost of $350,000, but was not supported by the mine owners of the camp, and shut down when the orebody in the Republic mine pinched, after which only a little exploratory work was done below the mill-tunnel level. In the Lone Pine workings the cross-cut from the South drift is complete and the drift driven ahead, and there is now good ore in the face.

Republic, May 31.

(Special Correspondence).—During the week the Pearl Consolidated Mining Co. shipped ten carloads of ore from the Lone Pine workings.—From the Ben Hur mine shipments were about the same as for the previous week.—Ingham and Witcher, who for the past six months believed they had found a deposit of molybdenite on their ranch, on Cayuse mountain, Okanogan county, now realize that the mineral is stibnite. Samples run from 70.1 to 43.3% antimony. Eastern ore buyers have offered $2 per unit for the ore, and the railway offered transportation for $23 per ton.—The Q. S. Gold Mining and Smelting Co. continue to find ore of shipping grade in their tunnel and is figuring on driving another tunnel at the base of the mountain to cut the vein at a depth of 3,000 ft. A gravity tramway is to be constructed and a sawmill will be installed for cutting timbers for the mine and camp buildings. In case the lower tunnel should be driven a large compressor will be put in.—The Golden Chariot mine, situated five miles northwest of Oroville, an old camp on the Vancouver, Victoria & Eastern Railway, now under construction, was purchased two years ago by a syndicate of Spokane, Wash., Minnesota and Dakota people, and the Golden Chariot Mining and Smelting Co. incorporated. Last fall a vertical shaft was started and sunk 100 ft. At 30 ft. a pay shoot was cut, and drifts were driven north and south on the vein. Recently in the south drift a winze was sunk 25 ft. on ore that assays $25 to $40 per ton.—The Elone Mining Co. is operating three claims in the Methow Valley district, near Twisp, developing a 30-ft. vein. The ore assays $5 to $30 per ton, mostly gold.

Republic, May 22.

FREMONT COUNTY.

J. H. Lobell, head of the Belgo-American Drilling Co., owning extensive oil fields in Wyoming, has filed on 2,460 acres of placer land in the Oregon Butte country near Lander, and it is reported that gold has been discovered. A pumping system is to be installed to develop the placer fields.

OKANOGAN COUNTY.

(Special Correspondence).—In Myers Creek district the Mad River Mining Co. has developed an orebody assaying $40 to $65 gold and silver, with considerable zinc-blende. The main shaft is down 400 ft. and the company has a large quantity of ore ready to ship when the Vancouver, Victoria & Eastern Railway can transport it to the smelters.—The Sarauas adjoins the Mad River property and is preparing to increase the present force. A saw mill of 5,000 ft. daily capacity, and mining machinery, are to be installed.—The Wyandotte Mining Co. has struck galena, carrying silver.—The Bimetallic Co. expects to spend $10,000 this year on buildings, a new shaft, and development work.—The Olentangy Co. will install machinery at its shaft, which is now down 85 ft. A tunnel has been driven 50 ft. and ore has been developed in both which runs from $25 to $60 per ton gold and silver.—The Medallion Co. has a shaft down 100 ft. and is driving on gold and copper ore which runs $16 per ton.—The Ben Harrison Co. reports that it has ore enough on the dumps for a three years' run and will start up its mill June 15. This company is driving a 500-ft. tunnel.—About $100,000 has been spent on the Crystal Butte mine in tunnel and shaft work, and operations will be resumed as soon as transportation for the ore is available.—It is reported that the B. C. Copper Co., of Greenwood, B. C., will take up an $80,000 bond on the Grant mine and commence development. There are eleven claims in the group. The main workings show a body of ore 20 ft. wide, which runs $14 per ton. The ore is pyrrhotite, containing copper and gold.—On the Butcher Boy a streak of ore that assays $160 per ton gold has been followed from the surface, where it is five inches wide, to a depth of 80 ft., where it is 20 inches wide. The mine is under bond and the operator, having taken out enough to pay all expenses of the mine for six months past, will take up the bond and ship the ore. The shaft will be sunk to the 100-ft. level, and machinery will be placed on the mine.—John E. Boyd, general manager, and E. W. Beidler, superintendent of the Palmer Mountain Tunnel and Power Co. are in the East. Mr. Boyd went to Denver to purchase electric drills and examine machinery for a 300-ton mill. They will return shortly to the mine and the operations at the tunnel will be resumed. It is now in 4,000 ft. and has crossed 24 veins, the last at a depth of 1,390 ft. One of the veins is 30 ft. wide. Mr. Boyd told the writer that he figured that all the ore in sight will average about $10 per ton.

Chesaw, May 18.

CANADA.

BRITISH COLUMBIA.

Men are at work on the Big Copper mine, in Copper camp, four miles from the Mother Lode mine and eight miles from Greenwood. A deal has been made for the Big Copper, on an option and bond, the property

being taken by Boston capitalists, who have started development. W. T. Smith of Greenwood and J. C Haas of Spokane, took the bond for their principals. The Big Copper is owned by John Moran, S. W. Mc Michael of Toronto, and George B. McAulay estate. In the last few years several attempts have been made to secure the property, but up to this time none of them has been successful. Nearly 600 tons of Big Copper ore were shipped to the British Columbia Copper Co.'s smelter at Greenwood last winter, which returned nearly $14 per ton. As the mine is three miles or more from the Mother Lode spur of the Canadian Pacific railway the ore, up to the present has been hauled on wagons to that point for shipment to the smelter. The ore at the Big Copper is mined by glory-hole method. William Hanna is in charge.—High-grade copper ore has been struck on the Maple Leaf property on Franklin mountain. The orebody has been stripped for 80 ft. and the width is 15 ft. It is reported the samples assayed ran 16% copper. The Maple Leaf is one of a group of five claims owned by W. H. Young of Vancouver and the Fee Bros. of Grand Forks.—The total output of the Boundary mines and treatment at district smelters exceeds 500,000 tons for this year. The following figures are for the week ending May 26: To Granby smelter, Granby mines, 16,055 tons; to British Columbia Copper smelter, from Mother Lode, 4,128 tons; from Emma, 260 tons; to Dominion Copper Co.'s smelter, from Brooklyn-Stemwinder, 2,805 tons; from Rawhide, 462 tons; from Sunset, 792 tons; from Mountain Rose, 36 tons; to Nelson smelter, from Emma, 90 tons; total shipments for week, 24,628 tons; total shipments for year to date, 509,539 tons. The three district smelters treated this week: Granby smelter, 16,712 tons; British Columbia Copper smelter, 4,205 tons; Dominion Copper company smelter, 4,095 tons; total treatment for the week, 25,012 tons; total treatment for the year, 521,626 tons.

Following is the tonnage of ore shipped from and crushed at the Rossland mines for the week ending May 26: Centre Star, 2,880; Le Roi, 2,490; Le Roi No. 2, 450; Jumbo, 130; total, 5,950; total for year, 131,565. At Le Roi No. 2 the concentrator is in steady operation. Early the coming month another shipment of concentrate will be made. The smelter of the Consolidated Mining & Smelting Co. of Canada, Ltd., at Trail, received, besides ore from the Rossland mines, the following quantities: St. Eugene, 496 tons; Silver King, 69 tons; Snowstorm, 68 tons. The total received, 5,972 tons. The erection of the large copper furnace continues, and it should be in condition to be blown in in about a month.

The Glouster group of copper properties in Glouster camp have been bonded to the Dominion Copper Co By the terms of the bond development work will begin now and be kept going until the bond is lifted. Cash payments are to be made at stated intervals during the life of the bonds. The Glouster properties are owned by Thomas Newby, Lee Mercer and Howard Garnett. This group was bonded a few weeks ago by G. A. McLeod, who turned the bond over to the British Columbia Copper Co. and now the Dominion Co. has acquired the entire group. It is reported that the Diamond Hitch property, will be added to the list of working mines. The Diamond Hitch has a large showing of iron ore with copper. On the dump at this claim are several tons of iron ore which were taken from the workings. The Diamond Hitch lies on Pathfinder mountain, and is owned by residents of Grand Forks.

The output of the Boundary mines for the week ending June 2, was as follows: Granby mines, 15,756 tons; B. C. Copper Co. Mother Lode, at Deadwood, 2,201 tons; Dominion Copper Co. at Phoenix, 1,947 tons; Rawhide, at Phoenix, 396 tons; Sunset mine, at Deadwood, 759 tons; Mountain Rose, at Summit, 30 tons; Emma, at Summit, 264 tons; Sally, at West Fork, 25 tons; Butcher Boy, at West Fork, 9 tons; Providence, at Providence, 40 tons; Don Pedro, at Skylark, 20 tons. Total, 21,437 tons. The smelters during the week treated ore as follows: Granby Co., 17,177 tons; B. C. Copper Co., 2,473 tons; Dominion Copper Co., 3,132 tons. Total, 22,782 tons. The week's tonnage from the B. C. Copper Co.'s Mother Lode mine, as well as the amount treated at the smelter, is somewhat smaller than usual, owing to the preparations for blowing out the furnaces to permit extensive enlargements. For the month of May the tonnage of the Granby Consolidated will be smaller than usual, owing to a continuation of changes and improvements. When these are completed the output will be crowding the 80,000 ton mark, making 2,200,000 lb. copper monthly. The report is current that an option has been given on the B. C. mine in Summit camp which is owned by the B. C. Chartered Co. (Ltd). This property in the past has shipped 100,000 tons of copper ore. A spur of the Canadian Pacific railroad runs to the B. C., which has a full equipment of machinery.

Personals.

Walter Douglas is at Santa Barbara.

John B. Farish is in San Francisco.

Forbes Rickard is at Chihuahua, Mexico.

Charles Butters has returned from Chicago.

D. J. Sayer, of Denver, is on a visit to New York.

Edward H. Benjamin is examining mines in Idaho.

F. F. Sharpless is at Kamloops, British Columbia.

R. Gilman Brown has returned from British Columbia.

Carlos Cadmus, of Broad Run, Virginia, is at Havana, Cuba.

J. C. Ralston has an office at 464 Eleventh St., Oakland.

Chas. W. Abbott is at Minas de Alotepeque, Guatemala.

Clarence K. McCormick, of Salt Lake City, is at Paris, France.

Herbert T. Butcher has returned to England from Mexico.

Willard P. Hatch, of Goldfield, Nevada, is visiting at Oakland.

J. Power Hutchins is expected in San Francisco from New York.

Jas. W. Abbott was in Berkeley this week; he is now at Denver.

Lionel Lindsay is visiting the mining camps of Utah and Colorado.

W. R. Feldtman is on his way from London to Western Australia.

Wilbur E. Sanders has returned to Helena, Montana, from British Columbia.

Philip Argall has been elected president of the Colorado Scientific Society.

W. G. Swart, of Denver, visited Berkeley on his way from British Columbia.

David T. Day is at Portland, Oregon, attending to experiments on black sand.

E. W. Sebben has returned to Denver from the examination of mines in Arizona.

G. W. Borrowe is superintendent of the Sons of Gwalia mine, in Western Australia.

Richard B. Stanford is at Woodcliff, New Jersey; he returns shortly to Nicaragua.

J. H. Hartley, lately in the Terlingua quicksilver district, Texas, is now in Berkeley.

E. C. Engelhardt has been appointed superintendent of the Cooke City smelter, Montana.

H. C. Anchor has been appointed superintendent of the Bullychoop mine, in California.

Albert G. Kitchin is on his way from England to examine mines in Western Australia.

Chester Naramore, of the U. S. Geological Survey, has gone to Cripple Creek, from Denver.

A. A. Steel is associate professor of geology and mining in the University of Arkansas.

H. G. Murray is on his way from San Francisco to Japan, where he has an appointment.

C. W. McArthur is erecting the mill for the Gold Prince Co. at Animas Forks, Colorado.

William Magenau has been appointed manager of the National Rubber Company, in Durango, Mexico.

L. B. Davenport, recently superintendent of mines near Nashville, Cal., is now on a visit at Berkeley.

R. H. Goodwin, engineer of the British Guiana Consolidated Gold Mines, Ltd., has arrived in London.

Horace F. Evans has been visiting the Similkameen district and is now near Princeton, British Columbia.

James P. Colp has been appointed manager of the Arden Falls Mining Co. at Monumental Falls, California.

Sidney Smith has succeeded W. R. Beall as general manager of the Bullychoop copper mines in Shasta county, Cal.

A. T. Holman, superintendent of the Golden Cycle mine at Cripple Creek, is taking a vacation on the Atlantic coast.

John O. Harrison, who bought the race-track grounds near Yreka, Cal., for mining, is in charge of prospecting operations there.

F. C. Carstarphen has returned to Denver from Portland, Colo., where he has been the past six weeks for the Portland Cement Company.

Richard C. Shaw sailed from Boston on June 1 for Miramar, Costa Rica, where he will become general manager of the Montezuma mine.

Bert Peterson passed through San Francisco, on his way from New York to Mexico, where he has taken up El Rayo mine, in Chihuahua.

Edwin W. Mills has resigned as assistant superintendent of the Oriental Consolidated Mining Co., Chemulpo, Korea, to become superintendent of the Chiksan mines of Korea, which are being exploited by the Korean Exploration company of Kobe, Japan.

T. H. Oxnam has resigned his position as consulting engineer and general manager of the Palmarejo & Mexican Gold Fields, Ltd.; he is proceeding to England for a few months' rest.

George Hallett, of London, director of the Palmarejo & Mexican Gold Fields, Ltd., in Chihuahua, Mexico, has been spending a week with T. H. Oxnam, at Los Angeles, on his return from the mines in Mexico. He sails for London on June 21.

Obituary.

John B. Francis, who for many years has been superintendent of the Argonaut mine at Jackson, Cal., and identified with other California mines, died last week at Jackson. Mr. Francis was severely injured at the Argonaut mine several years ago in an over-winding accident, from the effects of which he never fully recovered.

Joseph C. Thomas, head mining captain of the Michigan mine, and one of the pioneer miners of the Lake Superior copper district, died at the North Michigan general hospital at Calumet, Mich., a few days ago. Captain Thomas was 66 years old and had been identified with the mining industry all his life.

Dividends.

On June 4 the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 106, of $180,000, making the total paid since January 1, 1906, $1,680,000, and total to date, $6,606,000.

Trade Treatises.

Mine and Quarry, is the title of the newest publication of the Sullivan Machinery Co. of Chicago, Ill. This interesting little magazine is to be issued regularly, its purpose being to give up-to-date information on the subject indicated in the title, and to familiarize its readers with Sullivan machinery. No. 1, Vol. 1, contains the following: Editorial, Rock Excavation on the Panama Canal, Method of Mining at an Illinois mine, Diamond Drilling, Power Extension of the Chicago Drainage Canal, Low Cost of Compressing Air for Drills, Cleaving Granite by Compressed Air, and Suggestions for Operating Rock Drills. The work is nicely illustrated.

Chalmers & Williams of Chicago, 1553 Railway Exchange Building, have issued a handsome catalogue (No. 1 Section F.) of their gold and silver mill machinery, and also concentrating devices. It is well illustrated with line cuts which could be used as working drawings.

The Allis-Chalmers Co. has issued Instruction Book No. 5006, giving full directions for setting up and operating the Gates ball mill which is finding constantly more extended use where fine grinding is necessary.

Rand Air and Gas Compressors are described and illustrated in Catalogue R 37, issued by the Ingersoll-Rand Co. of No. 11 Broadway, N. Y. The book is finely illustrated and contains much information of value to users of compressors.

The Robins Conveying Belt Co., Park Row Building, N. Y., have issued an interesting illustrated booklet, Bulletin No. 15, describing their belt conveyors and automatic-tripping devices for the transportation and distribution o fall kinds of mineral, at greatly reduced expense for handling.

Books Received.

Professional paper No. 49 of the United States Geological Survey treats of the geology and mineral resources of a part of the Cumberland Gap coal field of Kentucky.

Of the **Geologic Atlas** of the United States there have recently been received No. 132, Muscogee, Indian Territory; No. 133, Ebensburg, Penn., and No. 135, Nepesta, Colorado. The price of each of these is 25 cents.

The Geography and Geology of Alaska, is the title of Professional Paper No. 45 of the United States Geological Survey. This publication summarizes the existing knowledge of our most northerly territorial possession. It will be found useful to those interested in Alaska and its resources.

Gold Dredging. Supplement, 1906. By Captain C. C. Longridge, London. The Mining Journal. This is a supplement to the earlier volume, it being the intention to issue annual supplements until the additional material warrants a new edition of the book—which is an excellent plan. Capt. Longridge gives much useful information and despite the widespread character of dredging operations, he manages to keep in touch with them. Five hundred dredges are said to be at work in different parts of the world. To those in charge of them, this book should be of immediate value and also to the large number of people indirectly interested in dredging for gold.

The Directory of Agencies, Mines and Haciendas, of the Republic of Mexico, for 1905-06, has been received. The volume is what it purports to be,—an official directory, which includes the names of manufacturing firms, mining companies, etc., together with their addresses, and usually the names of managers or resident representatives or agents. It will be found indispensable to those having business interests in Mexico. The mining directory is arranged alphabetically by States. The work throughout is in Spanish and English, so that the reader may fully understand, if acquainted with either language. Sent by the Mining and Scientific Press to any address upon receipt of price $5 gold. American Book & Printing Co., 1 A San Francisco, Num. 12, Mexico City.

Commercial Paragraphs.

The Keuffel-Esser Co., of New York, has ordered from the Crocker Wheeler Co., of Ampere, N. J., one of their form L motors of 1 h.p., to drive their blue print machines.

The Penn Hardware Co., of Reading, Pa., are installing a 150-h.p. Koerting gas-engine to be run on producer gas; this engine is supplied by the De La Vergne Machine Co., New York.

The Utah Mining Machinery & Supply Co., J. E. Galigher, manager, of Salt Lake City, reports shipment of Callow traveling belt screens to South Africa, Australia and England; also Callow settling tanks to the Federal Mining Co., Wallace, Idaho, and Ohio Copper Co., Bingham, Utah.

A cyanide gold mill of 500-ton capacity is reported sold by **Fairbanks, Morse & Co.** The entire plant will be operated by Fairbanks-Morse direct-current dynamos and motors, driven by water-power, a 240-ft. head being available. The mill will be near Boulder, Colorado, and will be modern and complete in every way.

The laboratory of the firm of Simonds & King, at 417 Montgomery St., San Francisco, having been destroyed by the fire, in common with all others in the City except the Government laboratories at the Mint and Custom House, they have decided to discontinue the partnership, and will take up separate lines of work. All persons having claims against the firm are requested to send statements of account to 1311 Franklin St., Oakland, and all old customers indebted to the firm will confer a favor by remitting to the same address. Mr. King will continue the former assay and analytical business, including ore testing, etc., and has equipped his laboratory with a complete outfit for assaying, analyses, and ore testing, including laboratory-crushers and grinders run by power, thus insuring rapid and accurate work. His office and laboratory will be at 1311 Franklin St., Oakland. Mr. Simonds will engage in practice as a metallurgical engineer, and will confine his work entirely to ore-treatment, including ore-testing, the devising of methods of treatment and the design and supervision of ore-reduction plants. His office for the present will be at 2842 Hillegas Ave., Berkeley, California.

The Devil's Tower.—Geologists are not agreed upon the origin of the strange-looking mass of igneous rock, called the Devil's Tower, which stands near the north brink of the canyon of the Belle Fourche river, near the South Dakota-Wyoming State line. Its composition is approximately that of typical phonolite, but whether it is a volcanic 'plug' or 'neck' or is merely a residual mass of a once large sheet of lava is a question yet undetermined. The greater number of geologists who have visited the columnar rock-mass believe it to be a plug which was injected into older sedimentary strata which have since been removed by erosion. Others insist that as the columns are practically vertical, it is a remnant of a sheet of igneous rock, all of which has been removed by erosion except this tower-like peak. The theory upon which this is based is that columnar structure in basalt and other volcanic rocks always develops in a direction normal to the flow of lava stream or dike. In streams of molten rock this is true, but the Devil's Tower seems rather to have been a plug than a stream. About forty miles to the southward is a peak known as Inyan-Kara, formed by the intrusion of lava from below, the sediments having been lifted on all sides of the central mass—what is known as a postular uplift. The core, or neck, is columnar, much like the Devil's Tower, the ohief difference being in the almost complete removal by erosion of the sedimentary beds which once surrounded the latter, and the covering of their remnants about the base of the tower by the lava blocks and columns which have fallen from its nearly perpendicular sides. No ore deposits are known to exist in connection with either the Devil's Tower or the Inyan-Kara peak intrusion.

EDITORIAL.

IT IS PROPER to state that the inferior paper used in this issue is due to causes beyond our control. After the earthquake-fire we managed to secure a supply of good paper, pending the arrival of our regular stock. But the best laid plans are disarranged by such conditions as have been faced recently. Our paper has arrived at the railroad terminal but, owing to the congestion of traffic, it cannot be secured. There are 1,400 cars in the Oakland railroad yards which are not identified by reason of the confusion and the extra labor thrown on the officials. The traffic created by the demand for food-stuffs and supplies of every kind has been unprecedented.

TO THOSE WHO take no interest in earthquakes and their geological relations, we apologize; for this issue is rich in matter relating to this subject. But it won't occur again. In our issue of April 28 we gave the impressions and facts available immediately after the disaster of April 18, and now we publish the well-considered views of leading scientific men who have had an opportunity to investigate the facts. After this we expect to drop the subject. To those who, for reasons prompted by science or humanity, are interested in the explanation of the events that led up to the destruction of a great city and permitted of the observation of a rare geological occurrence, the pages that follow will be welcome.

THE RECORD of the Calumet & Hecla Mining Company is calculated to encourage investment in mines. Up to the end of 1905 it has produced 1,811,400,000 pounds, or about 800,000 long tons, of refined copper, worth, say, $275,000,000. Shareholders have received in dividends $92,350,000 or about 35 per cent of the value of the output. It is estimated that the cost of production has been 8.2 cents per pound of copper. During 1906 the production should be close to 100,000,000 pounds and the dividends $6,000,000. Despite the great opportunity for financial games, the management has been consistently straightforward and honorable. The mine has been conducted as a sound business and in a conservative manner, the effect of which has been beneficial to the reputation of the copper industry of Michigan.

WHEN THE EARTHQUAKE OCCURRED a Japanese professor made calculations by which he ascertained its occurrence in place and time. We refer elsewhere to Mr. Omori's formula and we publish the substance of a lecture delivered by him here during the last few days. While he was at work at Tokio, Mr. Frederick L. Ransome, of the United States Geologlcal Survey, wrote an account of the probable causes of the earthquake a few hours after the news of it reached Washington, and this was prepared long before any facts were obtainable from the locality of the disturbance. And yet he also was enabled to make a scientific forecast, for, possessing an intimate knowledge of the geology of California, he knew her lines of structural weakness and placed his finger figuratively on the very fault along which the destructive slip occurred. A few days after the event we published an article by our Mr. W. H. Storms in which he described the earthquake line, correctly, as facts now show. His knowledge was based on data gathered while field-geologist on the staff of the State Mining Bureau. A former chief of that Bureau, Mr. A. S. Cooper, contributes a short article, with useful drawings, describing the now familiar earthquake line of California.

THE DISASTROUS EFFECTS of the earthquake upon the fine group of buildings comprising Stanford University are well worth careful study by the architect and student of structural engineering. The building scheme has been beautifully carried out in the so-called 'mission' style and the yellowish tinted veneer of sandstone with the pale red tiled roofs is picturesque in the extreme. The framing is generally of light wood and the main portion of the structure is of brick (in some parts of which railroad iron was used) laid dry, in mortar—not laid wet in cement. This is covered with slabs of the soft yellow sandstone mentioned, which is obtained near San Jose. This stone is a building material admirably adapted to the climate, though liable to scale and crack in countries where there is frost. The effect of the earthquake on this method of construction is shown by a photograph which we publish on another page. The same effect may be observed on a large scale in San Francisco at the City Hall and elsewhere throughout the neighborhood of San Francisco Bay. On the other hand, Robles Hall and the central block of the Museum and Art Gallery, both of which were built of tinted cement blocks, appear to have withstood the shock well. In some parts of the quadrangle and other places the work was done by day's labor and consists of solid stone; here the walls have stood better than the combination of brick with stone veneer—done by contract work. In many places the keystones of the arches along the corridors have slipped down, although the supporting pillars have apparently not spread. This could probably be obviated by designing the arch-stones of greater width, giving them a consequently greater keying power. The tower of the new library building is framed of structural steel and has remained intact, though the covering of masonry was demolished. Fortunately for the progress of education, few of the injured portions had as yet been occupied and there will be but little interruption to the classes at the University.

Bad Language.

We do not refer to profanity but to a scientific terminology that limits the usefulness of a geological pamphlet. It happens to be one of particular interest at this time, namely, the report of the Earthquake Commission. This report was prepared for the State of California at the instance of several scientific men and by order of the Governor. On the face of it, the report is intended to allay alarm and to explain to the public the scientific facts of the case. This is a laudable purpose. And the findings of the Commission are decisive. It did good work. But why in the name of common sense should a document intended for non-scientific readers be written in language that is needlessly and awkwardly technical? The first sentence of the actual explanation starts out with reference to "a line of peculiar geomorphic expression." The expression is as peculiar as the line; a 'peculiar topography' or 'an unusual earth-form' would have conveyed the same idea with much less of irritation to the average reader. Then mention is made of factors that will "contribute much to geophysical conceptions." The frequent use of "coseismal curves" and "fault scarps," without any explanation, is calculated to cause stumbling among laymen. All such terms are known to the scientific and they can be worried out with the help of a dictionary even by the average citizen, but here is a report, of unquestioned value and interest, prepared by first-rate men, and intended to allay the fears while ministering to the knowledge of the general public, and yet it contains a large number of technical terms, some of which are unnecessary, while others that are necessary appear without such explanation of their meaning as courtesy demands. It is a good example of the supercilious attitude of the scientific hierarchy We are reminded of an incident in a play called the 'Merry Monarch.' A lady

asks a foreign minister "What is this diplomacy you speak of so respectfully?" The reply is "If you did know what it meant, it would not be diplomacy."

Concerning the Earthquake.

On another page we publish the chief portion of the report of the Commission appointed to investigate the earthquake that led up to the San Francisco conflagration. It is calculated admirably to fulfil the purpose for which it was designed, namely, to allay the alarm based on popular misconception of the occurrence and to ascertain the immediate geologic cause of the disturbance. While the report is the work of a committee consisting of eight men, aided by capable assistants, it is obvious, from internal evidence, that it is to be credited mainly to Mr. A. C. Lawson, professor of geology in the University of California, who took the first steps that led to the appointment and subsequently organized the investigation. The report is signed by him, as chairman, and by Professor A. O. Leuschner, as secretary.

It is a conclusive contribution to science. The earthquake is proved to have originated along an old line of faulting which traverses the coast of California, and though the ultimate source of the movement must ever remain an obscure problem, the immediate cause is ascertained. The centre of disturbance was at the head of Tomales bay, 32 miles from San Francisco, but the shock was transmitted along a zone that follows an old fault for 375 miles. The maximum horizontal dislocation was about 20 feet, but over the 185 miles actually examined the surface movement averaged 10 feet. The vertical break was much less, the maximum observed being not more than four feet. Destructive effects extended for a distance of 25 to 30 miles on each side of the rift, although these observations are complicated by the possible occurrence of other lines of movement. The report does not refer to it, but it is likely that there was another rupture, traversing the eastern side of the Contra Costa hills, across Mare Island and through Sonoma county. The main line of disturbance, and the only one positively ascertained, cuts obliquely through the Santa Cruz mountains and is independent of such topography as it is due directly to ordinary erosion. It had been noted and described several years ago, for this reason. That is to say, it is the track of an old break in the earth's surface of a magnitude far exceeding the recent small slip and the movements which it marks must have been as much greater than the recent disturbance as a railroad collision surpasses the encounter of two persons in a crowd. The big fault originated far back in geologic time; it probably antedated man's first appearance and each succeeding movement involved intervals of time so great as to make human history an inadequate measure. Therefore, from a practical standpoint the proof of earlier disturbances and the suggestion of others yet to come, need cause no alarm, for it is the geologist who speaks, and he deals with time extravagantly. As to the effect on buildings, the Commission's report confirms the first inferences, which were those made on the occasion of previous earthquakes—and disregarded. Structures built on made ground or on alluvial soil suffered severely, because in such foundations the earth-waves are of maximum amplitude. If a jelly be placed in a porcelain bowl and if the latter be tapped, the vibrations pass through the highly elastic medium of the bowl in swift but minute waves that produce no apparent effect, but when they strike the jelly, their amplitude is enlarged and their period increased so that the jelly wobbles freely. A building on made ground behaves like a crumb perched on the jelly, but if piles be driven through the mud or gravel to the solid rock, then the building is anchored to the rock and moves with it—hardly at all. The same is true, with more assurance, of structures standing on the solid rock itself. It is the horizontal vibration that does the damage, the vertical component being slight and rarely destructive. On April 18 the vertical vibration was insignificant; the horizontal was about three inches in San Francisco itself. To most people even this seems wholly inadequate to account for the fearful result, but it must be remembered that the effect of each vibration of three inches becomes magnified by the acceleration of gravity, in other words, a pendulum motion is started, which may culminate, if the vibrations continue long, in a swing of a foot or more. The earthquake of April 18 was so destructive because it lasted a relatively long time—one minute and five seconds. The actual collapse of chimneys, copings, and structures in general, occurred toward the end of the second portion of the shock. Since the fateful day there have been many shocks, some of them severe, but all so short as to have done no harm. We presume that the final report of the Commission will be a volume, well illustrated with photographs, but it is not likely to add much to the essential facts as already given. No disturbance in nature producing great loss to humanity has ever been so quickly diagnosed or so successfully explained. And while man may justly pride himself on the quickening of his perception of the causes of things, he will remain humble in the face of his inability to ascertain the ultimate cause.

An Earthquake Formula.

Among the most interesting episodes connected with the scientific study of the recent disturbance in California, was the determination in Japan, by Mr. F. Omori, professor of seismology in the Tokio Imperial University, of the exact locality and time of the shock. This was done by an empirical formula, based on numerous observations of earlier earthquakes; the formula had been tested on several previous occasions, by its author, an acknowledged authority on the subject, and it had been printed eight years ago in the publications of the Earthquake Investigation Commission, of Tokio. Professor Omori's determination on this occasion was based on the record of his own seismograph at Tokio and the known fact that the length of the preliminary tremors indicates the distance of the point of observation from the place of origin of the earthquake.

We have Professor Omori's account of the calculations as published in Japan; as this is no place for them, we summarize by stating that the time the earthquake commenced at Tokio was 10 hr. 24 min. 35 sec. (Japanese time) on the night of April 18, the total duration being about five hours. The first preliminary tremors lasted 9 min. 49 sec., from which the approximate distance was calculated to be about 8,700 kilometres or, say, 5,400 miles. The actual distance from Tokio to San Francisco is 5,403 miles. By another formula he determined the time of the earthquake to have been 5 hr. 13 min. 5 sec., which many of us can testify to be an extraordinarily close approximation. The standard clock at the observatory of the University of California at Berkeley stopped at 5 hr. 12 min. 38 seconds.

The preliminary tremors represent those vibrations of small amplitude and short period which travel faster than the earth-waves that cause the heavy shocks; these smaller vibrations are also the ones that carry sound with them and while they originate at the same time, they travel so much faster as to precede the earthquake proper. At the Lick Observatory on Mt. Hamilton, the Ewing seismograph registered the introductory small movements for ten seconds, from which it is inferred that the central part of the great disturbance was at a distance of 80 miles. From Mt. Hamilton to the head of Tomales bay it is 83 miles. At the Berkeley observatory the Ewing seismograph was thrown out of adjustment by the violence of the shock, the magnitude of each component exceeding the range of the machine. The record of the preliminary tremors also is wanting.

Another feature is interesting. It appears that the first preliminary tremors were recorded at Tokio 11 min. 30 sec. after they were felt at San Francisco. As the direct spherical distance between these cities is 5,403 miles (as calculated from difference of longitude along an almost equal latitude), the velocity of propagation was 7.8 miles per second. On the other hand, at the observatory of the United States Weather Bureau at Washington, the preliminary tremors began at 8 hr. 19 min. 50 sec.; they were felt in Berkeley at 5 hr. 12 min. 6 sec., from which, after deducting the three hours difference between Eastern and Pacific time, it is apparent that they took 7 min. 44 sec. to travel the 2,413 miles to Washington, or at the rate of 5.2 miles per second. This appears to be a discrepancy, but it is not. The explanation would be highly technical; suffice it to say that the velocity of propagation varies with, or is a function of, the distance. At Washington the preliminary tremors lasted 5 min. 10 sec., as deduced by us from an examination of the printed seismographic record; taking this interval, the Omori formula gives an estimated distance of 2,443 miles from the place of earthquake origin; the measured distance being 2,422 miles. At London the shock was recorded twice and possibly three times, the first being that which was propagated along the shorter spherical distance, while the second was the vibration that traveled the other way around the globe; the third being the first after a complete circuit of the earth. Until recently it was believed that the vibrations took two paths, a shorter one through the earth, along the chord of the arc, and a longer one in a line parallel to the curved surface; but now the Japanese base their measurements on the latter, while the English seismologists, led by John Milne, stick to the first. At Tokio, Professor Omori records the vibration at 10 hr. 24 min. 35 sec. (Japanese time) as that which came direct along the shortest spherical route or minor arc, while another series of vibrations commencing at 31 minutes after midnight, or 2 hr. 6 min. 35 sec. later, he attributes to the vibration propagated along the major arc of the earth, from California southeastward through South America, the Atlantic and the Indian oceans, to Japan. Of course, the passage of these vibrations is affected by the composition or coherence of the rocks through which they pass, but over long distances there is a tendency to average, so that this perturbing factor becomes eliminated.

The test of scientific theory is prediction; Mr. Omori dates his 'Note on the San Francisco Earthquake' at Tokio on April 25, but we understand from him that his calculations were made before the cable had told him when and where the earthquake had originated. Therefore his was a notable achievement.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Limpid oil mixed with graphite is successfully employed as a lubricant on many bearings.

Alaska is now the winter home of many of the Far North adventurers, 3800 people remaining at Nome during the past winter.

A box 14 ft. long and 10 ft. wide, filled with ore to a height of five feet, or a pile of quartzose ore of these dimensions contains 35 tons.

The difference in length (not the total length) of a set of drills ranges from six to eight inches in starters, up to 18 in. to two feet in long drills.

During 1905 the railroads of the United States utilized 80,051,000 wooden ties. This should prompt the more extended use of metal or concrete ties.

Singulo-silicate is a term applied to certain slags wherein the ratio of the oxygen combined in the silica, is to the oxygen combined in the bases as 1 to 1.

In smelting copper ores, slags can be made which are high in silica, but the furnace will run more slowly, and if extreme care is not taken, a freeze will result.

The Buffalo and Susquehanna Iron Co. at Buffalo, use the gas from iron blast furnaces as fuel under their boilers, the steam being utilized in operating hoisting engines.

No place on earth is immune from earthquake. A short time previous to the Charleston earthquake, the city of New York was visited by a slight but very noticeable shock.

Fuller's earth consists of clay mixed with just enough fine silicious material to take away the plastic properties, so that it disintegrates into powder when mixed with water.

At Allentown, Pa., lime is burned with coke instead of with coal as is usually done in the East. Throughout the West most of the lime is made with various kinds of wood as fuel.

Argentite is silver sulphide, and should not be confounded with argentine which is a variety of calcite having a pearly luster, and slightly undulating surface. It is white, grayish or yellowish in color.

Earth, when first picked loose and shoveled into cars, occupies more space than it did in place, but when dumped and allowed to settle, it shrinks, and frequently takes less space than it did in place in the bank.

In some mines when contractors or lessees are at work, furnishing their own supplies, it has been found desirable for the company to issue to their days-pay men colored candles, which may be readily distinguished from other kinds.

There is no cohesion between wood and cement, and no dependence should be placed on such probability where strength is required. Concrete prevents the oxidation of iron and steel embedded in it, probably by excluding the oxygen of the air.

The toughest 'picking' ground is probably frozen clay. Rocks, such as tuffs, rotten granite, etc., too soft and friable to drill by the usual methods, may be bored with a suitable auger. A low-grade powder should be used in this kind of ground.

When figuring on concrete foundations, or walls, provide sufficient rock to completely fill the mould, counting nothing for the cement and sand. These latter fill the voids in the mass of broken stone and add nothing to the volume of the concrete.

It is seldom that ore picked up at random on a mine-dump can be relied upon to furnish an idea of the value of the vein. In the event of the ore in the vein being of uniform grade this might be possible, but it would be an unsafe means of information.

It is almost impossible to sink a shaft clear of a given sized set of timbers in blocky ground without numerous large excavations extending beyond the neat lines required. These should be filled with rock or timber placed back of the lagging, if the ground does not stand well.

Diamond drills have frequently been used in making connection between tunnels and higher flooded old workings. By this means the water may sometimes be removed from old works with safety and under control, where to make direct connection by drift or raise would result in disaster.

Phosphorescence in minerals is that property which causes them to emit light for some time after heating, exposure to light, or to an electrical discharge. Fluorite becomes phosphorescent upon being heated to about 150° C. Different varieties of the mineral give off different colors of light.

It is impossible to tell, even approximately, what the matte-fall in the furnace will be from a charge of certain composition without having had experience. Smelter men who are well up in their business can usually form a very fair idea; it is knowledge which must be gained by experience.

Machine-drill hose is wrapped with flat wire to protect the hose from damage likely to occur in its use underground, but few, if any, brands of hose will stand having machines thrown down on them, or withstand blasting. Careless miners occasionally subject air-hose to both of these strenuous tests of endurance.

The depth at which water may be obtained in desert dry lakes is impossible to anticipate. In a number of instances in California a good flow has been obtained between 80 and 100 ft. and occasionally at 20 ft. or even less, but in other cases the water-level is more than 100 ft. and in any event the water may be neither abundant nor serviceable.

An acetylene blow-pipe, in which oxygen is used with acetylene, has been invented. With its use a very high temperature is obtained, owing to the absence of inert nitrogen from the flame. It is claimed that with it a rod of pure iron serves as a soldering stick, and the heat is so great that a little of the carbon in the flame unites with the iron, converting it into mild steel.

In treating silver sulphides by the cyanide process, the finer the ore is ground the more quickly will the silver be acted on by the solutions. To grind fine is expensive. If fine grinding is not resorted to, the consumption of cyanide will be high and consequently expensive. Between these two evils the cyanide operator must find a happy medium, aiming to accomplish the best results at least cost.

The new slime-treatment plant of the Homestake Co. being built on the slope of McGovern hill, at Deadwood, will contain when completed, 26 large continuously operating filter presses. In this plant it is expected to treat 1800 tons of auriferous slime daily. Heretofore the greater part of this material has been utilized to sluice out the sand from the large vats in the works at Lead and Gayville, and it has flowed to waste with the tailing. This slime, containing less than $1.50 per ton, will be treated at a profit.

Much time is often unnecessarily lost in trying to recover a fitchered hole in drilling with machines. If after two or three trials and careful running the hole cannot be reamed out, and drilling proceed as before, it is generally better to abandon the hole, and start another. Ordinarily holes do not fitcher until deep enough to be of some service in blasting the round. Occasionally a badly fitchered hole may be finished by substituting a chisel-bit drill for the ordinary cross-bit.

Recent extensive investigation of underground temperatures in the mine workings and bore holes on the Rand, South Africa, have demonstrated that the increase of temperature is one degree for each 208 ft. Starting from a mean temperature of 68.75° at 1000 ft. depth, the following was deduced: 1000 ft.=68.75°; 2000 ft.=73.55°; 3000 ft.=78.35°; 4000 ft.=83.15°; 5000 ft.=87.95°; 6000 ft.=92.75°; 7000 ft.=97.25°; 8000 ft. =102.35°. All temperature measurements are Fahrenheit. Good ventilation in mines always has a tendency to reduce the temperature, both of the workings and of the rocks themselves. These measurements have been taken in a region where little metamorphism has occurred, and where there are no large masses of decomposing rocks, such as those on the Comstock Lode of Nevada where high temperatures are common at comparatively moderate depths.

When it is the intention to close down a mine for an indefinite period it is a wise thing to place a substantial platform in the shaft some distance below the collar, and preferably at the natural water-level. In the event of the upper portion of the shaft caving, the debris may fall no further than the platform, which will result in a great saving in case it is desired to re-open the mine.

It has been learned by experience that it is unwise to set the battery-posts of a stamp-mill directly upon concrete mortar-blocks, as the posts in a few months become somewhat rounded from the constant vibration and slight impact, so much so as to ultimately seriously interfere with the running of the cam-shaft. A piece of heavy timber must be placed flat on the concrete block, and between it and the lower end of the post.

Owing to uncertainties which may be encountered in shaft-sinking, miners, though willing to sign a contract to sink a shaft, with the proviso of a forfeit in the event of non-fulfilment of contract, are unwilling to give a bond for the completion of such work. Shaft-sinking, and most other mining work is wholly different from building and similar construction which is frequently undertaken on contract. In the latter, the factors are known and are constant, or nearly so, but in mining work the element of uncertainty is too great to make it safe to take contracts under bond.

The steel wire spirally wound inside the suction hose of a mine pump is to prevent collapse of the hose from atmospheric pressure when the pump is in action. The hose should be wrapped on the outside throughout its entire length with Manila rope at least ⅝ in. diameter to protect it from possible injury from flying rock, when blasting, and when pumping to prevent abrasion from contact with timbers or rocks, which would result in cutting a hole through the hose, if not protected in some manner. It is also a wise precaution to suspend the hose by ropes that it may touch nothing below the pump when pumping, thus still further minimizing the danger of abrasion.

When the character of the ground, or of the shaft itself, when sinking, is such that timbers must be carried close to the bottom, damage to the timbers from blasting may be averted to a great extent by employing fenders underneath the wall-plates. These may be made either of green timbers, or of soft steel plates bent to fit the front and bottom of each plate. Either the timber fenders or steel plates are secured to the shaft-timber set by suitable bolts having solid square heads, which pass upward through the unoccupied hanging-bolt holes in the plates. This precaution not only saves the timber from being cut and slivered, but may also prevent its being broken. The scheme here proposed has frequently been employed with satisfactory results.

It is part of the duty of the shift-boss or the foreman to know how long his muckers should take, and how long they do take, to fill a car by shoveling, and how many cars per man per shift of both waste and ore are sent to the shaft, or out of the tunnel. Not only this, but he should know how long trammers loading from chutes usually take to fill their cars. If stoppages are frequent owing to large pieces of ore jamming in the gateway, the fault lies, not with the trammer, but with the miners in the stope above, and it should be seen that no large pieces are thrown into the mill-hole. There are many small things happening constantly in the mine, things little in themselves, but which in the aggregate are material in the item of cost. Among these are the frequent derailing of loaded cars. If this occurs more than once at the same place the fault probably lies in the track, which should at once be fixed so as to prevent the recurrence of a similar trouble. It pays to put in good tracks and to keep them clear. It is poor business to keep three or more shovelers waiting from two to five minutes for a car, for if this occurs at all, it is likely to be repeated every 15 to 20 minutes, depending on the number of shovelers. Avoid long waits, they are expensive and demoralizing.

The Probable Cause of the San Francisco Earthquake.

By Frederick L. Ransome.

Most authorities on earthquakes distinguish two main classes—(1) volcanic quakes and (2) tectonic, or dislocation, quakes. The former originate in districts of active vulcanism and at comparatively shallow depth. According to Major C. E. Dutton, the greater number of such shocks are initiated at depths less than two miles. They are characterized by a fairly definite centrum, a relatively short radius of influence, and the absence of subordinate after-quakes. They are phenomena that could probably be closely imitated by the explosion of a large quantity of dynamite at the bottom of a deep mine. Tectonic quakes, on the other hand, may originate at greater depth; they usually have indefinite or elongated centra they are characterized by a greater radius of activity, and the main shock is usually followed by after-quakes. Most of the great destructive earthquakes recorded in history belong to this class. Such, for example, was the Mino-Owari earthquake in Japan, which in 1891 killed over 7,000 people, wounded over 17,000 more, and destroyed more than 200,000 houses. This quake was plainly caused by movement along a fissure which appeared at the surface as a fault about 70 miles long, with a maximum throw of 20 ft. Prof. John Milne, after an exhaustive study of the seismological records of Japan, concluded that shocks are most frequent in districts that exhibit evidence of elevation or subsidence still in progress.

Four kinds of waves are generated in most earthquake shocks: (1) normal waves, (2) transverse waves, (3) surface waves, and (4) epifocal waves. The first three depend upon the elasticity of the rocks traversed, are not visible, and although propagated with different velocities, are not always distinguishable. The last are the visual waves, resembling, as Major Dutton says, flat waves on water. They are characteristic of the epicentral tract of many great earthquakes and are highly destructive. They bear no clear relation to elasticity and result from the passage of the deeper waves from an elastic medium (solid rock) into a feebly elastic medium, such as soil or unconsolidated sediments. They thus account for the ruin often wrought in valleys and in low ground when structures on near-by hills escape.

The frequency of earthquakes in California is well known, and tremors sufficient to rattle the windows of dwellings in San Francisco have in the past been so common as to excite little alarm and arouse but passing interest. The number of quakes recorded in San Francisco from 1850 to 1886 is 254, and 514 additional shocks were noted in the same period in other parts of California. They are undoubtedly more prevalent in the region surrounding the Bay of San Francisco than in the northern or southern extremities of the State. While most of the southern quakes have effected no damage, others, such as the great shock in 1868, which injured San Francisco, the Owens Valley earthquake in 1872, the Vacaville earthquake in 1892, and the Mare Island earthquake in 1898 were notably destructive. In general, it may be said that the earthquakes in California exhibit the features characteristic of tectonic quakes, and the Owens Valley shock is generally ascribed to movement along the great fault limiting the Sierra Nevada on the east.

A section across central California, say, from Monterey bay to Mono lake—shows three well-marked topographic divisions. On the northeast is the gentle western slope of the Sierra Nevada, about 70 miles broad, which rises gradually from the eastern edge of the main interior valley to the crest of the great scarp overlooking the deserts of Nevada. The range is essentially a huge fault-block composed of Jurassic and older rocks and partly covered by Tertiary lavas.

The Great Valley is in the main an alluvial plain 50 to 60 miles wide, its northern part drained by the Sacramento river and its southern part by the San Joaquin. Both streams flow into the head of Suisun bay and their waters find their way across a depression in the third topographic division, the Coast Range, through San Francisco bay and the Golden Gate into the Pacific.

The Coast Range separates the Great Valley of California from the Pacific ocean. It comprises numerous nearly parallel ridges separated by narrow alluvial valleys and constitutes a generally mountainous belt 60 miles in width. Both in lithology and structure it presents a marked contrast to the Sierra Nevada, although the relations of the two ranges in the northern and southern parts of the State are not as yet fully understood.

The oldest rocks known in the Coast Range are limestones and quartzites, with some crystalline schists, and are exposed at various localities from Point Reyes, north of San Francisco, to San Luis Obispo. These rocks, which are probably Paleozoic, are cut by granite supposed to be of the same general age as the main granitic intrusions of the Sierra Nevada, which are known to be post-Jurassic. All of these rocks, after being above sea-level long enough to be extensively eroded, were submerged and were covered by a series of sediments several thousand feet thick, known, from its characteristic development at San Francisco and on the north side of the Golden Gate, as the Franciscan, or Golden Gate series. Although the Franciscan consists mainly of sandstone such as forms the well-known Telegraph Hill in San Francisco and the larger islands in the bay, it contains also some of the most interesting and characteristic rocks of the Western coast, such as the serpentines, the blue glaucophane schists, with their wonderful mineralogical variety, and peculiar jaspery rocks made up in part of the silicious skeletons of radiolaria. The age of the Franciscan series, which forms a large part of the Coast Range, is still open to question. It is thought by some geologists to be Jurassic, by others to be early Cretaceous.

The deposition of the Franciscan sediments was ended by an upward movment of the sea bottom. They were folded and faulted, lifted above sea-level and eroded by streams and waves. Again, however, the land went down, the Franciscan rocks sank beneath the sea and were covered by thousands of feet of fossiliferous Cretaceous, Eocene, and Miocene deposits. The sediments of the last period alone attained a thickness of over 8,000 ft. At the close of the Miocene and after minor oscillations of level the rocks were again raised above sea-level and were crumpled and faulted by the energy of the uplift until they formed a well-defined range separating the ocean from the interior valley. In Pliocene time the land again subsided, although the Coast Range was probably not wholly submerged, and marine deposits of this period were laid down in sounds or inlets.

Here belongs the San Pablo formation, a thick accumulation of sandstone with intercalated volcanic tuffs. Apparently during the later stages of San Pablo deposition new movements of the land took place whereby fresh-water basins were formed, in which accumulated over 3,000 ft. of sediments and lava flows—the Berkeleyan and Campan series of Professor Lawson. Nor is this all. Still later in the Pliocene was deposited the Merced series, which is exposed along the ocean beach west of San Francisco. This remarkable deposit, described and named by Professor Lawson, is a mile in thickness and has at its base the well-preserved remnants of a coniferous forest. Thus a portion of the Tertiary land upon which pines, indistinguishable from the species now growing at Monterey, sank beneath the waves to a depth of at least 5,000 ft., and so rapidly that the trees were buried under sediments before they could decay. Finally the Merced series, carrying in its upper beds fossils of Quaternary age—the mere yesterday of geological time—have been elevated above the sea, tilted up at angles as high as 75°, and dislocated by a fault of at least 7,000 ft. throw.

If anyone will look at a good map of California he can scarcely fail to notice the striking parallelism of structure shown by that part of the State lying north of Tulare lake and south of Red Bluff, near the head of the Sacramento valley. This parallelism is not confined to the two main ranges, the Great Valley and the coast line, but is conspicuously shown by the ridges and valleys of the Coast Range. In the absence of local geological knowledge, this feature of the topography might be ascribed to regular folding, such as that of the Appalachians. The actual complexity of the folding, however, and the fact that the structural details of the ridges show little accord with the general topographic regularity referred to, dispose effectually of this suggestion. There can be little doubt that the principal longitudinal ridges and valleys of the Coast Range are due to faulting modified by erosion. Much detailed work remains to be done before the positions and throws of all these faults can be determined, but such careful structural studies as have been made of definite areas have invariably revealed the great importance of dislocations having a generally north-northwest trend. This is particularly true of the San Francisco peninsula, which, as Prof. Lawson has shown, is traversed by at least three great faults belonging to this dominant system. These have been plotted on the accompanying outline map of the region about San Francisco bay and relief map of the peninsula. The San Bruno fault has a throw of at least 7,000 ft. near San Francisco, the southwest side having dropped relative to the northeast side. In all probability this same fault determines the positions of Bolinas and Tomales bays, north of the Golden Gate, and the straightness of the coast line as far as Point Arena, 100 miles northwest of San Francisco. Toward the south the same fault, or one belonging to the same zone, is said to be traceable almost to the Gulf of California, and in parts of southern California, is locally known as "the earthquake crack." The San Andreas fault, which, as may be seen from the small relief map, is followed by a rectilinear ravine occupied by a chain of ponds and lakelets whose existence is proof of recent disturbance. The third, or Pilarcitos, fault has not impressed its presence upon the topography of the peninsula in so conspicuous a manner as the other two. It is highly

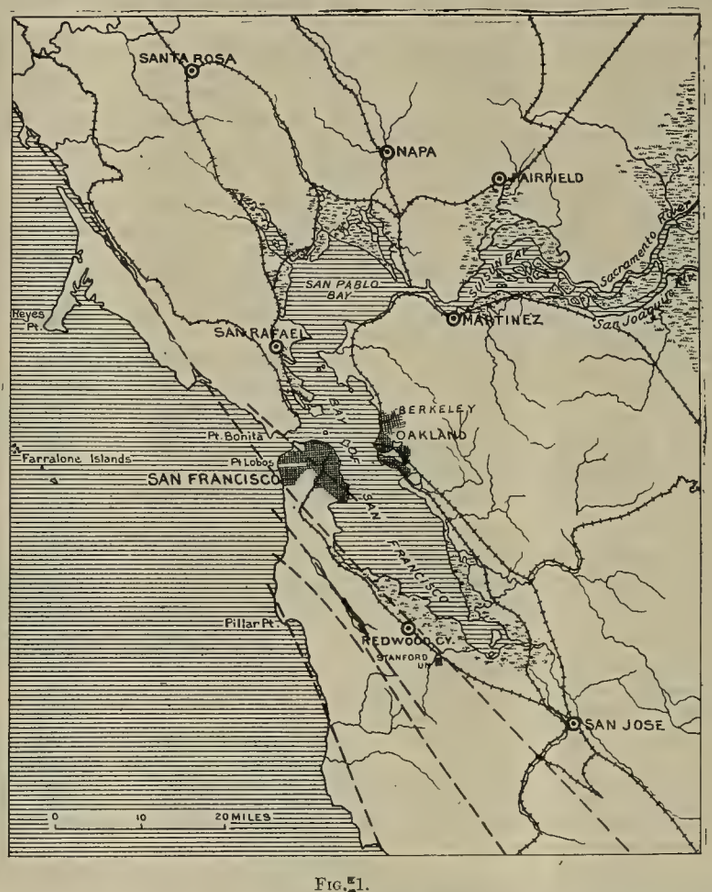

Fig. 1.

probable that future careful work will discover other great faults generally parallel with those mentioned. There is a strong suggestion, for example, of a fault passing near San Jose, along the eastern margin of the bay (see Fig. 1), through Santa Rosa, and northwestward along the valley of the Russian river past Ukiah. *

Another Earthquake Theory.

In 'Popular Science Monthly' there is an important article, taken from the London 'Times,' and written by Mr. H. H. Turner, professor in Oxford University, dealing with earthquakes. Professor Turner says:

Professor Milne, in the tenth report of the British Association committee, refers the 'world-shaking' earthquakes observed in the six years 1899-1905 to thirteen great earthquake regions, designated by the first thirteen letters of the alphabet. Three of these, I, J. and L, are responsible for only five, three and two shocks respectively, and are thus of small importance compared with the others, which average about forty shocks each. Excluding them for the present, the remaining ten regions lie approximately in two rings on the earth's surface, a configuration which is most strikingly apparent when the regions are marked on a globe. The more important ring includes the following seven regions: A (Alaskan coast), B (Californian coast), C (West Indies), D (Chilian coast), M (South of New Zealand), F (Krakatoa region), E (Japan). Its centre is among the conspicuous group of islands which includes Tahiti, and the radius of the ring is about 65 degrees. The other ring has its centre at the opposite point of the earth, which is in the Sahara desert; and at a radius of 50 degrees from this centre lie regions G (between India and Madagascar), H (the Azores) and K (Tashkend). Now, this is not merely a convenient geographical summary, but a physical fact of vital importance, according to recent researches by Professor Jeans. In a remarkable paper read before the Royal Society in 1903 he gave reasons for believing that the earth is by no means a sphere or a spheroid, as we have been accustomed to think, but is of a pear-shape. Under gravitational stress it is continually approaching the spheroidal form, the pear is being crushed into a sphere by its own attraction; and the result is a series of earthquakes. These naturally occur in the weakest places, and if any one will experiment in crushing a pear towards a spherical shape, or even draw a diagram and consider where the weakest points would be, the reasons for the existence of two rings of greatest weakness will readily suggest themselves. The ends of the pear are the centres of these rings, one in Africa, one in the Pacific; and when once this is pointed out, the pear-shape of the earth is, according to Professor Sollas, 'obvious to mere inspection; it is a geographical fact and not a speculation.' Professor Sollas is indeed responsible for the particular suggestion above sketched; for Professor Jeans had originally proposed a different axis, which he withdrew in favor of the obvious improvement. The confirmation of Professor Sollas' view from the distribution of earthquake centres is remarkable. It does not seem, however, quite certain which is the blunt end of the pear; it has been hitherto placed in Africa, but there seem to be several reasons for regarding Africa as the stalk end. This point cannot, however, be dealt with here. The important thing is that there seems to be a real reason for the occurrence of earthquakes in these particular regions, and that they will probably continue to occur there. Professor Jeans' conclusions have recently been examined by Lord Rayleigh, who announced at the Royal Society only a few weeks ago that he found them generally confirmed, and that we must regard our earth as at present in a state far from stable.

We come to the second point, the distribution of earthquakes in time. Are there seasons of special activity such as the recent occurrence of several disasters seems to suggest? Here our knowledge is slighter still, and the observed facts have not yet been co-ordinated by a mathematical investigation. Still there seems to be some evidence in support of the view that exceptional irregularities in the rotation of our earth may be responsible for an increased number of earthquakes at particular times. That the evidence is slight must be attributed to the shortness of the time during which it has been possible to obtain it, and not necessarily to inherent weakness in the evidence itself. The brevity of the earthquake record has been mentioned above; that of irregularities in the earth's rotation is longer; but the discovery that such irregularities existed was made only twenty years ago

*Abstract from the current issue of the 'National Geographic Magazine.'

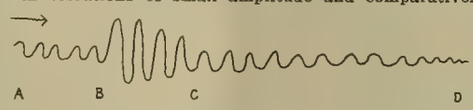
Observations of Distant Earthquakes.

Written for the MINING AND SCIENTIFIC PRESS by F. OMORI.

The motion of an earthquake consists of several sets of vibrations, the amplitude and period of which differ widely. It is convenient to divide this motion into the sensible or macro-seismic, namely, that which can be felt as tremblings or shocks; and the insensible or micro-seismic, which can not be felt. In the former, quick vibrations co-exist with slower ones, while in the latter quick vibrations are either absent or extremely minute. Some of the vibrations in the insensible motion are as large as those that are felt in local earthquakes; they are insensible only because their period is long and, consequently, their acceleration small; the lowest acceleration of the sensible motion being about 17 mm. or 0.67 in. per sec. The waves of quick period and short length are dissipated with increase of distance from the center of disturbance, more rapidly than the slow and long waves; the result being that the motion due to a distant earthquake is simpler in character than that due to a near one; it is entirely micro-seismic or insensible. By a "distant earthquake" is meant one whose epi-central* distance from a given station is at least 2,000 km. or 1,200 miles.

The earth's crust may be regarded as an elastic medium through which seismic waves are propagated. They are recorded and measured by the seismograph, a modern instrument of extreme sensitiveness. By the aid of it we can observe a great earthquake in any part of the world, the motion due to such a disturbance lasting generally from one to five hours.

Near Earthquakes. In an ordinary earthquake, the motion, as observed with a seismograph, begins always with vibrations of small amplitude and comparatively



A B. Preliminary tremors.
B C. Principal part.
C D. End portion.

short period. These are known as the 'preliminary tremors' and last from a few seconds to a few minutes; next come those of large amplitude, constituting the 'principal' part; and finally the earthquake ends with feeble movements. When the origin of the disturbance is near to the observer, a sound resembling distant thunder or a rushing wind is heard just before the arrival of the ground-trembling. These sound phenomena, which are of frequent occurrence in a rocky district, but rare on the plains, are credited to the rapid vibrations existing in the 'preliminary tremor'. The fact that animals show signs of disquietude just before an earthquake, is probably due to their acute senses, enabling them to feel the first movement of the preliminary tremors. The duration of the preliminary tremors does not depend on the magnitude of the earthquake; on the contrary, it varies with the radial distance. Thus, if Y denote the duration (in seconds) of the preliminary tremors of an earthquake at a place, whose distance (in kilometres) from the origin of disturbance is X, we have the following empirical equation:

$$X = 7.27Y + 38$$

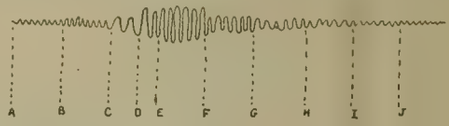
which is to be used for values of X between 100 and 1,000 km. This equation enables us to estimate, from the diagram taken by a sufficiently sensitive seismograph, the distance of the earthquake origin. And if the seismograph records be simultaneously taken at two or more stations, we can determine the approximate position of the origin. As an example, I refer to the excellent Ewing seismograph record taken by Dr. Campbell at the Lick Observatory. According to that seismogram, the preliminary tremor on April 18 lasted about 10 to 12 seconds, from which it may be inferred that the central part of the great disturbance was at a distance of about 120 km., or 75 to 80 miles, from Mount Hamilton.

The duration of the strongest part of the principal portion of the vibrations ordinarily varies between 4 and 10 seconds, but in cases of destructive disturbance, it reaches 30 seconds or more. From the Lick Observatory seismogram, the duration of the principal portion in the recent great shaking seems to have been about 40 seconds..

In slight earthquakes, the movement of the ground is small, a mere fraction of an inch. When the motion reaches half an inch, the earthquake becomes strong and may cause damage. When, however, the motion extends into inches, the effect is destructive, and ordinary brick houses, chimneys, etc., succumb. The motion in the strongly shaken parts of San Francisco was probably three inches.

In ordinary cases, the vertical component of earthquake motion is much smaller than the horizontal, being, even when greatest, unable by itself to produce serious damage. In fact, in this regard the vertical component is only of secondary importance; in other words, the seismic damage to structures may, with rare exceptions, be regarded as due wholly to the horizontal motion.

Distant Earthquakes. A careful examination of seismograms shows that the motion consists of several phases, in each of which the period remains essentially constant, while the amplitude is also on the whole constant, except for the occurrence of maximum and minimum groups.



Diagrammatic Representation of the Earthquake Motion Proceeding from a Distant Origin.

a b. First preliminary tremors.
b c. Second preliminary tremors.
c d. First phase of the principal portion.
d e. Second phase of the principal portion.
e f. Third phase of the principal portion.
f g. Fourth phase of the principal portion.
j. End portion.

The successive phases of the earthquake motion, illustrated in the figure, are as follows:

The 'preliminary tremor,' which consists of vibrations of small amplitude and of short period, is divided into the earlier portion or the first preliminary tremor, and the later portion or the second preliminary tremor. Commencement of the latter is marked by an increase of amplitude and, in many cases, also by the appearance of slow undulations.

The 'principal portion' denotes the most active part of an earthquake, and consists of movements of larger amplitude. The earlier part is further subdivided into three successive stages as follows: (a) The first phase, consisting of a few very slow movements; (b) the second phase, consisting of slow movements, whose period is generally shorter than in the first phase; (c) the third phase, consisting of vibrations of a period much quicker than that in the preceding two phases. The third phase is followed by others of small amplitude. In earthquakes of near origin, the motion, on account of the existence of quick vibrations of macro-seismic character, is much more complex than in distant earthquakes, and it becomes difficult to subdivide the principal portion into the different phases.

Lastly, the 'end portion' denotes the feeble finishing part of earthquake motion.

As in the case of near earthquakes, the duration of the preliminary tremors at a given place is found to depend on the distance from the origin: Thus let X denote the arcual distance* (in kilometres) between the epicentre and the observing place, and Y the total duration (in seconds) of the first and second preliminary tremors, then we have the following empirical relation:

$$X = 6.54Y - 720$$

which has been deduced from the observation of different earthquakes when X varied between 2,000 and 14,000 km. Again, if Y_1 denote the duration in seconds) of the first preliminary tremor, X having the same signification as before, we get the following formula:

$$X = 17.1Y_1 - 1360$$

Each of these equations may be used for determining at once the distance of an unknown earthquake, from the record taken at any given place.

The time (T) of occurrence at the origin of any distant earthquake may approximately be calculated, from the seismographic record, by the following empirical formula:

$$T = t - 1.165Y$$

where Y has the same meaning as before, and t denotes the time of earthquake occurrence observed at a given place.

Pulsatory Oscillations.—Before going further, let me refer to a phenomenon called 'pulsatory oscillations.' These are small and slow pulse-like movements that are not of earthquake origin; they denote the fact that the ground is in a state of vibration even when there is no earthquake at all. As the period of these pulsatory oscillations varies but little, and remains constant for several successive hours, it may be supposed that they represent the proper vibrations of certain portions of the earth's crust, such for instance as the plain of Musashi on which Tokio is situated. The different por-

*The epi-centrum is the point on the surface vertically above the place where the earthquake originated.—EDITOR.

*(That is, as measured along the curvature of the earth, or the arc-distance.)

tions of the earth's crust appear to be in continual movement, and the period of some of these vibrations ought to be determinable in each case from the geotectonic circumstances of the locality. For instance, a careful examination of the horizontal pendulum diagrams obtained at Tokio shows that the pulsatory oscillations are essentially vibrations with a period of about 4 seconds, more or less mixed up with those of a period of about 8 seconds. The vibrations of 4 seconds' period occur frequently, but cases are not wanting, where the vibrations of the 8 seconds' period predominate. Again other cases occur, in which the two kinds of vibrations are recorded in different parts of one and the same diagram. The average values of the periods of these two series of vibrations are respectively 4.4 seconds and 8 seconds. We may perhaps assume that the 8 seconds' period vibration constitutes the fundamental oscillation proper to the Tokio plain, the 4 seconds' period being one of its harmonics.

The average period of the principal pulsatory oscillations at Osaka, Formosa, Gottingen, and some other places, is either nearly 4 seconds or nearly 8 seconds. It may be that the period (or periods) of the pulsatory oscillations is approximately constant all over the world.

Pulsatory oscillations generally accompany a cyclone; the effect of a great atmospheric depression being sensible at a distance of several thousand kilometres. In a few cases, however, pronounced storms of pulsatory oscillations occur on days when calm weather prevails all over Japan. In Tokio, earthquakes occur rarely while pulsatory oscillations are active. On the other hand, shocks are frequent when these oscillations come to a state of minimum activity.

Periods of Earthquake Vibrations. The predominating periods in the preliminary tremors of the distant earthquake motion observed at Tokio were those of about 4.5 and 8.5 seconds, corresponding thus with the pulsatory oscillation. Moreover the periods observed in the preliminary tremors do not depend on the distance of an epicentrum from the observing station, nor upon the nature of the disturbance at the seismic origin, but they are characteristic of a particular region—in this case Tokio. A similar conclusion probably holds good also for the periods in other stages of the earthquake motion. The conclusion is that the principal vibrations in the preliminary tremors of distant earthquakes and the pulsatory oscillations are identical phenomena.

The explanation is as follows: The waves of the preliminary tremors are transmitted along a deep layer of the earth's crust with a velocity (about 14 km.) of which I shall speak presently, and communicate a stress to the superincumbent surface layer of the earth's crust in the region about the observing station; the latter being, in consequence, thrown into its own proper vibrations. Thus, the preliminary tremors are nothing else than the pulsatory oscillations, caused by the waves transmitted along a deep layer of the earth's crust from the origin of an earthquake.

The Velocities of Propagation of the Vibrations. In calculating the velocities of propagation of distant earthquake waves, it makes a great difference whether we suppose the waves to be propagated along the chord of the earth (joining the origin to the observing station) or parallel to the surface. Calculated on the latter supposition, which seems to be more probable, the velocities of the different waves of the earthquake motion come out approximately the same, irrespective of the arcual distances, those cases, in which the epicentral distance is small, say, under 30°, being excluded. On the chord supposition, the corresponding velocities come out quite different, according to the distances.

If we denote by V_1, V_2, V_3, V_4, V_5, V_6, V_7, and V_8 the velocities of propagation (supposed parallel to the earth's surface) of the waves at the commencement of the successive phases of the earthquake motion, their mean values are as follows:

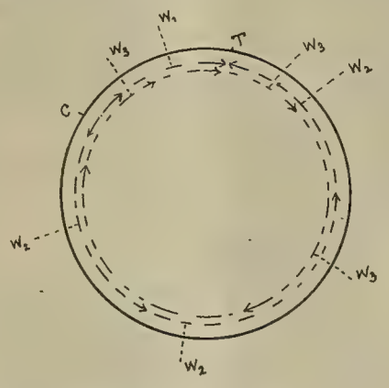
V_1	13.7	km. sec.	V_5	3.3	km. sec.
V_2	7.2	"	V_6	2.8	"
V_3	4.6	"	V_7	2.4	"
V_4	..	"	V_8	2.1	"

Now the velocity of propagation of the vibrations at the commencement of the principal portion of a near earthquake is 3.3 km. (or two miles) per second, which is the same as V_5 above. Here it is evident that the vibrations in the 3rd phase of the principal portion are transmitted along the surface of the earth's crust.

The transit velocity of the vibrations of the 1st preliminary tremor, namely V_1, is very great and no known rock has an elastic modulus sufficiently large to permit of it, whether the vibrations be longitudinal or transverse. Hence we must conclude that the waves of the 1st preliminary tremor are transmitted along some path within the earth's crust. As, however, the duration of the 1st preliminary tremor at a given station is very nearly proportional to the arcual distance between the station and the earthquake origin, it seems likely that the waves of the 1st preliminary tremor are transmitted parallel to the surface of the earth and at a constant depth below it; the supposition being that the waves of the 1st and 2nd preliminary tremors and of the principal portion are all generated simultaneously at the earthquake origin, becoming gradually separated from one another (on account of the difference of the transit velocities) as the disturbance extends. The layer along which the high velocity (V_1) waves are propagated may mark the limit beyond which the seismic waves are, on account of certain physical properties of the underlying medium, unable to penetrate; or there may be, as Professor Nagaoka suggests, a maximum transit velocity. A rough calculation, based on the relation of the duration of the 1st preliminary tremor and the epicentral distance, and on the value of the different velocities, gives 600 kilometres or about 400 miles as the probable depth of the layer along which the vibrations of the 1st preliminary tremor are propagated.

It is probable that the waves having velocities V_2 and V_3 are transmitted along layers at smaller depths within the earth's crust.

Propagation of the Seismic Motion Completely around the Earth. Let T be the observing station and C the earthquake origin. Then there are three sets of motion, which can be distinguished; they may be denoted respectively as W_1, W_2, and W_3.



The W_1 waves are those propagated from C to T along the shortest path, parallel to the surface, namely along the minor arc; the W_2 waves are those propagated from C in the opposite direction and arriving at T after passing through the antipode of C, namely, along the major arc; and the W_3 waves are the W_1 waves which are propagated beyond T in the same direction, and again arrive at T after making one complete circuit of the earth.

The identification of the W_3 waves is possible only in a few cases; that of the W_2 waves is, however, more definite, being characterized by the fact that their period is much slower than those of the preceding vibrations, which form the end portion of the W_1 waves.

The average period of the W_2 waves is, with a few exceptions, uniform and gives a mean value of 20.4 seconds, which is identical with the predominating period in the 3rd phase of the principal portion; the period of the W_3 waves is also nearly the same as that of the W_2 waves. These facts seem to indicate that the W_2 and W_3 waves are the same as those which constitute the 3rd phase of the principal portion of the earthquake proper.

The time interval between the arrival of the W_1 and of the W_3 waves is 3 hr. 20 min. 46 sec.; this agrees with the time that would be taken by the vibrations in the 3rd phase of the principal portion in making one complete circuit around the earth, with the velocity of 3.3 km. or two miles per second.

The San Francisco Earthquake Observed in Tokio. The time of commencement in Tokio of the earthquake was 5 hr. 24 min. 35 sec. a. m. (Pacific time); the total duration of motion being five hours. The duration of the 1st preliminary tremor was 9 min. 49 sec., from which the approximate arcual distance between the origin of the earthquake and the observing place was calculated to be 5,400 miles, and the time of the occurrence at the origin of the shock to be 5 hr. 13 min. 5 sec. a. m. (P. T.).

The 1st displacement of the well-defined horizontal vibration at the commencement of the 2nd preliminary tremor was directed toward S 27° W; the counter displacement being directed toward NE. It will be observed that the directions of these movements correspond to the great circle joining Tokio with the origin of disturbance.

At 7 hr. 31 min. a. m. (P. T.), or 2 hr. 6 min. 35 sec. after the commencement of the disturbance, there began vibrations which correspond to the same earthquake motion propagated along the major arc of the earth, that is, from the center in a southwestern direction, through South America, the Atlantic, and the Indian Oceans.

As other examples of large earthquakes which disturbed the west coast of the American continent, I may mention the following: The Alaska earthquake of September 3 and 10, 1899, and on October 9, 1900; Central American earthquakes, on April 18 and September 22, 1902; Panama, Colombia and Ecuador earthquake, on January 1, 1906.

The whole Pacific coast, which forms one of the most active seismic districts in the world, is frequently visited by earthquakes of different size and intensity. Large destructive earthquakes have, however, a tendency to happen in groups, that is, they occur along different parts of a given zone in the course of a few years. Thus, as mentioned above, there were, between September 1899 and January 1906 a series of six extensive disturbances which affected the whole coast from Alaska down to South America, indicating that these earthquakes were of no local character, but that there was great stress along the Pacific border, such as to lead one to expect the extension of the seismic disturbance to California. The great earthquake of April 18 last may therefore be regarded as having completed the continuity of the manifestation of the seismic activity along this part of the world. Now, the earthquake is caused by the existence of a weak point underground, which, reaching the limit, finally gives rise to a sudden disturbance that becomes the source of the wave motion that is propagated through the rock and the soil. An extensive earthquake such as that of April 18, may be regarded as having removed the instability existing in this part of the earth's crust; those regions most violently shaken becoming seismically the safest place for a certain interval of time. As a matter of fact, there is no case recorded in which great earthquakes have originated successively at one and the same center. The small after-shocks which will continue to shake the western coast for a few years, are not of a dangerous nature. On the contrary, it is absolutely necessary that these small shocks should occur, as they enable the disturbed earth's crust to settle into a condition of equilibrium.*

Iron.—The element iron, as well as the rest of the so-called true metals, is considered as having but one atom to the molecule. If we heat iron, the motion of its atoms becomes greater and greater and their attraction for each other less and less, until, finally, their coherence is so far overcome that the iron melts. In this state the individual particles are able to move freely about one another, but their coherence has not been completely destroyed. When iron is far below the melting-point, a definite amount of heat is necessary to produce a certain rise in temperature for each unit by weight of the iron. This amount is, approximately, the same for each degree of rise in temperature until the iron begins to soften. Above that point, the amount of heat necessary to raise the temperature of the iron one degree becomes greater and greater until the iron melts. This extra amount of heat produces no perceptible rise in temperature. It is absorbed by the iron and becomes, in fact, latent heat. The heat so absorbed serves to give a greater motion to the atoms, and this being converted into motion is no longer perceptible as heat. When the iron solidifies, this motion is again transformed into heat, which prolongs the cooling of the iron. When sufficient heat has been applied to the iron to melt it, it becomes a liquid, and as such is subject to the laws which govern liquids. In a liquid the particles are free to move around and about one another, but their coherence has not been completely overcome. A liquid is capable of dissolving many substances, and iron in a liquid state acts as a solvent, and as such follows the laws governing solutions. It is upon the substances thus dissolved by iron, and existing in it as impurities, that the commercial value of iron depends. There are a number of these dissolved substances, each playing its part in the formation of the varying conditions of commercial iron. The most important, in fact, the all-important, substance is carbon.

Bare copper wire is sold wholesale at an advance of about 1¼c. to 1½c. per lb. over refined copper ingots.

---

*(This paper forms the substance of a lecture delivered before the Astronomical Society of the Pacific, at the University of California, on June 9, 1906. Reported and abstracted by the Editor.)

Report of the State Earthquake Commission.

One of the remarkable features of the Coast Ranges of California is a line of peculiar geomorphic expression which extends obliquely across the entire width of the mountainous belt from Mendocino county to Riverside county. The peculiarity of the surface features along this line lies in the fact that they are not due, as nearly all other features of the mountains are, to atmospheric and stream erosion of the uplifted mass which constitutes the mountains, but have been formed by a dislocation of the earth's crust, or rather a series of such dislocations, in time past, with a differential movement of the parts on either side of the plane of rupture. In general this line follows a system of long narrow valleys, or where it passes through wide valleys it lies close to the base of the confining hills, and these have a very straight trend; in some places, however, it passes over mountain ridges, usually at the divide separating the ends of two valleys; it even in some cases goes over a spur or shoulder of a mountain. Along this line are very commonly found abrupt changes in the normal slope of the valley-sides giving rise to what are technically known as scarps. These scarps have the appearance of low precipitous walls which have been usually softened and rounded somewhat by the action of the weather. Small basins or ponds, many having no outlet, and some containing saline water, are of fairly frequent occurrence and they usually lie at the base of the small scarps. Trough-like depressions also occur bounded on both sides by scarps. These troughs and basins can only be explained as due to an actual subsidence of the ground, or to an uplift of the ground on one side or the other, or on both sides. The scarps similarly can only be ascribed to a rupture of the earth with a relative vertical displacement along the rupture plane. Frequently small knolls or sharp little ridges are found to characterize this line and these are bounded on one side by a softened scarp and separated from the normal slope of the valley-side by a line of depression. In many cases these features have been so modified and toned down by atmospheric attack that only the expert eye can recognize their abnormal character; but where their line traverses the more desert parts of the Coast Range, as for example in the Carissa plains, they are well known to the people of the country and the aggregate of the features is commonly referred to as the "earthquake crack."

This line begins on the north at the mouth of Alder creek near Point Arena and extends southeasterly nearly parallel with the coast line to a point about two miles below Fort Ross, a distance of 43 miles. Here it passes outside of the shore line and is again met with at the point where Bodega Head joins the mainland. Thence it appears to continue southward through Tomales bay and Bolinas lagoon. Beyond Bolinas lagoon it passes outside of the Golden Gate and enters the shore again at Mussel Rock, eight miles south of the Cliff House. From this point it is traceable continuously along the valley line occupied by San Andreas and Crystal Springs lakes, past Woodside and Portola, over a saddle back of Black mountain, thence along Stevens Creek canyon, passing to the southwest of Table mountain and Congress Springs to the vicinity of Wrights, on the narrow-gauge railway between San Jose and Santa Cruz. From Wrights it continues on in the same course through the Santa Cruz mountains to the point where the Southern Pacific railway crosses the Pajaro river near Chittenden. From the crossing of the Pajaro the line extends up the valley of the San Benito river, across the eastern portion of Monterey county, and thence follows the northeastern side of the valley of the San Juan river and the Carissa plains to the vicinity of Mt. Pinos, in Ventura county. The line thus traced from Point Arena to Mt. Pinos has a length of 375 miles, is remarkably straight, and cuts obliquely across the entire breadth of the Coast Ranges. To the south of Mt. Pinos the line either bends to the eastward following the general curvature of the ranges or is paralleled by a similar line offset from it en echelon; for similar features are reported at the Tejon pass and traceable thence though less continuously across the Mojave desert to Cajon pass and beyond this to San Jacinto and the southeast border of the Colorado desert. The probability is that there are two such lines, and that the main line traced from Pt. Arena to Mt. Pinos is continued with the same general straight trend past San Fernando and along the base of the remarkably even fault-scarp at the foot of which lies Lake Elsinore. But, leaving the southern extension of the line out of consideration as somewhat debatable, we have a very remarkable physiographic line extending from Pt. Arena to Mt. Pinos which affords every evidence of having been in past time a rift, or line of dislocation, of the earth's crust and of recurrent differential movement along the plane of rupture. The movements which have taken place along this line extend far back into the Quaternary period, as indicated by the major, well-degraded fault-scarps and their associated valleys; but they have also occurred in quite recent times, as is indicated by the minor and still undegraded scarps. Probably every movement on this line produced an earthquake, the severity of which was proportionate to the amount of movement.

The cause of these movements in general terms is that stresses are generated in the earth's crust which accumulate till they exceed the strength of the rocks composing the crust and they find a relief in a sudden rupture. This establishes the plane of dislocation in the first instance, and in future movements the stresses have only to accumulate to the point of overcoming the friction on that plane and any cementation that may have effected in the intervals between movements.

The earthquake of April 18, 1906, was due to one of these movements. The extent of the rift upon which the movement of that date took place is at the time of writing not fully known. It is, however, known from direct field observations that it extends certainly from the mouth of Alder creek near Pt. Arena to the vicinity of San Juan in San Benito county, a distance of about 185 miles. The destruction at Petrolia and Ferndale in Humboldt county indicates that the movement on the rift extended at least as far as Cape Mendocino, though whether the line or rift lies inland or off shore in that region is still a matter of inquiry. Adding the inferred extension of the movement to its observed extent gives us a total length of about three hundred miles. The general trend of this line is about N 35° W, but in Sonoma and Mendocino counties it appears to have a slight concavity to the northeast, and if this curvature be maintained in its path beneath the waters of the Pacific it would pass very close to and possibly inside of capes Gordo and Mendocino. Along the 185 miles of this rift where movement has actually been observed the displacement has been chiefly horizontal on a nearly vertical plane, and the country to the southwest of the rift has moved northwesterly relatively to the country on the northeast of the rift. By this it is not intended to imply that the northeast side was passive and the southwest side active in the movement. Most probably the two sides moved in opposite directions. The evidence of the rupture and of the differential movement along the line of rift is very clear and unequivocal. The surface soil presents a continuous furrow generally several feet wide with

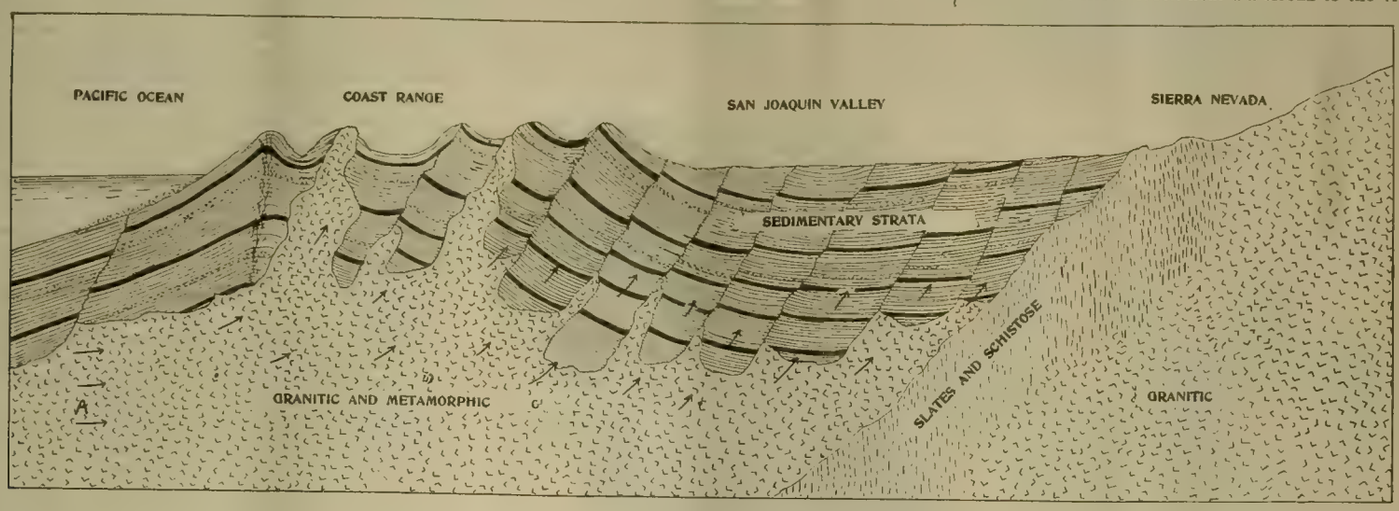


FIG. 1.

FIG. 2.

transverse cracks which show very plainly the effort of tortion within the zone of the movement. All fences, roads, stream-courses, pipe-lines, dams, conduits, and property-lines which cross the rift are dislocated. The amount of dislocation varies. In several instances observed it does not exceed six feet. A more common measurement is eight to ten feet. In some cases as much as 15 or 16 ft. of horizontal displacement has been observed, while in one case a roadway was found to have been differentially moved 20 ft. Probably the mean value for the amount of horizontal displacement along the rift line is about ten feet and the variations from this are due to local causes such as drag of the mantle of soil upon the rocks, or the excessive movement of soft incoherent deposits. Besides this general horizontal displacement of about 10 ft. there is observable in Sonoma and Mendocino counties a differential

FIG. 3.

vertical movement not exceeding four feet, so far as at present known, whereby the southwest side of the rift was raised relatively to the northeast side, so as to present a low scarp facing the northeast. This vertical movement diminishes to the southeast along the rift-line and in San Mateo county it is scarcely, if at all, observable. Still farther south there are suggestions that this movement may have been in the reverse direction, but this needs further field-study.

The great length of the rift upon which movement has occurred makes this earthquake unique. Such length implies great depth of rupture, and the study of the question of depth will, it is believed, contribute much to current geophysical conceptions.

The time of the beginning of the earthquake as recorded in the Observatory at Berkeley was 5 hr. 12 min. 6 sec. a. m., Pacific standard time. The end of the shock was 5 hr. 13 min. 11 sec. a. m., the duration being 1 min. 5 sec. Within an hour of the main shock twelve minor shocks were observed by S. Albrecht of the Observatory and their time accurately noted. Before 6 hr. 52 min. p. m. of the same day thirty-one shocks were noted in addition to the main disturbance. These minor shocks continued for many days after April 18, and in this respect the earthquake accords in behavior with other notable earthquakes in the past. The minor shocks which succeeded the main one are interpreted generally as due to subordinate adjustments of the earth's crust in the tendency to reach equilibrium after the chief movement.

The collection of time records necessarily proceeds slowly. The purpose of the co-seismal curves based upon these records is in general two-fold. In ordinary earthquakes it is one of the means of locating the seat of the disturbance when there is no surface manifestation of the rupture in the earth's crust. In the present instance, however, the rupture has declared itself in an unmistakable rift observable at the surface, and co-seismals are therefore unnecessary for the determination of this important factor in the general problem, so far at least as regards the main disturbance. It is probable, however, that so radical a change in the equilibrium of the stresses of the earth's crust would induce secondary ruptures and consequently secondary earthquakes closely associated with the chief shock. The careful plotting of the time records may, therefore, be useful in revealing the location of these secondary disturbances, such for example as the one which affected southern California on the afternoon of April 18. The second purpose of securing time records is the determination of the velocity of propagation of the earth wave; and the data for this which are likely to be most serviceable are the records obtained at various quite distant seismographic stations.

The destructive effects of the earthquake are in the main distributed with reference to the line of rift. The exact limits of the area of destruction have not yet been mapped, but it is known to extend out about twenty-five or possibly thirty miles on either side of the rift. On the southwest side the greater part of this area to the north of the Golden Gate lies in the Pacific. This area extends from Eureka in Humboldt county to the southern extremity of Fresno county, a distance of about four hundred miles.

Beyond this area of destructive shock the earthquake was felt in its milder manifestations over a wide territory. Our reports to date show that it was felt in Oregon as far north as Coos bay and on the south as far as Los Angeles. To the east it was felt over the greater part of middle California and western Nevada, particularly along the eastern flank of the Sierra Nevada. It was felt at Lovelocks, and we have unconfirmed reports of its having been felt at Winnemucca. Far beyond the region within which it was apparent to the senses, however, the earth wave was propagated both through the earth and around its periphery; and some of the most valuable and most accurate records of the disturbance which we have are those which were registered at such distant seismographic stations as Washington, D. C.; Sitka, Alaska; Potsdam, Germany; and Tokio, Japan.

Within the area of destructive effects approximately 400 by 50 miles in extent the intensity varied greatly. There was a maximum immediately on the rift line. Water-pipes, conduits, and bridges crossing this line were rent asunder. Trees were uprooted and thrown to the ground in large numbers. Some trees were snapped off, leaving their stumps standing, and others were split from the roots up. Buildings and other structures were in general violently thrown and otherwise wrecked, though some escaped with but slight damage. Fissures opened in the earth and closed again, and in one case reported a cow was engulfed. A second line of maximum destruction lies along the floor of the valley system of which the bay of San Francisco is the most notable feature, and particularly in the Santa Rosa and Santa Clara valleys. Santa Rosa, situated twenty miles from the rift, was the most severely shaken town in the State and suffered the greatest disaster relatively to its population and extent. Healdsburg suffered to a nearly similar degree. San Jose, situated thirteen miles, and Agnews, about twelve miles from the rift, are next in order of severity. Stanford University, seven miles from the rift, is probably to be placed in the same category. All of these places are situated on the valley floor and are underlain to a considerable depth by loose or but slightly coherent geological formations, and their position strongly suggests that the earth waves as propagated by such formations are much more destructive than the waves which are propagated by the firmer and highly elastic rocks of the adjoining hill lands. This suggestion is supported by a consideration of the destructive effects exhibited by towns and single buildings along the same valley line which are situated wholly or partly on rock. Petaluma and San Rafael, though nearer the rift than Santa Rosa, suffered notably less, and they are for the most part on, or close to, the rocky surface. The portions of Berkeley and Oakland which are situated on the alluvial slope suffered more than the foothills, where the buildings are founded on rock. The same suggestion is further supported from a consideration of the zone of maximum destructive effect on the southwest side of the rift. This zone lies in the Salinas valley. The intensity of destructive action at Salinas was about the same as at San Jose, and the town is situated on the flood plain deposits of the Salinas river. Along the banks of the Salinas river and extending from Salinas to the vicinity of Gonzales, so far as our reports at present show, the bottom lands were more severely ruptured, fissured and otherwise deformed than in any other portion of the State. The Spreckels sugar mill,

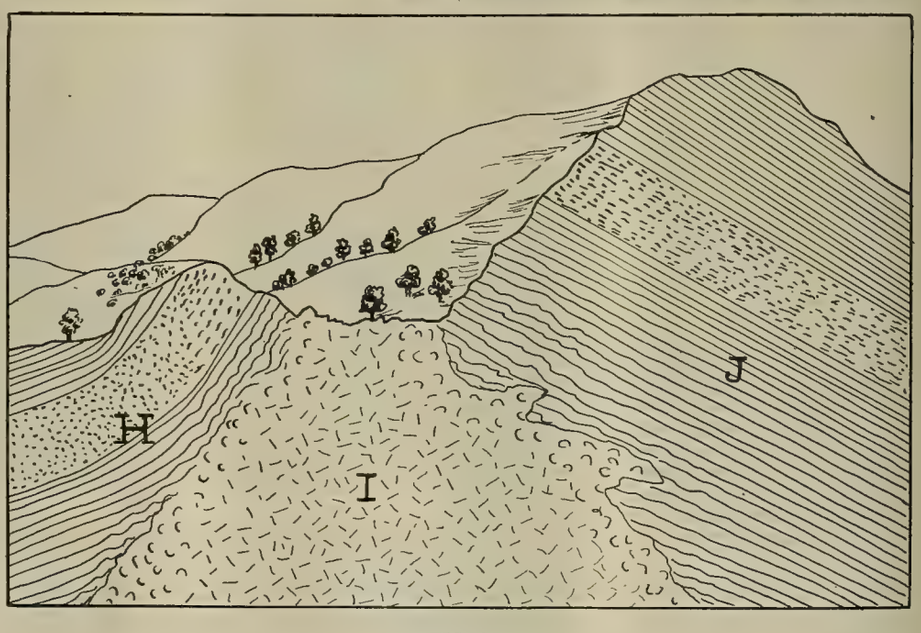

FIG. 4.

situated on the banks of the river, suffered more severely probably than any other steel structure in the State. Santa Cruz, on the other hand, which is on the same side of the rift, and at the same distance from it, but which is built on rock for the most part, suffered much less damage. In the northern counties along the coast the most severe effects were felt at Ferndale, on the south margin of the flood plain of the Eel river, and at Petrolia, on the bottom land of the Mattole. Ft. Bragg was severely shaken with very destructive effects, but our reports do not yet indicate the character of the ground upon which it is situated.

In the facts which have been cited we seem to have warrant for a generalization as to the excessively destructive effect of the earth wave as transmitted by the

little coherent formations of the valley bottoms. But it must be borne in mind that by far the greater number of structures subject to destructive shock are situated in the valley lands, and that there has not yet been time for a detailed comparison of the effects in the valleys with those in the hills, where the buildings are founded on firm rock, except in a few notable instances.

The most instructive of these instances is the city of San Francisco, and the facts observed there are entirely in harmony with the generalization above outlined. In the city of San Francisco we may recognize for preliminary purposes four types of ground: (1) The rocky hill slopes; (2) the valleys between the spurs of the hills which have been filled in slowly by natural processes; (3) the sand dunes; (4) the artificially filled land on the fringe of the city. Throughout the city we have a graded scale of intensity of destructive effects which corresponds closely to the classification of the ground. The most violent destruction of buildings, as everybody knows, was on the made ground. This ground seems to have behaved during the earthquake very much in the same way as jelly in a bowl, or as a semi-liquid material in a tank. The earth waves which pass through the highly elastic rock swiftly with a small amplitude seem in this material to have been transformed into slow undulations of great amplitude which were excessively destructive. The filled-in material and the swampy foundation upon which it rests behaved, in other words, as a mass superimposed upon the earth's surface, rather than as a part of the elastic crust itself. In a less degree the same thing is true of the sand dune areas, where the ground was frequently deformed and fissured. In still less degree the naturally filled valleys between the hill spurs were susceptible to this kind of movement, and the destruction of buildings was correspondingly less, but still severe, depending very largely on the character of the buildings, the integrity of their construction, etc. In portions of these valleys, however, the original surface of the ground has been modified by grading and filling, and on the filled areas the destruction was more thorough than elsewhere in the same valley tracts. On the rocky slopes and ridge tops, where, for the most part, the vibration communicated to buildings was that of the elastic underlying rocks, the destruction was at a minimum. On some of the hills chimneys fell very generally and walls were cracked; on others even the chimneys withstood the shock.

While this correlation of intensity of destructive effect appears to hold as a generalization, there are well known exceptions, which find their explanation in the strength of the structures. Modern class A steel structures with deep foundations appear to have been relatively passive, while the made ground in their immediate vicinity was profoundly disturbed. Thoroughly bonded and well cemented brick structures, on similarly deep and solid foundations, seem to have been equally competent to withstand the shock, except for occasional pier-like walls not well tied to the rest of the building. The weak points in wooden frame structures were in general the faulty underpinning and lack of bracing, and chimneys entirely unadapted to resist such shocks. With these faults corrected, frame buildings of honest construction would suffer little damage beyond cracking of plaster in such a shock as that of April 18, save on the made ground, where deep foundations and large mass appear to be essential for the necessary degree of passivity.

Pipe lines and bridges crossing the rift line present a peculiar, if not quite unique, engineering problem which will doubtless be solved in the near future. Pipe lines on low swampy ground or in made ground are in much greater danger of destruction from earthquake shocks than those on high ground underlaid by rock, except in the immediate vicinity of the rift, where nothing could be constructed which would withstand the violence of the earth movement.

One of the lessons of the earthquake which seems peculiarly impressive is the necessity for studying carefully the site of proposed costly public buildings where large numbers of people are likely to be congregated. In so far as possible, such sites should be selected on slopes upon which sound rock foundation can be reached. It is probably in large measure due to the fact of their having such a rock foundation that the buildings of the State University, at Berkeley, escaped practically uninjured. The construction of such buildings as our public schools demands the most earnest attention of the people and of the authorities charged with their construction. A great many of our schools proved to be of flimsy construction and ill adapted to meet the emergency of an earthquake shock of even less severity than that of April 18.

The Commission in presenting this brief report has had in mind the demand on the part of the people of the State and of the world at large for reliable information as to the essential facts of the earthquake. It has, therefore, not presumed to engage in any discussion of the more abstruse geological questions which the event naturally raises.

The Earthquake Explained.

Written for the MINING AND SCIENTIFIC PRESS by A. S. COOPER.

The coast ranges of California consist of a number of broken anticlines, fissured by faults and step-faults, nearly all of which run in a northwest and southeast direction roughly parallel with each other and with the valleys. Both sides of the fault are elevated but the northeast side is usually raised from one foot to several hundred feet higher than the southwest side.

The dotted and white line on the accompanying relief map shows the location of the master fault of the coast ranges. This fault extends from opposite Fort Bragg, in Mendocino county, to the Gulf of California, a distance of 700 miles. A wagon road follows 400 miles of its length. The movements of the earth which produced the earthquake of April 18, 1906, occurred almost simultaneously in this fault throughout its entire extent; consequently, there was no center of disturbance or seismic focus. The shock was of greater violence near Fort Bragg and San Juan, in San Benito county, than further south. Cracks and fissures can be seen from Tomales bay to San Juan. Two hundred miles of this fault broke into fissures of profound depth in about one minute, as is shown by the duration of the earthquake shock. The land on the northeast side of the cracks and fissures was elevated several feet higher than was the land on the southwest side. The fault marked by a white line on the relief map east of the master fault was also affected simultaneously, fissures opening for a long distance. All of the cities and towns lying within fifteen miles of this fault-line between Fort Bragg and Salinas City were badly damaged.

Fig. 1 is an ideal section from the Sierra Nevada through the San Joaquin valley and the coast ranges to the Pacific ocean in a northeast and southwest direction. As will be seen by reference to this section, all of the anticlines forming the coast ranges are faulted and fissured. The core of some of these anticlines is granitic while others have a core of metamorphic rock. The floor of the valley is also faulted, the fault being hidden by the debris deposited in the valley. These faults and fissures are formed by a mighty pressure coming from the southwest, caused by shrinkage of the earth by secular cooling. The direction of this force is represented by the arrows. This force is deflected upward by the immobility of the base of the Sierra Nevada. The upward deflection of this force is shown by the curved arrows. That this pressure exists is shown by the fissility of the slates and the foliation of the schistose rocks at the foot of the Sierra Nevada. The slates split in a northwest and southeast direction and the foliation of the schistose rocks is also in the same direction. The splitting of the slates and the foliation of the schistose rocks are at right angles to those lines of pressure, such cleavages occurring normally at right angles to the pressure.

Fig. 2, 3, and 4 represent the usual structure of the faulted and fissured anticlines of the coast ranges of California. Fig. 2 is an anticlinal structure which is bent so acutely that its apex is greatly fissured. Fig. 3 is an anticlinal structure faulted and fissured at F; both sides of the fault are elevated, but the side G has been raised from a few feet to several hundred feet higher than the side E. Fig 4 is an anticline having a metamorphic core I. Both sides of the core are elevated, but the side J is generally elevated many hundred feet higher than the side H. There is a faulting at K, between the metamorphic rock I and the sedimentary strata H. The sedimentary strata next to the metamorphic rock are abruptly bent upward by the ascent of the metamorphic rock. The side J is elevated, but usually there is no faulting between the sedimentary rock J and the metamorphic rock. Gases and mineral waters ascend through the fissures and cracks in these anticlines.

The elevation of the strata has progressed several

feet at a time. In the last fifty years in San Benito county the eastern side of the master fault was raised 14 ft., then two and one-half feet, then one foot and then two feet, higher than the western side.

When the lateral pressure described above has increased sufficiently to overcome the weight of the overlying rocks and the friction, the rocks on the side of the fault away from the ocean are suddenly lifted, producing a jar or earthquake. There being a greater pressure when the first movement of the earth occurs, the first shock is always the most violent. This is followed by minor shocks as the earth adjusts itself. A number of years will generally elapse before the lateral pressure increases sufficiently to produce another movement of a similar kind.

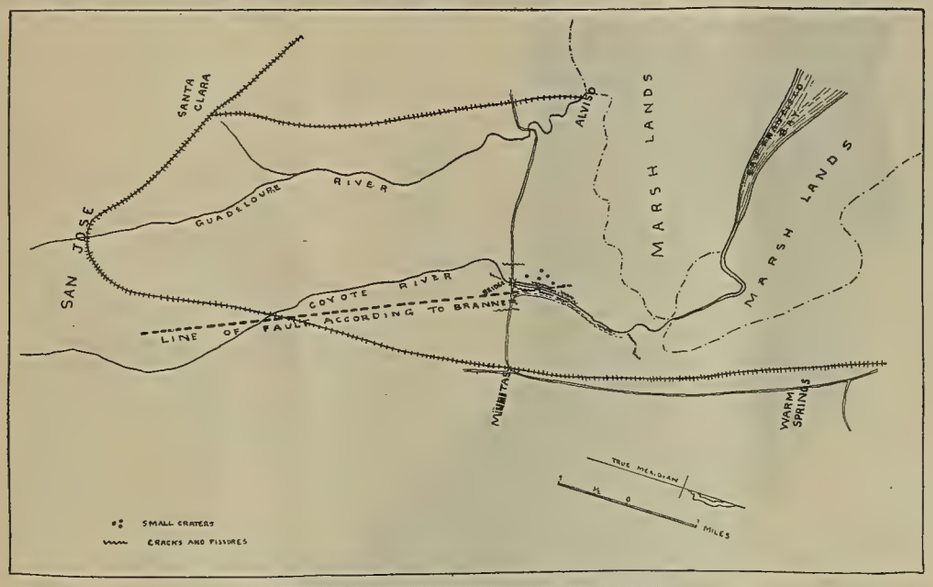
Mining in Honduras.—Consul Felix S. S. Johnson writes from Puerto Cortes, Honduras, to advise Americans not to invest money in mines in Honduras until the Government of that Republic makes roads so that machinery can be easily transported to the mines. He says: "Thus far the mining ventures of American companies in this consular district have mostly been failures. Machinery costing thousands of dollars, owing to poor roads or no roads at all, has in many cases never reached its destination and can today be seen on some trail or bank of a stream, a mass of ruins and rust. The country has no roads and it is a poor policy for persons to think of investing money in mining enterprises in this country until proper means for the conveyance to the interior is provided by the Government. I know of one or two mines in the interior, managed and owned by American companies, which are doing well. These companies have built their own roads to the Pacific coast and employ automobiles in carrying goods from and to the mines."

Remarkable Record of Coal and Ore Roads.—The results of operations in 1905 on the Pittsburg & Lake Erie and the Bessemer & Lake Erie roads are referred to by the 'Railroad Gazette' as little short of marvelous. It says: "When two railroads are able to show average revenue train-load figures, one of 937, the other of 1,076 tons, it is remarkable enough; but when we learn that the average tonnage southbound on one of them is 1,406 tons per train, there is a chance to realize the immense economies of modern methods of handling heavy tonnage. The Bessemer & Lake Erie, which shows this exceptional figure, is largely an ore-carrying road, ore furnishing nearly 6,000,000 of the 9,500,000 total tonnage. As part of the machinery developed by the United States Steel Corporation for transferring Lake Superior iron ores to the Pennsylvania mills, the road shares in the tremendous economics which have been brought about by modern methods of handling and transportation. On the Pittsburg & Lake Erie, on the other hand, coal and coke furnish over 14,000,000 of the nearly 25,000,000 tons, ore amounting to not quite 3,500,000 tons. A large tonnage of manufactured iron and steel products, in addition, helps to make the road nearly twice as heavy an earner on a mileage basis as the Philadelphia & Reading, which has the next largest gross earnings per mile of any American railroad. The fact that the Vanderbilt road is operated at 43.4% of gross for expenses, and the Steel Corporation's line at 48.99% goes to show how profitable railroad operation can be when sufficient traffic is available."

Effects of the Earthquake.

Written for the MINING AND SCIENTIFIC PRESS by D'ARBY WEATHERBE.

For some time previous to the earthquake, John C. Branner, professor of geology in Stanford University, had been examining the topographic and geologic conditions throughout the Santa Clara valley and the adjacent mountains on either side. He came to the conclusion that there existed a zone of fracture or a line of faulting which intersects the Coyote river near the bridge on the road from Milpitas to Alviso. This fault is said to have a course approximately northwest and southeast and some rather remarkable demonstrations of the earthquake have occurred along the levee paths following the Coyote river north from the bridge mentioned. It should be stated in passing that the alluvial deposits of the Santa Clara valley are immensely deep—how deep is not known—although boreholes for artesian wells have been sunk over 1,000 ft. in sand and gravel. At the locality mentioned large fissures, as much as eight feet wide and of nearly equal depth, have been opened and as partial filling ensued immediately, they must have been of much greater depth when first formed. In some places the road has been completely precipitated into the creek and at a point about half a mile below the bridge both the banks and the bed of the stream, including a heavy growth of willows, have been cut by a series of parallel cracks and the trees and banks thrown into the stream, thus forming a partial dam.



SKETCH MAP SHOWING LINE OF FAULT.

All of these cracks are roughly parallel with the stream and approximately with the supposed course of the fracture zone in the rock far below the surface. Simultaneously with the above phenomena, dozens of small geysers or spouting craters were formed along the creek and in the adjacent fields. The mouths of these varied in diameter from three inches to about 15 in., though the actual orifices probably do not exceed four or five inches in diameter. Mud and water were spouted to a height of over twenty feet, and continued to flow for several days. On some of the miniature craters incrustations of salt were deposited. The bridge above-mentioned was shifted on its concrete supports, the two ends moving in opposite directions, and throughout the same locality rows of trees in the orchards are said to have been twisted and staggered out of shape. Above the valley to the east, in the solid rock of the mountains, practically no damage was sustained.

D. Rowan, who accompanied me on the above examinations, spent several days on the Marin side of the Golden Gate, along the Pacific coast, and reports the following effect of the earthquake in that locality: The road crossing the sand-spit at the mouth of Bolinas bay is fissured and in places disturbed, and the high cliffs—about 150 ft.—at the end of the peninsula have crumbled and fallen down, carrying small trees with them. At the village of Bolinas, the soil has slipped down easterly toward the lagoon and on the east side of the road, which runs north and south, the buildings are entirely demolished, while those further up the hill on the west side are not so badly affected. From Bolinas to Olema the road is disturbed all the way. About half a mile west of Olema at Skinner's dairy a well-defined fissure passes north and south under the barn, which is completely wrecked; the garden, lying between the two buildings has slipped down the hill toward the lagoon in a northeast direction, following the slope of the land. It is said that higher up on the hills to the southwest of Olema the effect on the ground was worse and at a point about two miles in this direction an opening occurred in a yard where a cow was being milked, which swallowed up the animal so that its hind legs only were left out of the ground. From Skinner's the road runs north toward Inverness and for a distance of two miles it is so badly broken as to make vehicular traffic impracticable. The road from Inverness to Reyes Point station, running easterly and westerly and between one-half and three-quarters of a mile long, has broken about the center, the western portion being carried north 16 ft.; a block 30 to 40 ft. long has dropped down four feet. At Reyes Point station freight-cars, standing on the siding, were overturned to the west, following the slope of the ground. At Inverness, on the peninsula across Tomales Bay, the buildings along the low ground at the water-front were entirely demolished; in many cases they were thrown into the water and the wharves, being apparently on short piles, were badly wrecked. Higher up on the hill, the motion was not felt to such an extent. Along the coast, the railway was greatly disturbed, invariably sinking in the low swampy land except where built on piling. At Tomales, about eight miles inland, the line for over 1,000 ft. was carried down a gentle slope to the east for a distance of 50 ft. All these disturbances are exactly along the faulted line, now well defined, though the movement and action in each of the cases above noted has been entirely local and following the configuration of the ground. Little evidence, therefore, can be deduced pointing to a definite regional movement in any certain direction. Buildings on ground resting on long piles seem undisturbed and the worst effects are noted on or toward swampy ground.

Chromite. The only important ore forming the raw material for the manufacture of chrome and its ferro-alloys is chromite, FeO Cr_2O_3, containing 68% chromic oxide. Often, the ferrous oxide is replaced by magnesia and the chromic oxide and alumina, and it generally contains variable quantities of silica. The total yearly output from all sources is 70,000 tons, the greater portion of which is employed for the manufacture of chromates, bichromates and refractory furnace linings. Ores for the production of ferro-chrome should be as pure as possible and free from silica, as the latter element has a tendency to enter into the alloy instead of going into the slag, when smelted in the electric furnace. A suitable ore should contain at least 50% of chromic oxide.

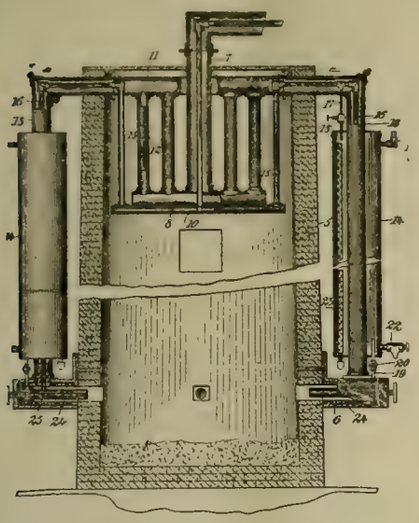
The Yukon.—From being a "graveyard of navigators" the upper Yukon river has become practically as safe as a canal. During the open season steamers, barges, scows, canoes in great numbers ply its waters, and accidents of any description are extremely rare. The Yukon forms a convenient highway through the central portions of this great Northwest. Its traffic is divided between the White Pass and Yukon route (railroad and steamers) from Skagway to Dawson, and the American route from Seattle to Dawson via St. Michael. Generally speaking, Yukon Territory and the Forty Mile district in Alaska are served by the Canadian route, while the American route supplies the wants of the lower river points, including the Tanana, Koyukuk, and Rampart mining district. Fairbanks alone, during the present winter, required as large stores of provisions as Dawson. In its solicitude for the welfare of Yukon Territory the Canadian government has annually voted grants, not only for the construction and maintenance of roads and trails—about $200,000 for the fiscal year ending June 30, 1905, or $1,386,400 altogether from 1899 to January 31, 1906—but also for the improvement of the Yukon river and its tributaries. The program for the current year provides for an expenditure of $15,000, to be distributed as follows: $8,000 for rock blasting at Hell's Gate, $1,500 for the Fortymile river, $3,000 for the upper Yukon reaches, including Thirtymile river, and $4,000 not yet placed. Since the opening up of this country a few years ago Canada has appropriated about $175,000 for Yukon river improvements. On the American side of the line, in Alaska, improvements have not even started. The Yukon flats are still there to endanger and retard American shipping, and so are the obstructions at the mouth of the river, which were fully described and explained to the senatorial subcommittee who personally, in 1903, investigated conditions in Alaska. It should be thoroughly understood, in this relation, that transportation is the chief problem in this wonderful northland. It is the paramount question in the development of Alaska.

Mining and Metallurgical Patents.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

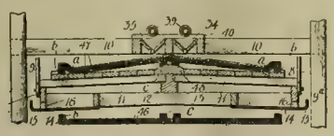
CUPOLA, No. 820,210. J. H. Koons, Delphos, Ohio.

The combination with a cupola and twyer-boxes communicating therewith, of a heater comprising low-pressure pipes arranged in the cupola and communicating with the twyer-boxes, high-pressure air-pipes arranged in the heater and communicating with the twyer-boxes, oil-tanks communicating with the twyer-boxes, and means for heating the oil therein.



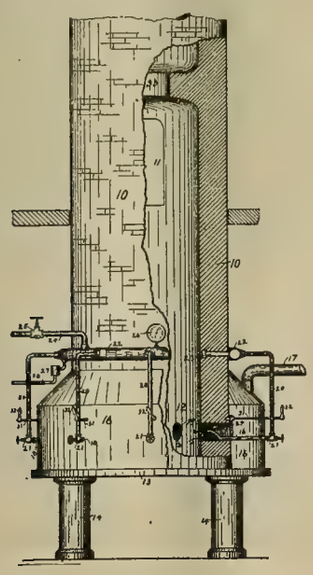
ORE-SLIMER, No. 820,234. I. F. Monell, Boulder, Colo.

In a machine of the character described, an endless apron or belt having its upper stretch inclined from its longitudinal center outwardly, strips secured underneath the edges of said apron to form pockets along the upper edges of said apron, strips secured underneath the longitudinal center of said apron, in combination with oppositely-tapered rollers over which said belt travels, an oppositely-inclined flooring having an elevated crown-strip, over which the center strips of the belt pass, and means for discharging pulp upon the opposite sides of the longitudinal center of the belt.



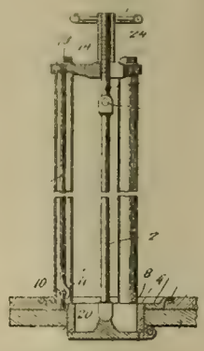
CUPOLA, No. 820,167. Winfield S. Anderson, Cincinnati, Ohio.

In a cupola or similar device fitted for using liquid fuel, the combination of a working chamber, a fuel-heating pipe arranged around the wall which surrounds this working chamber and provided with communicating, inwardly-projecting heating-spurs which are embedded into this wall so as to derive heat therefrom, means to supply a hydrocarbon to this pipe and its spurs so as to be preheated therein, burner-nozzles arranged to discharge into the working chamber and feed-pipes connecting them with the fuel-heating pipe.



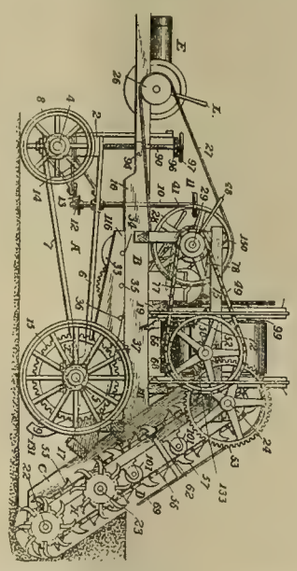
CYANIDE-TANK GATE, No. 820,116. John Ike, Deadwood, S. D.

In a device of the class described, a pair of spaced bearing-heads, one of said heads having a slot, and the other being provided with a tubular extension constituting a seat, tie elements operatively engaged with and for connecting said heads, a gate pivoted to the tubular extension and adapted to close on the seat, a stem operatively connected with the gate and designed for entrance into said slot, and a hand-wheel having a tubular hub threaded onto the stem and designed for engagement with the adjacent bearing-head.



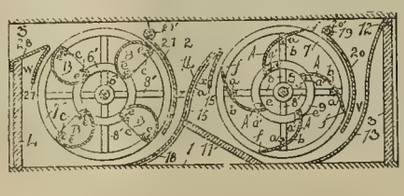
EXCAVATING AND DITCHING MACHINE, No. 820,152. James K. Sweeny, Pueblo, Colo.

The combination in an excavating apparatus, of a frame, wheels supporting the same, and a second frame extending over the first and supporting the working parts and pivoted on the front axle of the running-gear frame to permit the forward end of the supporting-frame to be raised and lowered, the pivotal point being about midway of the weight of the frame and apparatus.



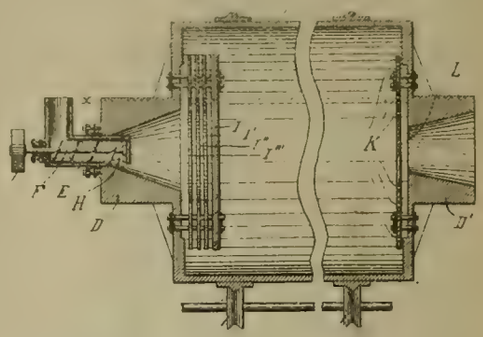
AMALGAMATOR, No. 820,189. Charles E. Gard, Ord and John W. Lynn, Omaha, Neb.

A housing provided with an intake-opening and an exit-opening, a curved end plate secured near the intake-opening of said housing, a curved guard-plate placed adjacent to said end plate to form a channel, a shaft passing transversely through said housing, a plurality of perforated agitating-knives secured to said shaft and rotating adjacent to the end of said channel, a curved partition provided with a downwardly-extending apron, a second curved guard-plate positioned adjacent said partition to form a second channel, a second shaft passing through said housing, a plurality of troughs secured to said shaft, said troughs having opposite edges recurved, an inclined tail-plate secured adjacent the exit-opening within said housing provided with a downwardly-extending apron, and means to operate said shafts.



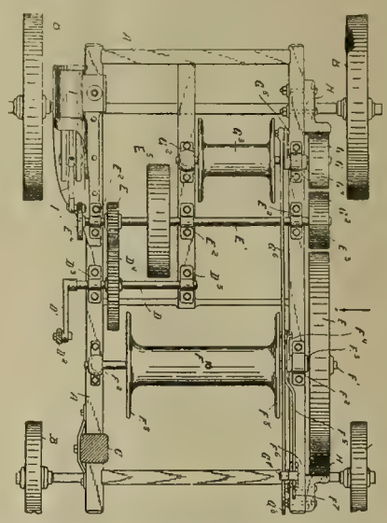
PEBBLE-MILL, No. 820,559. George S. Emerick, Philadelphia, Pa.

The combination in a ball-mill of a feed mechanism therefor, consisting of a non-perforated plate or disk and a ring-shaped plate or disk spaced between the said non-perforated plate and the feed end of the mill-cylinder, said non-perforated plate and ring-shaped plate being parallel each to each.



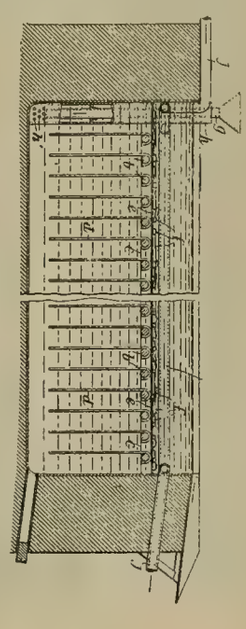
WELL-DRILLING MACHINE, No. 820,936. Claude M. McAfee, Waco, Tex.

In a well-drilling machine, the combination with an engine-shaft, of a walking-beam shaft directly connected to the engine-shaft, a bull-wheel shaft directly connected to the engine-shaft, and a sand-reel shaft directly connected to the engine-shaft.



RECOVERY OF COPPER FROM SOLUTIONS CONTAINING IT, No. 820,555. Benvenuto Comba, Turin, Italy.

The method of recovering copper from solutions containing it, which consists in placing the solution in a suitable vessel, immersing a cathode therein, superimposing a liquid of less specific gravity upon the surface of the copper solution, and supporting an anode in said supernatant liquid, in direct contact with the cathode, whereby an electric current is generated and pure copper is deposited upon the cathode.



MINING SUMMARY

ARIZONA.

COCHISE COUNTY.

E. E. Cochreham during May did 100 ft. of work in 21 days, in an incline, on the property of the Paradise Development Co. The shaft is now down to a depth of 225 ft. When 250 ft. shall have been reached, S. S. Badger, the owner, intends to cross-cut the formation. Both water and ore were struck in the incline at 225 ft. where there are two feet of sulphide copper ore. It has been decided to sink 350 ft. before drifting. A steam-hoist is planned, and should water become troublesome, a steam-pump will be installed.

GRAHAM COUNTY.

(Special Correspondence).—John Molder, owner of the Buzzard Shadow claims in Coronado Mountain district, shipped a ton of ore from the claims to the El Paso smelter last week, which will run $100 to $125 per ton. He is expecting to make another shipment in about ten days.——It is reported in this district that the Lampazos mine and smelter have been purchased by the Phelps Dodge Co., through J. S. Douglas, of the Montezuma Copper Co. at Nacozari. The mine and smelter are the property of M. A. Lopez of Lampazos. He has been operating for the last four years, and is the largest producer of the metal south of Nacozari. ——E. U. Beauchamp, manager of the Gold Belt Development & Reduction Co., passed through Morenci on his way to Clifton recently. He has had fourteen men working on his property for the past three years. The new hoist has arrived in Clifton, and will be taken to the mine over the wagon road just completed. The lead claims of the company are being put in condition for shipment of ore to the smelter at El Paso. ——The annual meeting of the Home Copper Co. directors was held in Morenci on May 28, and new officers were elected. The shaft now being sunk will be continued and the force increased. The new officers are H. J. Degenar, president; W. A. Leonard, vice president; W. P. Gee, secretary and treasurer; John Burns, T. F. McClellan, James Bartlett, Paul Becker, H. J. Degenar, W. A. Leonard and N. L. Jenkins, directors. N. L. Jenkins, who has been in charge of the work for the past two years, has been retained as superintendent and general manager. The Home Copper Co. was organized several years ago, but no systematic work was done until within the last two years. A new wagon road connects the claims with Morenci.——The recent reports from the Ash Peak district in this county are of interest. The Ash Peak Mining Co. of Boston, owns property situated eleven miles north of Duncan in this county. It is under the management of A. Murphy, Jr. There is now 1,100 ft. of work done on the property. The assays of the ore taken from a 40-ft. shaft return 800 oz. silver, besides gold. The shaft will be continued to a connection with the tunnel, and a mill will be erected. The ore is 90% silica, and it is thought it can be cyanided.

The Allen gold mine, below Newtown, has been closed down for the summer. Some rich ore has been taken from this mine during the past few months, the first shipment of a carload netting $4,350. Another shipment was made last week.——On April 21, the millmen at the Detroit Copper Mining Co. concentrator signed a petition requesting the granting of an eight-hour day. The company offered the men the choice of continuing on the basis of twelve hours as in the past with the same rate, or reducing the day to eight hours with a cut of fifty cents per man per day. The men refused to accept either of these propositions and sent word to the superintendent that they would stay at work under the present scale until May 1. In consequence, on that date, the foreman of the concentrator received word to shut down the mill. The men received their pay and nearly all left camp within a few days. A large proportion of the men has been in the employ of this company for a number of years, and were reluctant to leave. The mill was closed down for ten days, the ten-hour repair men being the only force working. Last week a force sufficient for operation was recruited, but most of the men are new to the work and the service and output are unsatisfactory as yet.——On Friday, June 1, the millmen of the Arizona Copper Co. concentrator No. 5, followed the example of the Detroit Co. men, under the same conditions. This mill is still idle. It is expected that similar demands will be made at the mill of the Shannon Copper Co.——On May 1, the Arizona Copper Co. voluntarily made the concession to their force of carpenters, of Saturday afternoons and Sunday as overtime, with a rate of time and a half. Learning of this, the Detroit Copper Co. carpenters, engaged in the erection of a new mill, asked for the same scale, and it being refused, they struck, and as a consequence that part of the work is also at a standstill.——The Detroit Copper Co. is laying a new ten-inch pipe-line from the double hill tanks to connect with, and furnish water to the new concentrator. A new location was found which necessitated pumping, the new line being laid so that the water will flow entirely by gravity.

Morenci, June 9.

MOHAVE COUNTY.

It is reported that the heat has been so great in the Bill Williams Fork country the past month that numerous mines have been closed down for the summer.—— A mill of 100 tons' daily capacity is to be placed in the Cupel mine at Stockton hill, by W. H. Cushing.—The lessees of the Little Chief mine at Stockton hill are breaking eight inches of very rich silver-gold ore, which they are shipping. The mines of this camp are frequently rich in wire and ruby silver.—The Arizona-Minnesota Gold Mining Co., it is reported, will rebuild the O. K. mill, or build a mill at the mine, thus dispensing with the long haul between mine and mill. The Eldorado mine was in good ore at the time of the shutdown, caused by the destruction of the mill by fire.

CALIFORNIA.

AMADOR COUNTY.

(Special Correspondence.)—It is reported that the Keystone mine, one of the largest and oldest gold mines of the State, has been sold to the Bagdad-Chase Mining Co. of New York, for $1,000,000, of which $250,000 are said to have been paid. The Keystone mine is about 1,600 ft. deep, but the greater part of the development, consisting of upward of 10 miles of workings, is above the 900 level. The equipment consists of hoist and 60-stamp mill, motive power being furnished by electricity and compressed air. The Bagdad-Chase Co. is also operating the Soulsby mine at Soulsbyville, in Tuolumne county, under bond.

Sutter Creek, June 10.

BUTTE COUNTY.

It is reported that a gold strike has been made in the vicinity of Pentz, in a gravel mine on Dogtown ridge six miles north of Cherokee, by Hendrix brothers of Oroville, and G. M. Reaves of Magalia. The past two years they have been driving a tunnel, and finally encountered the channel with a pay-streak running $5 gold per cu. yd. The Blue Hog Ranch mine is believed to be an upper extension, and the strike will probably result in the Blue Hog resuming operations.

A new strike has been made by M. J. Cooney, at Oroville, not far from the Spring Valley mine at Cherokee. Mr. Cooney made two locations on the vein, which he found outcropping 30 ft. wide. Accompanying it on the hanging wall is another vein six feet wide. At the contact is a pay-streak of high-grade ore. The quartz all pans free gold. The vein has been traced for 1,000 ft. on the surface. A pick had never been stuck into it before Mr. Cooney located it.

COLUSA COUNTY.

The strike of quarrymen employed by the Colusa Sandstone Co. and the McGilvray Stone Co. at Sites has been settled and the men have returned to work. The terms on which the strike was settled have not been made public.

NEVADA COUNTY.

Pay gravel is reported struck at the Jenny Lind mine near Nevada City. The mine was first worked as a quartz mine, but failing to develop anything, a large gravel bank was prospected and proved encouraging. A great deal of work has been done, and now the channel has been opened. It is supposed to be the continuation of what is known as the Alta channel, which was worked years ago.——A 700-ft. tunnel has been run to connect with the shaft on Iron Mountain west of Grass Valley. The shaft is down 165 ft. It is believed a body of copper ore will be developed.

SAN BERNARDINO COUNTY.

A copper strike was recently made six miles west of Soda lake, by M. T. Amos, J. C. Amos and Charles Gray. The main vein is from one to ten feet wide, and assays run as high as $125 copper and gold, of which from 12 to 20% is copper. The locators have staked out 31 claims in two groups. Two tunnels of 1,000 ft. each have been run, which will give 600 and 1,000 ft. respectively, of backs. The mine was worked 30 years ago for silver, but was abandoned.—The Sunrise district is 20 miles south of Needles, the settlement being called Cluresville. The first strike was made in February, 1905, on the Blue Bird. Then the Dollar mine was struck by McClure and his partner. It was on the surface, but they shipped some of the ore to a smelter and none of it ran less than $100 per ton, and some of it ran $1,000. The property was bought by the Woods Investment Co. of Los Angeles, which owns 40 claims in the district.—Among the Eagle mountains, six miles north of the McClure mines, is the Big Four, now under bond to Mr. Graham, of Douglas, Arizona. The vein is 20 ft. wide and some of it is rich. The owners are sacking ore, which carries gold and copper. In the vicinity are also lead-silver deposits.

SHASTA COUNTY.

At the new smelter camp of Coram, four miles south of Kennett, 100 men are employed grading on the smelter site and on the Southern Pacific railway spur, and also on the six-mile wagon road to the Balaklala mine. An additional force of 200 men is expected any day to rush the work on the spur, which leads from the main track to the smelter, and which will be about a mile and a half long.

TEHAMA COUNTY.

The California & Massachusetts Copper Mines Co. has bought a number of claims on and near Tom's Head mountain. About 340 acres of mineral ground are covered by the transaction. The company will begin development work on three of the prospects, and a mining district will be organized to be known as the Red Bluff mining district.

TULARE COUNTY.

Robt. Johnston of Visalia, intends to open up another granite quarry on South Tule. He is now employing six men.

COLORADO.

BOULDER COUNTY.

A dozen lessees on the American Star mine, on Left-hand creek, are greatly chagrined because last week they served notice of the surrender of their lease, as it did not pay. L. R. Johnson, of Boulder, manager of the company, notified the company at Hartford, Conn., and received instructions to make other arrangements. Meanwhile the lessees sent down a carload of 30 tons, which ran high enough to give each lessee $10 per day for all the time he had put in for six weeks. They notified Johnson that they had probably made a mistake. He agreed with them, but declared it too late for renewal, and the company will develop the strike on its own account.

GILPIN COUNTY.

The O. K. property on German hill in the Gregory district, southeast of Central City, has been sold to A. H. Frost of San Diego, Cal., and J. R. Hastings of Chicago, Ill. The main shaft of the O. K. mine is down over 600 ft. and during the past year the property has been extensively developed by Anderson & Co., and a number of lessees have been at work. Shipments of concentrating and smelting ore have been made, large orebodies have been exposed, and the property is reported to be in shape for heavy and regular production. The new owners have arranged to have the main shaft repaired and the force is to be increased as soon as active operations are in full swing. C. H. Karns of Central City is superintendent.

GUNNISON COUNTY.

A $10,000 electric light and power plant is proposed by the Taylor Park Mining Co. for the Enterprise mine. The Enterprise mill is idle while repairs are being made.——Chas. Hubbard has been steadily taking out ore from the X-10-U-8. He is sacking the best and stacking all below $40. It is the intention to take this ore out via Cement creek. W. W. Roof is working the Black Warrior through the Hubbard tunnel. He has found some rich ore, and has made a raise to connect with the shaft on original workings of the Warrior. ——At the Forest Hill mine machinery is being brought down from the old workings to the new shaft.——At Pie Plant mén are working steadily, and the Doctor mine has ore ready to ship. The high price of silver and lead is putting life into the mines of Italian mountain.——Howard Marshall has worked for the Enterprise mine all winter, keeping open the Taylor trail. For the last two months the teams have started every morning at three o'clock to make the pass when snow was crusted and before slides began to run. A dozen slides have come down, but always after the teams were safely over with their ore wagons and supplies.

LAS ANIMAS COUNTY.

Manuel Martinez, a Mexican coal mine worker, has been arrested, charged with having set fire to the Engleville coal mine owned by the Colorado Fuel & Iron Co. Martinez was discharged from the mine three weeks ago and the next day the property began to burn. Hundreds of miners were imperiled, many of them being saved with difficulty. The fire is reported to be still burning fiercely. The loss is estimated at over $100,000.

SUMMIT COUNTY.

(Special Correspondence).—The Old Union has made

a rich strike in the bottom level where the breast of the main tunnel shows four feet of zinc ore of shipping grade. Beside this is a body of concentrating ore which is being milled. The 150-ton mill is running full time, producing high-grade lead and zinc concentrate. It is equipped with ten Wilfley tables.——The Wellington mine is making large and regular shipments of lead and zinc ore.——The Country Boy lessees have now the finest body of zinc ore in the district and are shipping black sulphides which run 50% zinc in car-load lots, just as taken from the vein. They are also piling up a large tonnage of low-grade ore to be treated at their own mill.——The Bullion King mine is shipping high-grade lead-zinc ore containing silver with some gold.——The Atlantic mine on North Star mountain is increasing its force and will resume shipment in the course of a week. The roads have been too bad of late for hauling and in consequence a large supply of ore is on hand awaiting shipment. The vein producing this ore is from 15 to 20 ft. wide. It averages three to five ounces gold per ton.——The Dunkin mine worked by lessees is in the shipping list and producing well.——The Jessie mine has its 40-stamp mill running, and the ore in the bins is high grade. A strike of $500 ore was recently made in this property. ——H. W. Spaulding has been appointed superintendent of the Mekka Placer Gold Mining Co., operating in French gulch. Hydraulicking is now in full swing and the ground of the old Oro Co. will soon be washed.——J. C. Putner, of Denver, is in charge of the renewed operations on the Wire Ranch mine on Farncomb hill. He has men opening up the orebodies, and mechanics are putting the mill in order.——The Sallie Barber mine on Nigger hill, has been working on a high-grade zinc vein for some months past and making large shipments. This vein has now opened up to nine feet of solid zinc-blende.——The Abundance Mining & Milling Co. started the diamond drill in operation in Yuba Dam Flats today; they being at a depth of 120 ft., at which point the churn-drill was stopped on account of the solid rock being encountered. In the operation of the churn-drill a body of over 40 ft. of low-grade ore was passed through. This would pay to handle with a big mill on the property.

Breckenridge, June 9.

TELLER COUNTY.

On the Isabella property, in Cripple Creek district, thirty sets of lessees are working, and their work, together with that of the company during the month of May, produced 60 cars of ore which was the average value of $30 per ton, making a total of $45,000. The company work is confined to development in both the Lee shaft on the Isabella and the main workings on the Empire State. Only one lease has so far been granted on this portion of the estate.

OURAY COUNTY.

The Ouray City Mining Co. has begun diamond-drilling operations in the southeast part of Ouray. Two shifts are being worked at present, and they are going down at the rate of 25 ft. per day. It is thought that if the formation is not too badly broken they will cut four contacts within 300 ft. of the surface.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence).—It is announced that a company is about to be formed for mining in the Coeur d'Alene, and that the company will be one of the biggest mining corporations in the West, with W. A. Clark of Montana, as chief stockholder, with Bracking and Ebbley of Wallace, George W. Winters, of Butte, and Joseph Pyle among the stockholders. The intent of the proposed corporation is to drive a tunnel, beginning on the claim known as the Phoenix No. 7, near Burke, and extend it until it taps the Hercules vein at a depth of 1,250 ft., 600 ft. below its present greatest depth, and to extend it to a total length of four miles, and cut the Tamarack and Chesapeake lode at a depth of 1,500 ft. below the 1,600-ft. level.—— A. Page of Wardner has paid $19,000 cash for D. McEachran's interest in four claims on Government gulch. Page and Dedlin own a majority of the stock of the United States Co., joining the Bunker Hill on the east, the Silver Creek group of three claims, the Black Hawk and Wyoming mines west of the Federal and Bunker Hill Co.s' holdings, and the Western group of 107 claims extending west from them almost to Pine creek. Mr. Page also closed a deal on a six months' bond for John Corrigan of Silver creek on claims three miles west of Wardner, adjoining the Western group.——The Coeur d'Alene Consolidated Mining Co. has been incorporated by Spokane and Coeur d'Alene people, and will develop a group of silver-lead claims near Osborn. ——Chas. Sweeney of Spokane, president of the Federal Mining & Smelting Co., reports a strike on the Tiger-Poorman of six feet of ore, of which a third is galena carrying 55 to 60% lead, and four feet of concentrating ore that runs 10% lead. This was found at the 2000-ft. level——The Federal Co. is putting in, at its Morning mine at Mullan, a plant to treat 325 tons of tailing daily. The Bunker Hill & Sullivan Co. has ordered a concentrating plant to treat its entire tailing dump.——The Hecla Co. has paid its 35th dividend of $20,000, making a total of $680,000 paid in dividends, of which $240,000 were paid last year.——W. A. Boyd of the Coeur d'Alene Concentrating Co. has returned from New York, where he contracted for $10,000 worth of machinery to be used on the company's property near Wallace.

Wallace, June 9.

NEVADA.

LINCOLN COUNTY.

(Special Correspondence).—The Quartette Co. has installed a new 100 h.p. gasoline engine, which is to furnish power for the electric light plant, compressor and electrical pump.——A shipment of ore made by Stoner to the Phoenix, Ariz., smelter, consisting of 2100 lb., netted $288 after freight and treatment charges were deducted. Steady shipments will be made.—— The Nevada-Searchlight has struck a good shoot of ore in the Grand Central claim and sinking to water level, which should be encountered at 200 ft., will be continued.——It is reported that the Southwestern Co.'s entire property is under option. This company has extensive holdings in El Dorado canyon and in the surrounding country. W. A. Clark is said to be the purchaser.——The Searchlight Bonanza Co. has put in a gasoline hoist and is making surface improvements.

Searchlight, June 8.

NYE COUNTY.

(Special Correspondence.)—The offices of the Vegas & Bullfrog railroad are now at Johnnie siding, 12 miles north of this place, and the auto road to that point is completed. The auto makes the trip over and return daily from here—formerly two days by stage from Ivanpah or Good Springs siding. Prospectors are coming and mine owners are taking out ore for shipment. ——At the Johnnie Consolidated they are sacking ore from the grass roots that assays $1,000 per ton. This is free-milling gold ore. Parties with wagons, and prospecting outfits well prepared for good serviceable work, as well as burro outfits, are becoming plentiful. This season the fruit crop at ranches in this part of the State will be immense. Our whole country in southwestern Nevada is coming to the front and only requires money for development, for the mines are here.

Johnnie, June 9.

On the third level of the Denver, at Rhyolite, an orebody 300 ft. long has been opened. The level has shown values from the beginning, but came into the rich ore at the junction with the winze. The vertical depth is 300 ft., which has been gained after driving 570 ft. The second winze from the third level, 200 ft. beyond the first, is down 35 ft., and continues to show good ore.

It is reported that a movement has been started to consolidate the Tonopah Mining Co., the Tonopah-Extension, Tonopah-Belmont, Montana-Tonopah, the Midway and the Jim Butler mines at Tonopah. The only producing mines of the camp not included in the consolidation being the West End, McNamara, and North Star.——A report is also being circulated to the effect that eight feet of ore assaying $75 per ton has been cut in the McNamara, on the 300-ft. level, at 100 ft. from the end line of the West End.

NEW MEXICO.

GRANT COUNTY.

The Burro Mountain mining district is 15 miles southwest of Silver City. Although it was discovered at an early date in the history of mining in New Mexico, it really is a new camp, and it is only recently that capital has become interested in the mines. It is a district of low-grade copper ore, and also produces turquoise. The Comanche Mining & Smelter Co. is interested in the camp, and expects to continue the narrow-gauge railroad, which is built from Pinos Altos to Silver City, down to the Burro comp.—The Comanche Co. and the Burro Mountain Copper Co. are the principal owners in the camp. The first-mentioned company has claims which are mainly in the body and adjoin the holdings of the Burro Mountain Copper Co. Developments have been carried on in this property through three shafts sunk on different veins running parallel. The ore is mainly low-grade carbonate.—The Burro Mountain Copper Co. has 600 acres of ground in which the quality of the ore and the size of the veins are about the same as in those of the Comanche Co. The Burro company works a large force of men. It has 5,000 ft. of work done on the property. The ore is treated in the company's concentrating mill, which has 250 tons daily capacity. The concentrate is freighted to Silver City for treatment at the smelter. The town of Leopold, of about 800 people, has grown up since the Burro Mountain Copper Co. began work. They have electric lights and are supplied with an abundance of fresh water from Deadman's canyon. Among other companies carrying on development in the district are the Copper Gulf Mining Co., the Tip Top Mining Co. and the Alessandro Copper Co.

OREGON.

JACKSON COUNTY.

C. W. Evans has been investigating the possible production of silicious ore in the mining district adjacent to Ashland; this material is required as flux for the copper ore being treated by the smelter of the Mammoth Copper Co. from their own mine. The transportation rates from Ashland to the Kennett smelter on that class of ore is $2.40 per ton in carload lots. The smelter makes no charge for treating this silicious ore and pays 75% of all the values contained, and cash is paid for the ore within forty-eight hours after it arrives at the smelter. Shipments as small as 10-ton lots are received. The cost of mining is from 50c. to $2 per ton, according to the hardness of the material and the facilities for mining. The cost of hauling a distance of five miles to the railroad is $1 per ton. This makes it possible to realize a fair profit on low-grade ore. The Kennett smelter is owned and operated by the Mammoth Copper Mining Co., and has a capacity of 1,000 tons per day and the plant is being enlarged to double that capacity.

WASHINGTON.

(Special Correspondence).—The Spokane Mining Exchange has been reorganized and is again working under the rules which formerly governed it. Activity in stocks is stronger now than for several years, and brokers report good business. The exchange meets at 11 o'clock each morning in a private office, but if it continues to be popular, better quarters will be secured.——The stockholders' meeting of the Tamarack and Chesapeake Co. was held in Spokane Saturday, June 2, and an adjournment taken for one month. There is a fight for control between R. Day and H. B. Brien. The latter is president and manager of the company. The Day crowd contends that Brien has not managed the property well, although carload shipments were made which returned 70% lead and 50 oz. silver per ton.——Patrick Clark, president of the Furnace Creek Copper Co., has returned from New York to Spokane, and says construction of a 200-ton smelter at the company's property in Death Valley, Cal., will be commenced this fall. John W. Gates is said to have recently purchased a large interest.——The Spokane Petroleum Co. is boring for oil near Lubec, Mont., and expects to strike oil within 500 ft. of the surface. The company is composed chiefly of Spokane men; Chas. Garber is president.——Jay P. Graves has lately acquired a controlling interest in the Holden mine in the Chelan district, Washington, and he and N. G. Blalock of Walla Walla have secured water power on Chelan river, and it is said will develop this power, build an electric line from Chelan to Spokane, and equip the mine. It is claimed 100 miners will be employed.—— The Oro Plata Mining & Development Co. held its annual meeting in Spokane recently and elected G. W. Simpkins president and general manager; G. H. House, first vice president; M. N. McLeod, second vice president and secretary, and C. K. Laurence, treasurer. The property is 25 miles from Butte, Mont., and lies on both sides of the Copper Chief, which is undergoing development.——The annual meeting of the Albion Mining Co. was held in Spokane June 2, and Thos. Hooker chosen president. This property is at Ainsworth, B. C., and has lain idle for a number of years. Recently the company made a contract with the Black Diamond Tunnel Co., and the Highlander Co. to construct a cross-cut tunnel from their lower level to the south line of the Albion, a distance of 230 ft., thus allowing the Albion the right to cross the Highlander property and use the latter's tunnel, which cost $60,000, and will enable the Albion at a distance of 1800 ft. to tap its vein at a depth of 1000 ft.——D. C. Corbin has commenced work on his coal properties twelve miles south of the Canadian Pacific line, near the Crow's Nest Co.'s holdings in East Kootenay, B. C. Considerable preliminary work will be done this season. Mr. Corbin has 16 square miles of coal land under lease. He is building the Spokane International railway to connect Spokane with the Canadian Pacific.——A bond of $100,000 has recently been taken on the Gladstone property on the Smilikameen in Okanogan county. Spokane people are the owners of the Gladstone and also the American Copper Co., which owns property adjoining the Gladstone and is being developed.

Spokane, June 9.

Special Correspondence.

DENVER, June 11.

Colorado is not generally reckoned as a placer-mining region. While it is true that the first mining done in the State was alluvial, following the rule of nearly all new countries, still the lodes so quickly outstripped the placers in importance that the State became known for its gold and silver veins way back in the day's when California and Montana and Idaho were busy giving nervous thrills to the world with their production of river gold. It may surprise some people to know that Colorado has one of the largest gravel mines in active operation south of Alaska. The mine at Granite, generally known as the Twin Lakes Placer, has two six-inch giants running under 350-ft. head of water continuously against a bank of soft gravel from 80 to 100 ft. high. The season lasts from early May to November. About 160 acres has already been washed and there are about 1,800 acres left to wash. The property belongs to an English company and is operated in a very quiet way. An Englishman named J. Loggin is superintendent and he is better known as a champion rifle shot than as the manager of a placer mine. The ground so far washed has averaged 10c. per cu. yd. Speaking of these matters, brings to mind the so-called placer mines at Hartsell on the Colorado Midland. These deposits have been called alluvial deposits by the local press, but they are nothing of the sort. I was fully informed of this deposit last November by the man who, thus far, has made the only real thorough examination, but at his request I have said nothing of it. So much that is untrue has been published in the last few days, however, that I think I am free to correct some wrong impressions. This deposit is a huge mineralized dike or overflow of rather soft tufaceous rock. It has been extensively mineralized with gold, and the gold is in the amorphous or 'rusty' form, usual to such formations. It will cyanide readily but does not amalgamate at all well. This sort of an occurrence is not at all unique. The huge dike at Ely, Nevada, is gold-bearing on its northeast end and copper-bearing on its southwest end. There is a similar gigantic mineralized dike about midway between Helena and Butte in Montana; I forget the name of the district. Jim Breen owns about 1,200 acres of it and F. Augustus Heinze owns most of the balance. There is also such a dike on the Clearwater near Grangeville, Idaho. When the newspapers speak of a mineralized dike of $3 ore, one mile wide and four miles long, they give the impression that it is all ore. Such is not the case. These huge dikes have great, irregular bodies of ore in them, but, of course, they are not "all ore." Some time they will be profitably worked. Ely was a failure, as a gold-mining proposition. Heinze has never had the nerve to tackle his proposition. The Atlantic and the Evergreen at Grangeville are making a brave struggle with fair hopes of success, but nothing is proved yet; so the past history of these huge dike propositions simply warns us to go slow before we count up the millions of profits in this so-called new thing at Hartsell. As a matter of fact it is not at all new, but the papers have just learned that it exists. I remember camping overnight with a Hartsell prospector in 1891 and viewing his claim. I was too young to know a mine from a hay-stack then, but the prospector was just as sure he had the biggest mine in the world in 1891 as any 1906 prospector is sure of the same thing today. There seems to be a very fair show that some of the larger orebodies at Hartsell may be worked at a profit. If so it will be a great thing for the State.

DENVER, June 10.

The Gunnison tunnel is driven for a distance of 13,000 ft., and the work is being carried steadily forward. The tunnel, when completed, will be about six miles long, and will, it is estimated, carry sufficient water to irrigate 40,000 acres of land in Delta county. It is expected that the work will be finished in 1907, and already the farm lands of Delta and Montrose counties are rapidly appreciating in value. The stimulating effect of the enterprise is adding to the population of the Western slope, and it is stated that every acre of the irrigable lands to be watered through the tunnel has been flied upon by bona fide settlers.

Thomas F. Walsh, formerly owner of the Camp Bird mine, in Ouray county, is taking an active interest in determining the extent and value of the South Park gold discoveries. Mr. Walsh and John W. Benson, who managed the Camp Bird properties under Mr. Walsh, contemplate mining and reducing the ores of South Park on a large scale, provided present indications are realized by development.

An aerial tramway, 13,000 ft. long, is projected to carry tourists from Silver Plume to the top of Leavenworth mountain. Work has been commenced at Silver Plume and it is proposed to have the tramway in operation early in July. The enterprise is backed by Eastern capitalists and their plans contemplate the erection of a summer resort on the mountainside, and other attractive features.

It is stated that plans have been matured by Otto Mears to operate his railroads that radiate from Silverton, through the winter. The report is that Mr. Mears has already entered into contracts to transport the ores from Red Mountain and Animas Forks districts next winter. Preparations to control the snowslides prevalent along these routes are now under way. The first cost of necessary snow-breaks and sheds will be large, and the project to maintain communication with the high altitudes of the San Juan, during the winter months, is of great moment to that region. Should the undertaking prove successful, a large part of the objections often heard against mining in the San Juan will be overcome, and that region will attract many investors who now hesitate to combat the rigorous winters.

It is stated that the dredge-boat of the Reliance Gold Dredging Co., operating in French Gulch near Breckenridge, is taking out $1,000 per day, and that the richest part of the placer ground has not yet been reached. There is unusual activity and a renewal of interest in the placer mines of Summit county. Continued development of the Flossie vein recently cut by the Vidler tunnel of the Transcontinental Transportation & Mining Co. has disclosed an unusually large body of smelting ore. The shoot is over ten feet wide, the larger part of which is of a smelting grade averaging between $40 and $50 per ton, in gold, silver, and lead. The Vidler tunnel is being driven continuously to explore at depth veins that have produced heavily from near the surface. The Raymond mine, near Ohio City, in Gunnison county, which was partly developed several years ago and remained idle for a long time, has been developed into a producer and equipped with an amalgamating and concentrating plant which has been in operation since last fall. It is reported that a large tonnage of ore has been developed and that the mill is making a large and profitable output.

A searchlight of great power is to be placed on Pikes Peak this week. It is confidently expected by the projectors of this attraction—the cog-wheel railroad operators—that the light will be seen from Denver and other distant points.——The Ophelia tunnel, in Cripple Creek district, is becoming the scene of considerable activity. Since the phenomenal ore-shoot opened through the tunnel in the Work Co.'s ground, has been producing, a number of parties have secured leases and are exploiting various veins cut by the tunnel. The rich shoot (which produced $50,000 in May), was found by following a small, vertical vein to its junction with what is known as the Gold Hill flat vein. Prospectors are now proceeding on the theory that a large number of the verticals, whether barren or payable, lead to rich shoots in the flat vein. As this theory has been successfully followed in several instances in Gold Hill, it would seem that a fair average of strikes will be made through raising from the Ophelia tunnel. The Cresson mine of the Bull Hill Mining & Leasing Co. is opening up new bodies of ore. Under the management of Richard Roeloff it has become a constant shipper and a profitable mine.

TORONTO, June 2.

The Ontario Bureau of Mines announces that shipments of ore from the Cobalt district to the smelters, for the three months ended March 31, amounted to 360 tons. The silver contents aggregated 580,825 oz., being an average of 1,613 oz. per ton, valued at $362,248, and the cobalt contents amounted to ten tons, of the value of $10,360. Since shipments of ore began in the latter part of 1904, the total value of the ore shipped approximates $2,250,000.

As a result of the recent dynamite explosion and fire, writs covering about 80 claims for damages have been issued by the owners of property destroyed against the Ontario Powder Co., of Kingston, Ontario, and the George Taylor Hardware Co., of New Liskeard, who are held responsible for the storage of the explosive in the town. The total amount of the claims is about $28,000.

The excursion of members of the Ontario Legislature to the Cobalt camp and the region farther north, left Toronto on May 29. About 60 legislators and a number of journalists and other invited guests made up the party. Mr. Frank Cochrane, Minister of Lands, Forests and Mines, and three other members of the cabinet accompanied the excursion, which was something unique in the way of a legislative trip, owing to the fact that no liquor was (officially) provided. At Cobalt the party visited the Timmis, or La Rose, and Trethewey mines, at the former of which a timely discovery of a new rich vein had just been made. It is about five inches wide on the surface. A nugget was also exposed, the contents of which were estimated at 100 lb. of almost solid silver. Some of the visitors went on to the end of the Temiskaming & North Ontario road, 52 miles north of New Liskeard. The excursionists returned to Toronto on June 1.

Owing to the interest excited by Cobalt developments, gold mining operations in northwestern Ontario have attracted but little attention. Nevertheless considerable activity is being shown in this field. At the Redeemer gold mine in the Wabigoon district work has been resumed under the direction of Superintendent Eames, and extensive development is projected. The shaft is now down 225 ft. and a cross-cut is being run at the 200-ft. level for several hundred feet north, to tap two large veins. On one of these a 200-ft. shaft will be sunk. At the Lost mine immediately adjoining, a shaft will be put down 100 ft. At the Laurentian mine in the Kenora (formerly the Rat Portage) area a 20-stamp mill has been installed. Five stamps are being put in at the Olympia mine in the same locality. American capitalists are actively looking out for chances of profitable investment in this region. J. W. Keenan, of Detroit, recently purchased two gold locations in the Wabigoon area. A number of mining divisions have been established under the new Mines Act. These include Sudbury, Port Arthur, Fort Frances, Temiskaming, Sault Ste. Marie, and Kenora. For each of these a recorder will be appointed, so that applications for mining locations can be made on the spot instead of at Toronto.

The Klondike Water Supply Co. has been incorporated with $6,000,000 capital to bring water for hydraulic mining from the Klondike river to Bonanza, Hunker, Eldorado, Gold Run, Sulphur, and other creeks. The incorporators are Alex. McDonald, Dr. Wm. Barrett, and A. B. Palmer, of Dawson, Robert Kelly, of Vancouver, and Alfred Hitchcock, of London, England. The details of the arrangement by which the Yukon Government and several Yukon mining companies secured the services of C. M. Hatfield, the Los Angeles rain-maker, have been made public. Hatfield contracts to increase the rainfall in such parts of the Yukon as may be indicated by the Rainfall Board, a body to be nominated partly by the Yukon commissioner and partly by himself. If he succeeds, in their opinion, he is to get $10,000—if he fails, he gets only his expenses, including transportation to and from Los Angeles. He was due at Dawson on May 1. The Government has been subjected to a good deal of ridicule for engaging his services.

CALUMET, June 2.

Exploratory work will be started in a few days on the old Carp Lake mine in the Porcupine Mountain copper range of Ontonagon county. E. E. Boalt of Cleveland, O., will have charge of operations. He arrived a few days ago and left for the mine with a crew of men. H. L. Payne of Cleveland, who is interested in the property, will arrive at the mine in a few weeks. The Carp Lake property is in the same section as the Nonesuch, which recently passed into the control of the Calumet & Hecla Mining Co. Arrangements are being made for the exploration of the property by means of diamond-drills, a contract for the work having been let to Cole & McDonald of Duluth, large operators in the Michigan copper district and on the iron ranges of Lake Superior. Like the other properties of the Porcupine Mountain district, the Carp Lake is opened on conglomerate sandstone in which the copper is exceedingly fine, though freely disseminated through the rock. Estimates of the copper contents run as high as seven per cent. The metal is in thin flakes, which float on water, and it is the belief of the owners of the property that the metal cannot be saved by any ordinary process of concentration. The vein is seven feet wide, practically the same as at the Nonesuch, and dips at an average of only 26°. One shaft has been opened to a depth of 350 ft. Alfred Meads of Marquette, an authority on the history, geology and mines of Ontonagon county, is of the belief that the Carp Lake copper is not too fine to be saved by the machinery now in general use. He says it is not flake copper; maintaining that it is granular and will not float, though easily carried away by a strong stream of water. Mr. Meads is of the opinion that a mistake has been made in sending much of this ore to the mill, as some of it runs as high as 40% copper, and should go direct to a smelter. Whatever may be the ultimate result of the Calumet & Hecla's work on the Nonesuch, the mine will receive an efficient test. The solution of the problem of saving the Nonesuch copper would mean equally important results to the Carp Lake, as the two properties are similar in the nature of their copper deposits. There are mines in the Lake district which are operating lower grade copper ore than that traversing the Nonesuch and Carp Lake properties, and

they are earning substantial profits. There is no question about the copper content of the ore of Porcupine Mountain district, it is simply a question of recovering the copper. More difficult problems than this have been solved in mining practice.

Rapid progress is being made in the erection of the new steel shaft and ore-house at No. 3 shaft of the Wolverine mine. The frame-work of the structure is up and the building is being inclosed. In the meantime the skip-road is being improved and rebuilt. Crossties are being used, instead of stringers, as formerly. —— A new copper property near Blanc river, in Cobden township, Ontario, is being opened. Three test-pits have been sunk on the outcrop of a vein of copper ore 12 ft. wide. In addition to copper, the ore carries a small amount of gold and silver.—— Work in the Rhode Island mine is confined to operations in the drift which is being driven north on the West vein at the tenth level. This drift is now 625 ft. The vein averages six feet in width and shows a small amount of copper. At the eighth level, 1,000 ft. below the surface, drifting north was stopped some time ago, after penetrating 1,336 ft. Stoping was carried forward there for some time, but the lode was not uniform enough to warrant the continuance of the work. The tenth level is now entering the ground in which the best results were secured on the eighth level.

At No. 1 shaft, of the North Kearsarge branch of the Osceola Consolidated mine, work is under way on the installation of a new type of skip which is expected to eliminate the trouble that has existed there. Ore shipments from the other openings of the mine will be increased so that there will be no change in the mine's total yield.—— Automatic-dumping steel cars are now in use in shipping ore from the Mohawk and Wolverine mills, on Traverse bay, to the plant of the Michigan Smelting Co. on the south shore of Portage lake. The use of these cars recently succeeded the packing of mineral in box-cars, which, in turn, followed the more antiquated method of shipping it in barrels.—— At the King Phillip property, situated on the line dividing Houghton and Ontonagon counties, and adjoining the Winona on the south, the shaft has been sunk through the overburden and is in rock. The shaft is 14 by 25 ft. and around the collar the earth has caved to a depth of 20 ft. It is planned to drive planks down vertically inside the shaft to rock, in order to stop further flow of the sand down the outside of the shaft, whence it boiled in beneath the timbers and up into the shaft. The new hoisting engine for No. 1 shaft has been delivered at the Winona spur of the Copper Range railroad and will be hauled the remaining mile by teams.

CALUMET, June 10.

The Tyrone Development Co., capitalized for $300,000, has been incorporated under the laws of Minnesota by Lake Superior mining men, and will acquire and develop copper properties near Silver City, New Mexico. The only stockholders are the persons mentioned in the articles of incorporation. The directors are: Thomas F. Cole, John D. Clarke, James L. Norman, Lee W. Farmer, James Wanless, W. W. Billson and Chester A. Congdon, all residents of Duluth. Cole and Congdon are directors of the Calumet & Arizona, Butte Coalition and other large copper corporations. It is said that the new concern will acquire and develop the Burro Mountain property, near Silver City. I. L. Merrill, formerly superintendent of the Calumet & Arizona mines at Bisbee, Ariz., is at present the owner, and the work will be conducted under his management. The general offices of the corporation will be located in Duluth, but there will also be offices at Pittsburg, Pa.

Diamond-drill explorations have been started by the Isle Royale Co. on the Isle Royale lode in its land between Section 11 and the southern workings of the old Huron mine. The result of driving in this direction from the new shaft is promising, and if similar conditions are found in the diamond-drill holes a new shaft will be started for permanent operations.

Some work is being done in No. 5 shaft of the Tamarack mine, but the water which accumulated in the workings during the suspension caused by the fire, still prevents production. It is expected that the shaft will be drained sufficiently by the end of the week to permit ore shipments to the mill. It is expected that shafts No. 1 and 2 will be in shape to resume production in a few weeks. In the meantime No. 3 shaft, at the North Tamarack branch, continues production on an enlarged scale.

A. J. Youngbluth, secretary, has issued a circular letter announcing that the twelfth annual meeting of the Lake Superior Mining Institute will be held in the copper country, on August 8, 9, and 10, 1906. Local committees are arranging a program for the entertainment of members and guests who attend. The last meeting held in this section was in March, 1901. It is expected that a great many prominent mining men in the Lake Superior copper and iron districts, who are members of the association, will attend the meeting and other mining districts of the country will be represented by prominent men.

Preparations for the exploratory work will be conducted on the old Nonesuch mine in Porcupine Mountain copper range of Ontonagon county for the Calumet & Hecla Mining Co., and are progressing rapidly. Considerable machinery has been delivered at Ontonagon and indications are that work will be conducted on an extensive scale. Charles S. Smith of Oconto, Wis., has arrived at the property to take charge of the work. Cole & McDonald of Duluth, who have the contract for the diamond-drill work, have part of their outfit on the ground. Two drills are to be used and a thorough test of the Nonesuch will be made. In addition, some of the old shafts will be unwatered. These openings are down a few hundred feet and will permit an examination of the ore at that depth. If the prospects are favorable, it is likely that some of the openings will be extended. Some of the old buildings on the Nonesuch have been repaired to accommodate the men to be employed by the Calumet & Hecla Co. and by Cole & McDonald.

Work of equipping the new stamp-mill of the Victoria Co. in Ontonagon county is practically completed, and the machinery will be tested this week. The ore bins are full, but some minor adjustments of the working equipment will be made before the plant is placed in regular service. The mill is built substantially and equipped with modern appliances for concentrating the copper. One head is installed, and there is room for another. While it has never been claimed for the Victoria that its ore is rich in copper, the openings underground show fairly good mineralization, and it is believed that the low operating costs resulting from the hydraulic power plant will admit of good profits. There is a large tonnage of milling ore blocked out in the mine.

Sinking in the shaft on the property of the Lake Copper Co. in Ontonagon county has passed the fourth level, 400 ft. beneath the surface, and is under way to the fifth level. Sinking has been in good copper ground continuously since work was resumed by the present organization and 50 ft. of good 'stamp rock,' with mass and barrel copper, have been opened. Diamond-drill work on the Lake Co.'s property has reached a depth of 1,000 ft. Preparations are being made to start a second bore in the series which will be drilled to obtain a cross-section of the property. There is little overburden where the second hole is to be started and no difficulty should be experienced with the work there; but at other points the overburden is excessively heavy, and because of this condition it may be decided to rig up a larger outfit at the first hole and bore to greater depth. In this manner the same results would be secured as by the more difficult process of putting a new hole down through the heavy overburden.

The Northern Ontario Copper Co. is meeting with success in its efforts to open a copper mine at the Leziert and Bronson property, near Dean Lake, Ontario. It has a well-equipped camp with 20 men at work there. Night and day shifts are employed and the shaft is being sunk at the rate of three feet every 24 hours. Six substantial buildings have been erected where four months ago was only a forest. There have been installed and are in operation two boilers, air compressor, two machine drills, hoisting engine, etc. A dam has been built across a stream near the shaft house to provide a water supply. The shaft is nine by sixteen feet in size, and is down 72 ft. Over 1,000 tons of shipping ore is on the dump, and shipments will be started next week. It is planned to start cross-cutting and drifting on the 100-ft. level of No. 1 shaft, and connect with the shaft on the Bronson location. The company has 280 acres of mineral land and will ship its ore over the Canadian Pacific railway, which has tracks to within one and three-quarters mile of the mine.

SALT LAKE, June 11.

Several additional damage suits were filed against smelting companies, operating at Bingham Junction and Murray last week, the complainants being farmers owning property in the vicinity of the smelters. A committee of three, representing a large number of farmers, asked the county attorney to take steps to have the smelters declared a nuisance and ordered closed unless the fumes be rendered harmless to vegetable life. The committee contended that greater damage has been done to crops this year than ever before, owing to damp weather. The attorney stated that he would make an investigation of conditions personally before making a move one way or the other. The agitation and the multiplicity of suits, now pending in the courts, has brought the smelting companies face to face with a serious question. Some managers declare it would be as cheap for the companies involved to move their plants to a site remote from the farms. It is not unlikely that the day will come when these plants will be concentrated somewhere near Garfield, the site of the American Smelting & Refining Co.'s new plant and the concentrating mills of the Utah Copper and Boston Consolidated mines.

Prospecting of the West Quincy mine at Park City by means of core-drills from the 440-ft. level is about to begin.——At the close of last week the Daly-Judge Mining Co. had outstanding bonds amounting to $32,000, which will be called in and cancelled before July 1. John J. Daly, the president, also stated that on January 1 last the company had a bonded indebtedness of $209,000 and $22,000 in an overdraft. The company has earned from $70,000 to $75,000 monthly from the sale of ore and concentrate, and has paid off bonds on an average of $45,000 monthly. The expense of operation has been between $23,000 and $25,000 per month. Both the ore and concentrate shipped ran about $45 per ton. The mill is treating 175 tons per day, making a saving of 90 %. A satisfactory contract has been obtained from the American Smelting & Refining Co. The ore carries a heavy percentage of iron and with the lead present forms a suitable flux for the silicious ore coming from Nevada.——A meeting of the board of directors of the Thompson Mining Co. operating at Park City will be held this week. The question of resuming work will be discussed.——The directors of the Daly-West Mining Co., at Park City, have ordered payment on June 15 of the regular quarterly dividend of $108,000.

An examination of the Southport mine, at Stockton, has been in progress for several days for the prospective purchaser of a large interest.——A drift has been started from the 1,000-ft. level of the New Stockton mine, at Stockton, to tap the Catherine fissure.

The shipment from the Tintic district last week aggregated 144 carloads, the shippers and amounts being: Gemini, 26; Centennial Eureka, 35; Eagle & Blue Bell, 7; Uncle Sam Consolidated, 5; Beck Tunnel Consolidated, 7; Yankee Consolidated, 3; Bullion Beck, 11; May Day, 2; Eureka Hill, 3; Black Jack, 3; Mammoth, 3; Carisa, 2; Grand Central, 4; Scranton, 3; Dragon Iron, 23; other mines, 6. The Tintic district has more shippers than any other camp in the State. The Grand Central, Mammoth, Victoria, Swansea and Uncle Sam Consolidated companies announced dividends this week for June of $15,000, $20,000, $12,500, $5,000 and $5,000 respectively.——Late developments in North Tintic are interesting and indications are favorable for the opening of some good mines there.

There is a possibility of the re-organization of the Ohio Copper Co. with a strong syndicate of Eastern capital in control. The mines of this company have been examined recently by Thomas Weir, former manager of the Highland Boy (now Utah Consolidated), Duncan MacVichie, manager of the Bingham Consolidated and Alfred Frank of Butte. If the company is not re-organized, there will be, at least, a bond issue.—— The Bingham canyon mill of the Utah Copper Co. is treating 600 tons of ore daily, and during the month of May produced 1,000 tons of concentrate, on which was realized nearly $100,000.——The mineral opened recently in the northeast part of the Utah Consolidated mine, at Bingham, according to R. H. Channing, manager, is the largest ore-shoot opened in the property. The ore carries from 7 to 10% copper and about $12 gold.——The compressor plants recently ordered for the New England Gold & Copper and Last Chance mines, the latter owned by the Nevada Utah Mines & Smelters Corporation, have been installed.

The organization of the Caliente & Pioche Railroad Co. has been announced with the San Pedro, Los Angeles & Salt Lake Co. in control. The road will be 30 miles long and will follow the grade built many years ago. It is said there will be no delay in getting the work started. The Nevada Utah Mines & Smelters Co. is said to have deposited $80,000 to the credit of the San Pedro, Los Angeles & Salt Lake Co. to encourage early construction and as a display of good faith. This amount is to be returned in the shape of deductions from freight charges.——The Utah Copper Co. has placed an order for 1,104 vanners with the Union Iron Works Co., San Francisco, for the new Garfield mill, now being constructed. The General Electric Co. will supply the electrical equipment, which includes two 2,000-h.p. steam-driven generators and about 30 motors, of various sizes.——It has been announced by an official of the Garfield smelter that some of the furnaces of the new plant will be blown in within the next ten days.

C. A. Short, of Fay, Nevada, manager of the Jennie Gold Mining Co., at Goldsprings, Utah, will soon be in the market for a mill.——The May ore and bullion shipments for the mines of Utah, as reported through the Salt Lake banks, aggregated a total of $1,918,350.

——The Garrison and Monster groups in the Deep Creek region have been consolidated, forming the basis for the organization of the Garrison-Monster Mining Co.

——The Continental Transportation Co., Henry M. Crowther, manager, has practically completed the survey of a railroad into the camp of Alta. The old line, formerly operated by the Rio Grande, was leased by Mr. Crowther for the Continental Co. several months ago. He states that trains will be operating into Tannerville, five miles below Alta, within eight months.

BUTTE, June 10.

The Amalgamated Copper Co., North Butte and Red Metal Co., the latter the successor of the Heinze interests in Butte, have made their annual reports to the tax authorities, showing the gross and net proceeds of operations during the year ending June 1. The net earnings of the Amalgamated companies amounted to $13,805,811.67, which is an increase of $5,113,568.15 over the previous year. The Parrot Co. alone showed a decrease, while the Washoe again showed that all of its earnings were spent in smelter improvements, machinery purchases, etc. The Anaconda Co. made a remarkable showing, its increase over last year in net earnings being $1,233,878. The following table gives some interesting figures on Amalgamated operations:

	Anaconda.	Washoe.	Parrot.	Trenton.	B. & B.	B. & M.
Tons ore extracted	1,521,310	95,210	163,569	168,770	246,593	1,209,805
Gross proceeds	$16,613,537 01	$1,146,981 03	$1,397,406 82	$1,549,099 43	$2,821,319 49	$15,509,832 05
Cost of mining	5,525,320 52	412,723 59	596,508 75	492,552 82	866,357 81	4,182,508 24
Freight on ore	231,999 75	19,042 02	29,442 42	25,315 47	49,318 62	1,129,547 14
Cost of reduction	3,457,007 38	260,288 48	353,158 54	353,280 40	509,028 03	2,958,666 43
Marketing charges	1,645,943 94	97,764 35	141,281 75	136,422 20	320,722 24	1,081,000 68
Total	$10,860,271 59	$1,322,702 25	$1,120,391 46	$1,007,570 89	$1,745,426 70	$9,351,722 49
Net proceeds	5,753,265 42	.....	277,015 36	541,528 54	1,075,892 79	6,158,109 56

A comparison of the net proceeds of the properties owned or controlled by the Amalgamated Copper Co. for the last two years follows:

	1904-1905	1905-1906	Increase.
Anaconda	$2,259,693 73	$5,753,265 42	$3,493,571 69
Parrot	328,106 69	277,015 36	*51,091 33
Trenton	70,110 22	541,528 54	471,418 32
Butte & Boston	178,712 81	1,075,892 79	897,179 98
Boston & Montana	5,855,620 07	6,158,109 56	302,489 49
Total	$8,692,243 52	$13,805,811 67	$5,113,568 15

*Decrease.

The total net earnings of the Amalgamated companies was almost double the net earnings reported the year before, the latter having been $6,240,024, apportioned as follows: Anaconda, 1,259,875; Parrot, $233,964; Trenton, $74,832; Butte & Boston, $96,853; Boston & Montana, $4,574,498.

The Red Metal, North Butte, and Alice companies have reported as follows:

	Red Metal M. Co.	North Butte.	Alice
Tons of ore extracted	149,101	259,650	3,831
Gross proceeds	$1,929,568 17	$5,480,545 24	$31,524 81
Cost of mining	587,460 66	1,160,766 21	.....
Freight on ore	89,460 60	52,017 23	.....
Cost of reduction	587,696 51	1,255,753 04	.....
Marketing charges	223,651 50	.....	.....
Improvements	.....	1,164,000 00	.....
Total	$1,488,269 27	$3,632,536 48	$37,396 51
Net proceeds	441,298 90	1,848,008 76	.....

The Red Metal Mining Co.'s net proceeds are for the period from February 1, 1906, to June 1, 1906.

An interesting fact about the former Heinze mines (Red Metal) is that regularly for a number of years Heinze reported net earnings at $600,000 annually, while the new owners, without increasing the output, report net earnings of $441,298 for four months.

The Butte district in May produced 33,881,450 lb. copper. The Anaconda and the Boston & Montana had a material increase both in ore production and copper. There was a falling off at the Parrot, due to interruptions caused by sinking and exploration work. As a new body of ore has been opened on the 1,800-ft. level, the output is likely to be better in June.

The total tonnage of ore and the production of copper for May are shown in the following table:

Company.	Tons of ore.	Pounds of copper.
Boston & Montana	124,000	8,680,000
Anaconda	130,200	8,983,800
Butte & Boston	20,150	1,309,750
Washoe	15,500	976,500
Parrot	12,400	818,400
Trenton	16,120	1,209,000
North Butte	27,900	3,224,000
Butte Coalition	49,600	3,092,500
Original	27,900	2,092,500
East Butte	6,200	558,000
Raven	4,030	443,300
Pittsburgh	3,100	223,200
Total	561,900	33,881,450

The Davis-Daly Estates Copper Co., recently organized by J. A. Coram and associates, will shortly begin operations in Butte district, as a contract has been made with the Original Mining Co. to run a cross-cut 3,500 ft. from the 1,800-ft. level to the Original mine. The Davis-Daly Co. owns 400 acres of ground in the heart of the district, much of it being in the business section of Butte. In the group there are ten claims that have been developed. The mines purchased from the Daly estate have not been worked since the death of Marcus Daly. Several of the Daly mines were good producers of silver at the time work on them was stopped. All of the properties of the Davis-Daly Co. adjoin, or are near, some of the big producing mines. A number of the claims lie just south of the Anaconda, Parrot, Original, Gagnon and other mines of the Amalgamated Co., and it is expected that by the long cross-cut to be driven from the Original a dozen or more veins will be cut at a depth of 1,800 ft. A shaft will be sunk near the end of the cross-cut in the southern part of the district and will connect with it. Another shaft will be sunk on the Hesperus and a cross-cut driven north. Some of the Davis mines will be reopened and it is expected that with a little preliminary work they will become productive. The Davis-Daly Estates Co. is the most important mining corporation formed to operate in the Butte district since the organization of the North Butte Co. The directorate includes F. Augustus Heinze, Henry Mueller, M. S. Largey, L. S. Gillette, C. R. Leonard, John MacGinniss, G. W. Davis of Butte; C. K. McCornick of Salt Lake, Karl J. Roebling of Trenton, N. W. Bumstead and J. A. Coram of Boston.

In a report to the stockholders of the Raven Mining Co. John Berkin, general manager, describes the progress made in development during the past twelve months. No mining was done in the Raven, all development and operations being confined to the veins that apex within the boundaries of the Snoozer claim. The work was done on the Snoozer because of its proximity to the extensive orebodies of the Mountain Consolidated properties of the Amalgamated Co., and also because the company was able to secure a lease on the Buffalo shaft of the Anaconda Co., through which it was enabled to develop the veins of the Snoozer to greater depth and more economically than would have been possible through the workings of the Raven Co. During the year the company cut 5,780 ft. of levels, crosscuts, drifts, and raises. On the upper levels the veins are of little value, but important orebodies have been discovered on the 1,200 and 1,500 levels of the Snoozer. A good grade of ore is being mined on the 1,200-ft. level, and on the 1,500-ft level the same orebodies are found to be larger. The company is shipping 130 tons of ore per day, which will be increased to 200 tons. The average yield is 4% copper, 10 oz. silver and $1.50 gold per ton. It has become necessary to construct a number of levels between the 1,200 and 1,500-ft. levels to open the orebodies more extensively. Below the 1,500, levels will hereafter be driven 100 ft. apart.

At a meeting of stockholders and directors held in Butte, the following officers of the Raven Co. were elected: William D. Thornton of Butte, president; John Berkin, of Butte, vice president and general manager; Charles Mattison, of Butte, secretary and treasurer; E. C. Frisbie, of Hartford, C. J. Root, of Bristol, Charles E. Morris, of Pony, Mont., Charles Schmidt, of Butte, directors, in addition to the other officers, who are also members of the board.

The condition of the Parrot mine is improving. At the annual meeting, while no official report was made, John D. Ryan, managing director, made a statement to the effect that the mine was again showing up encouragingly. A new orebody was opened on the 1,800 level, and while the ore is low grade it is better than the bulk of that the company has lately been shipping. Mr. Ryan said the operations last year were not so profitable as could have been wished, due mainly to the Heinze litigation which prevented the company from mining on what it claimed to be its veins, and which resulted in a suspension of operations for some time. At a meeting of stockholders of the company held in Butte, the old board of directors was re-elected. The by-laws were changed so as to permit the directors to meet in Boston or elsewhere.

The Reins Copper Co. stockholders voted to change the place of the annual meetings to Pittsburg, nearly all the directors being Pittsburg men. The company has met with disappointment in its search for veins at a depth of 1,200 ft. It is expected that within 80 ft. to the north of the shaft a vein would be cut, as a small one was opened at the 800-ft. level, 40 ft. from the shaft, but the cross-cut has been driven 130 ft. without enccuntering a vein. The south cross-cut is in 60 ft. and nothing has been found in that direction. The Reins mine is situated east of, and adjoins, the Leonard mine of the Boston & Montana Co., and it has been expected that the Leonard vein would be found in the Reins, but some mining men say the vein is faulted near the east end of the Leonard ground.

The shaft being sunk on the Six O'Clock group by the Butte Exploration Co. has reached a depth of 630 ft., of which 110 ft. were sunk in May. The shaft will be sunk to 1,000 ft. before cross-cutting.

The Cable Consolidated Mining Co. has shipped boring machinery to its placer property, and will bore 330 holes, being one on each acre of ground. A new hoist is being put up at the quartz mine and as soon as the machinery and new equipment is in place the output will be materially increased.

At the Butte reduction plant of the Original Consolidated Mining Co. a new blast-furnace, designed for treating ore by a new process in which gas was to be used as fuel was installed for a test. It was given a fair trial but proved a failure and will be taken out, an old-style furnace being put in its place. The plant is treating all of the Clark ore—about 900 tons per day, shipments to the Washoe smelter having been stopped. Orders have been given for the enlargement of the smelter of the Boston & Montana Co. at Great Falls, and when completed the plant will be able to handle an additional 1,500 tons of ore per day. It is now treating 4,000 tons daily.

Two new mining companies were organized in Butte during the past month, one being the Hazel Mining Co. by Butte men; the other, the Daisy Bell Gold & Copper Development Co. This is the third Daisy Bell Co. organized to work this property. The company organized some time ago has an option on the Daisy Bell mine but was unable to take it up. Its promoters claim that an extension was granted and they proceeded to sell stock and expected to take up the option when the new company made its appearance. New York people were interested in the previous organization and trouble is likely to ensue, as charges of bad faith are made, in Butte, against the owners of the property. The latest company is capitalized for $600,000.

The plant of the Montana Zinc Co. has been shut down pending improvements, and the doubling of the capacity of the plant. The company is still receiving ore from the Lexington and Moulton mines.——The Butte Copper & Zinc Co., which owns the Emma and Czaromah mines in the southwestern portion of the city, has let a contract for machinery for the Emma. The Czaromah adjoins the Emma and will be operated through the Emma shaft. There is a large vein running through both claims. Samples from the Emma assay 45.3% zinc, 9% lead, some gold, copper, and silver. The properties will be mined for zinc ore of which there is an abundance in both mines.——The Tuolumne Copper Mining Co. is one of the late Butte organizations. The Tuolumne mine adjoins the North Butte group, and is a fractional claim. It is tied up in the courts in litigation over the estate of James Tuehy, who owned the mine, and it will probably be a long time before the property is released by the courts. The new company represents some of the interests in the Tuolumne, but not all.

LONDON, May 30.

Several important flotations lately are said to have gone off well—so far as substantial underwriting is concerned. One of the most prominent is Great Cobar Ltd. With a capital of £750,000, divided into 150,000 shares of £5 each, and with first-mortgage debentures to bearer of like amount in bonds of varying sums, the Company has been formed to acquire as a going concern a property of this name well-known in New South Wales, consisting of copper, gold, coal mines, coke works, smelting, refining and electrolytic installations. A synopsis of the properties is given in the prospectus, which describes them as being "the largest copper producers in Australia." From 1894 to 1902, 730,669 tons of ore were extracted, which produced 23,922 tons of copper. The present reserves are estimated at 1,530,506 tons, which are expected to yield 40,449 tons of copper. The present price of copper is high, and according to the report of Chas. M. Rolker, which accompanies the prospectus, and which was made so recently as April 5 last and telegraphed, the net profit on the above figures is estimated at £2,346,000. The reports show that at 850 ft. the lode ranges from 60 to 100 ft. in width. The coal reserves are estimated to contain 6,000,000 tons. Most exhaustive reports have been presented, not merely by Mr. Rolker, but by J. D. Kendall, and W. J. Barnett. That of Mr. Kendall describes the property as most valuable, and he is fully satisfied that his estimates with regard to it under proper management will be realized. He found the ore blocked out to be equal in quantity to over seven years' output at the present rate of consumption, and four years' output at the more expeditious rate at which it is in future intended to work. Mr. Barnett, in effect, confirms the views of Mr. Kendall, and the figures with which the report of Mr. Rolker bristles are most encouraging as regards the profits the Company may expect. At the present rate of production—4,000 tons of copper per annum—it is estimated the profits would enable 15% to be paid on the share capital, after providing for the debenture interest, which is at the rate of 6%. The profits would be proportionately increased on the larger scale on which it is intended to work. Subscriptions for £420,000 of debentures and for £116,000 shares, which will give the Company a cash working capital of £150,000 with £200,000 debentures in reserve, have been assured. The price to be paid for the properties, as a going concern, is £1,006,000, of which £800,000 is payable in cash and £55,000 in fully-paid shares, and £151,000 in cash, shares or debentures at the option of the Company. The board is practical and influential. At its head is William Rich, who was formerly general manager of the Rio Tinto mines, and another of its members is Rudolph H. Henning, well known for his deals in Westralian and Mexican mining.

Capital also continues to be found in London, to a moderate extent and in a tentative way, for Cornish mining. One of the newest recruits to the limited liability system is Wheal Kitty in the St. Agnes district. At a meeting of the 'Adventurers' held last week the chairman, J. H. Collins, reported that they were asked at the last meeting, as pursers, to see whether there was a feeling in favor of carrying on under the cost-book system, and they were authorized, if so, to issue 1,000 additional shares at the price which had then been paid up. A number of people in Cornwall, were all very friendly in the matter. They look upon the mine as a good one, but they found, like other people, that the cost-book system does not recommend itself now. Whatever opinions they might have about the goodness of the system, it is very difficult to raise any capital under it. Having put the cost-book system to the test, the pursers now find it is best to take steps at once to convert this Company into one of limited liability. A cash capital of £30,000 is to be raised.

In dealing with the record of the mine, Mr. Collins reminded the meeting that Wheal Kitty was an old mine when Henwood's description was published in 1843, but there are no statistics available as to its production earlier than 1852. Since then the mine has had a checkered career—sometimes very rich—at others poor, but it has turned out more than half a million pounds worth of tin ore in spite of the fact that it has always been worked in a hand-to-mouth fashion. With the enlargement and equipment of Sarah's shaft as a main shaft, and with the provision of boring machinery to expedite the developments, the mine could not fail to have a profitable future. and all this it is intended to do by the aid of the new capital now to be raised. Capt. Prisk reports May 23, 1906: "Vottle, 30 east now in settled country 18 fm. east of the shaft, after passing through two cross-courses, is 3 ft. wide, and assays 28 lb. to the ton. New branch lode in 60 fm. rise, 2 ft. wide, and shows several leaders of rich tin-ore; average value not yet ascertained. Stamps lode has so far yielded 36 tons of ore from a stope above the adit-level about 5 fm. west of the shaft, the assay value of which is 42 lb. to the ton. We have several pairs of tributers working in various parts of the mine at tributes varying from 12s. to 15s. in the pound."

With greater activity in the county, the paucity of skilled miners is becoming accentuated and the young inexperienced men are looking for higher pay. Forty of those employed underground at Dolcoath are said to have struck work for higher wages. The young men in question are not tutworkers, but work on owners' account (so much per shift). They complained to one of the agents that they considered the pay they were receiving insufficient. At an interview with the manager it was stated by the spokesman of the party that they wanted more pay. The manager promptly replied that they would not get it for the same amount of work as they had been doing. He reminded them that they only averaged 17 shifts per month, and that however little time they put in, the working charges of the mine remained the same as if they were working full time. If they were prepared to do what the executive of the mine had for years desired, namely, to work more shifts per month, their rate of pay would be increased in proportion. If they would work 20 shifts per month they would be paid 3d. per shift more than they had been receiving; and if they would work 24 shifts per month they would have 6d. per shift more than they had been receiving. It is since reported that all except nine of the men returned to work, and it is stated that strong measures are likely to be taken in regard to them, as the general opinion on the mine is that there is no real grievance. It is pointed out that if they work a whole month the best of them can earn £4 to £4 10s. per month, which is considered a fair wage, having regard to their experience.

On the other hand hundreds of Cornish miners have returned from the Transvaal. This, while partly attributable to the improved demand for miners in Cornwall, is thought to be also due to the partial paralysis of mining operations in the Transvaal through the shortage of colored labor, so that many new Cornish rock-drills purchased by the Transvaal mines are stored and unused through the uncertainty.

In American mines the market for Stratton's Independence shares has suffered from the influence of a somewhat enigmatical cable from the manager, which has been interpreted as pointing to a falling off in the mine. Whether this is of a temporary or permanent nature does not yet appear. Thus this company, of checkered career, keeps up its reputation for occasionally launching a bolt from the blue, giving some of the newer stockholders the jumps.

A report by Lipson Hancock, the manager of the Wallaroo and Moonto copper mines, situated on Yorkes peninsula, South Australia, is published. It shows that from 1860 to 1905 the mines yielded 1,583,530 tons of copper, to the value of £12,627,000, and paid £1,830,254 in dividends. The total expenditure was £10,770,718, and the average annual expenditure £234,150. The average yearly production was 34,424 tons, and the number of the company's employees in December last was 2,318. The report shows that the Wallaroo brand, which is noted for its purity, commands a ready sale in Europe, India, and China, and that this is the first mining company in Australia to exceed £1,000,000 in dividends.

Inspection of Copper Districts.

After January 1, 1907, the collection of copper statistics for the United States Geological Survey will be in the hands of L. C. Grafton. During the coming summer, Mr. Graton will visit the principal copper camps of the country, including those of the Lake Superior, Bingham, and Butte districts as well as the four great camps of Arizona at Clifton, Bisbee, Globe, and Jerome, and the district about Redding, Cal. Mr. Graton will spend most of the summer at Redding, but will visit the other camps en route to California or Washington, taking in the northern camps on one trip and the southern camps on the other. While at Redding he will make detailed investigations of the geology of the district.

The general geology of the Redding quadrangle has been studied by J. S. Diller, who has written the text and prepared maps for a folio of that area which will soon be published. Within the quardangle, however, are three small but very important copper areas of which special topographic maps have recently been made. These areas are the Bully Hill, Little Backbone, and Iron Mountain districts.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rock from Eureka, Nevada, marked D. K., is Dolomite.

The rock specimen from Carrville, Cal., marked B. No. 1, is Silicious Amphibolite Schist. It contains a quantity of finely disseminated pyrite.

The rock from Carter, Mont., marked K. & Q. Co., is quartz-schist. It is very friable and to the touch seems softer than it really is. The bright, shimmering scales are sericite.

The rock specimen from Austin, Nevada, marked V. W. is quartzite seamed with veinlets of calcite. The rock contains disseminated galena and pyrite, the former predominating.

The rocks from Paris, Kern Co., Cal., are: No. 1, Pegmatite; No. 2, Rhyolite, in which there is distributed a lead-colored sulphide in microscopic crystals—so small as to be undeterminable; No. 3 is evidently similar to No. 1, but much altered. No. 4 is Quartz with a little mispickel (arsenical-iron sulphide); No. 5 is also Quartz containing pyrite and a little mispickel. It is evidently a silicified dike rock; No. 6 is typical Felsite, and contains two per cent or more of extremely fine pyrite.

The minerals from Mercur, Utah, are of unusual interest. No. 1 is Clay, not talc. This mineral will absorb water and can be puddled into a plastic mass—something that cannot be done with talc. The black coloring matter is probably carbon. No. 2 is Kaolin and can readily be reduced to a plastic state. It should be sent to manufacturers of pottery, if obtainable in large quantity, as it may be useful in manufacturing porcelain dishes, insulators and other articles. From the description given of the occurrence of these minerals, it seems likely that a feldspathic rock has been fractured, and movement has taken place along the line marked by the occurrence of the black clay, or gouge. The rock was then altered on either side to white Kaolin by the thermal waters passing upward along the fissure or zone of fracture. No. 3 is largely composed of Cinnabar, associated with calcite, which it has in part, seemingly replaced; No. 4 is principally Stibnite (antimony sulphide). There is also present native sulphur; No. 5 is apparently a much altered country rock impregnated originally with sulphide of iron, and sulphide of mercury, the iron being now altered to limonite and hematite, while the sulphide of mercury, cinnabar, remains practically unaltered; No. 6, Hematite, impregnated with disseminated Cinnabar. The white mineral in this specimen is Kaolin.

Hardening Steel.—There are at present two theories held by two distinct groups of scientists to account for the hardening of steel. These are the carbon theory and the allotropic theory. Briefly, the carbon theory holds that the hardness of hardened steel is due to the fact that the carbon exists in a hard state at a high temperature, and that it is retained in this state by sudden cooling. This condition exists only at a high temperature, and becomes unstable during slow cooling; and at a lower temperature the carbon changes into the carbide found in unhardened steel. Sudden cooling prevents the formation of the carbide and retains the carbon in the cooled steel in the same hardened state as that which existed at the high temperature. The allotropic theory declares that the action is indirect, and that, above the critical temperature, the iron passes spontaneously into a special, strong, hard brittle, allotropic state, which is unstable below that range, but that inasmuch as the passage from one state to another is relatively slow, the iron may be retained in the hard form by sudden cooling. The theory admits that the hardness is dependent on and proportional to the carbon present, and that no carbonless iron presents anything like the hardness of high-carbon steel.

So many eminent scientists are arrayed on each side of this question as to induce the belief that there must be truth in both views. The carbon theory appeals to the mind because it gives a direct tangible reason for the hardness. The chief argument against this theory lies in our ability to conceive of a substance so hard that 1% of it, when mixed with 99% of a substance as soft as iron, could produce the hardness of hardened steel.

Trade Treatises.

The Sullivan Machinery Co., Railway Exchange Bdg., Chicago, has issued a handsome little brochure on coal mining by machinery. Though small, it illustrates completely the machines and methods now used in mining coal and shows the advantages of the new system over the old. Some space is also devoted to churn-drilling and to the diamond-drill in prospecting work. It is one of the most complete small treatises we have seen.

Commercial Paragraphs.

Allis-Chalmers Co., of Milwaukee, have issued Bulletin No. 1,700 on saw-mill machinery.

The Ohmen Engine Co. is making high-grade engines at its new works on 17th and Capp St., San Francisco.

The Standard Oil Co. has ordered two Hornsby-Akroyd oil engines of 25 h. p. each, which will be shipped to Chinkiang, China, and used for pumping purposes. These engines are supplied by the De La Vergne Machine Co. of New York.

The De La Vergne Machine Co. of New York, has issued a new 82-page catalogue describing the operation of the Hornsby-Akroyd oil-engine, giving illustrations and short descriptions of recent installations of these engines. The Hornsby-Akroyd oil-engines are well known, there being over 14,000 in operation.

Automatic Cyaniding Machinery, is the title of the Blaisdell Co.'s latest publication, descriptive of their various types of mechanical devices for automatically and economically handling sand and slime at metallurgical plants. The book is profusely illustrated, showing a number of the large mines where their machinery is installed and in successful operation. It also shows interior and exterior views of the machinery in detail. Issued by the Blaisdell Co. of Los Angeles, Cal.

The Compressed Air Machinery Co. of San Francisco, whose place of business was for several years at the corner of First and Stevenson streets, has been reorganized and incorporated, with P. H. Reardon as president and general manager, W. A. Hewitt retiring. The new company is now located at the corner of Jessie and Ecker streets, between First and Second, San Francisco, where they will continue the manufacture of their Giant machine drills, the Word Bros. drill-sharpener, compressors, and other machines for mining work.

The Production of Lithium Minerals in 1905.

A mistaken impression prevailed in this country for several years that there was a large demand for lithium minerals. The result was over-production. In 1905, however, sharp retrenchment occurred, and the production fell to practically nothing. As reported by E. O. Hovey, special agent of the United States Geological Survey, it amounted to only 21 short tons, valued at $252. All of it came from San Diego county, Cal. In 1904 the output of lithium minerals in the United States had amounted to 577 short tons, valued at $5,155; in 1903 to 1,155 short tons, valued at $23,425. There were no imports of lithium salts into the United States during 1905.

The mines of Pennington county, South Dakota, which formerly produced the greater part of the lithium ore consumed in the United States were entirely idle during 1905. It is not likely that work on them will be resumed before the stocks of ore now on hand have been considerably depleted.

Practically the only minerals which have been mined as ores of lithium have been amblygonite, lepidolite, and spodumene. Amblygonite has been found in commercial quantities only near Pala, San Diego county, Cal. This region is also the only one in the country where lepidolite, or lithia mica, is produced in commercial quantities. The spodumene mines are located in Pennington county, South Dakota.

The principal use of lithia ores is for the manufacture of the carbonate of lithium, which is utilized in the solid form and in solution for medicinal purposes, especially for the manufacture of so-called lithia waters. Lithium salts are used also to a small extent in the manufacture of compounds for the production of colored fire. The metal tinges a flame with a beautiful shade of red.

The C. T. Carnahan Company, of Denver, has given a Murphy air-hammer rock-drill and dust-layer to the College of Mining of the University of California. This is a useful addition to the apparatus at the College and it does credit alike to the enterprise and the generosity of the company mentioned.

Personals.

D. M. Riordan is at Hanover, New Mexico.

John Weir, of New York, is visiting San Francisco.

H. W. Hardinge has returned to Denver from Mexico.

Juan F. Brandes was in London. He is now at Berlin.

M. E. Macdonald, of Guanajuato, is visiting New York.

Martin J. Heller is examining mines in British Columbia.

H. R. Sleeman is on his way from London to the Argentine.

Edward Skewes sails from Montreal for England on June 21.

Charles Janin is on his way back from London to San Francisco.

L. B. Davenport is now at the Mt. Gaines mine in Mariposa county.

Stuart R. Elliott is manager of the Juragua Iron Co. at Santiago, Cuba.

Emerson Gee has returned to his home in Los Angeles from Sinaloa, Mexico.

Frederick J. Siebert is examining copper mines in Fresno county, California.

H. W. Turner has been examining the Black Butte quicksilver mine in Oregon.

C. H. Karns, of Central City, Colo., is now superintendent of the O. K. mine.

J. W. Mercer has returned to New York. He will proceed to Europe shortly.

Arthur W. Stevens, of Chicago, is in Wisconsin examining lead and zinc properties.

William M. Brewer has left Vancouver on an extended visit to mining camps in Alaska.

R. A. Stewart has been appointed manager of the Santiago mines, in Oaxaca, Mexico.

E. F. Gray is mine superintendent for the Nevada Consolidated Copper Company, at Ely.

W. Lawrence Austin passed through San Francisco on his way from Arizona to New York.

Thomas T. Read has accepted a position with the Orford Copper Co., at Camden, New Jersey.

Ellsworth Daggett was in San Francisco during the week, on his way from Los Angeles to Nevada.

W. H. Trewartha-James is examining the copper mines of Phillips River, in Western Australia.

Theodore L. Lammers has organized the Mining & Engineering Development Company at Spokane.

C. M. Fueller has returned to Denver from Douglas, Arizona, where he was engaged on professional business.

F. G. Willis, of the firm of Hills and Willis, has returned to Cripple Creek from southern California and Nevada.

Frank Jenkins, mine superintendent to El Oro Mining & Railway Co., has returned from a trip to the United States.

H. W. Spaulding is now superintendent of Mekka Placer Gold Mining Co., French Gulch, near Breckenridge, Colorado.

Robert T. Hill visited Berkeley after examining copper mines in Plumas county, California. He has returned to New York.

Donald R. Morgan has ceased to be superintendent and has become consulting engineer to the Cia. Metalurgica de Torreon, Mexico.

H. L. Payne, of the Los Angeles assaying firm, The Wade & Wade Co., has gone to the Michigan copper country on a tour of inspection.

E. C. Holden is still at St. Luke's Hospital, Denver, where he is slowly recovering from the fracture to his leg, which is mending satisfactorily.

H. Vincent Wallace left Nogales on June 3, going to St. Louis and Chicago, whence he will proceed to New York, with the intention of extending his journey to England.

R. H. Burrows, of Guanajuato, will be examining mines along the line of the Kansas City, Mexico & Orient R. R. in Chihuahua and Sinaloa during the next three months.

George W. Bryant, J. S. Pattinson, W. C. Potter, W. A. Prichard, M. B. Spaulding, and C. W. Van Law are among the directors of the Mexican Chamber of Mines, just organized.

James Underhill has received the degree of Ph. D. (Doctor of Philosophy) from the University of Colorado for his work on the geology of Lower Clear Creek Valley, Colorado.

George B. Putnam, formerly with Howard Platt, at Leadville, is now associated with T. H. France, consulting engineer for The United States Mining & Milling Co., with headquarters at Mexico City.

At the celebration of the seventy-fifth anniversary of The Royal Prussian Institute of Technology, Hannover, Germany, one of the most prominent scientific institutions in the world, the honorary degree of doctor of engineering was conferred on Ernst Koerting, the noted European engineer and of the well-known firm of Gebr. Koerting, A. G. Koertingsdorf, Hannover, for his scientific researches and discoveries in gas engines and other important branches of engineering. Dr. Koerting lives in Pegli, Italy. He is interested in a number of large enterprises in the United States, among them the De La Vergne Machine Company, New York, as well as the Schutte-Koerting Company, Philadelphia, and is at present sojourning in this country.

Obituary.

George E. Otis of Redlands, Cal., a well-known jurist and mine owner in southern California and Nevada, died at his home on June 6, after an illness of several weeks. His principal mining interest was in the Cyrus Noble mine at Searchlight, Nevada.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 10 Bacon Block, Oakland, has official reports of the following United States patents issued to Pacific Coast inventors:

822,242.—**Horse Collar Attachment.**—S. Boyer, Colfax, Wash.

822,580.—**Kiln.**—W. A. Butler, San Francisco, Cal.

822,429.—**Electric Street Indicator.**—A. J. Clark, Seattle, Wash.

822,650.—**Oil-burner.**—C. C. Cleveland, Kern, Cal.

822,825.—**Shoe Polisher.**—L. L. Clippinger, Pitchuck, Wash.

822,584.—**Bookkeeping Machine.**—M. M. Cohn, San Francisco, Cal.

822,515.—**Ore Separator.**—F. B. Finley, Los Angeles, Cal.

822,517.—**Winding Roll for Paper.**—W. B. Fleming, South Pasadena, Cal.

822,839.—**Stump and Root Remover.**—M. A. Fry, Seattle, Wash.

822,601.—**Tumbler for Bucket Elevators.**—J. H. Gray, San Francisco, Cal.

822,363 & 822,364.—**Device for Preventing Deceptive Refilling of Bottles.**—L. F. Hammer, Stockton, Cal.

822,739.—**Protective Bottle.**—J. C. Henderson, Los Angeles, Cal.

822,368.—**Gate.**—E. M. Hoagland, San Francisco, Cal.

822,457.—**Lamp Extinguisher.**—G. Kerr, Dallas, Ore.

822,378.—**Rotary Engine.**—A. S. Levake, Seattle, Wash.

822,530.—**Coupling for Glass Tubes.**—L. P. Lowe, San Francisco, Cal.

822,531.—**Manufacturing Gas.**—L. P. Lowe, San Francisco, Cal.

822,379.—**Sand-Blast Apparatus.**—H. Luckenbach, San Francisco, Cal.

822,619.—**Cool Brooder.**—N. A. Lybeck, Corning, Cal.

822,381.—**Shoe.**—R. Moos, Placerville, Cal.

822,547.—**Excavator.**—G. W. Nicolson, Mojave, Cal.

822,398.—**Ore Apparatus.**—A. Soderling, Bodie, Cal.

EDITORIAL.

AMONG THE unpleasant incidents calling for comment, in connection with the San Francisco disaster, is the action of the Western Union Telegraph Company. The Grand Jury has made a scathing report and the president of the Company has published his reply, in which he fails to meet the charges preferred. At Berkeley the Western Union office did refuse messages, but it collected ten cents for those delivered—as the Postal Telegraph did not—and we know of many messages that were sent from the East, and paid for, that never were delivered. Furthermore, in other cases telegrams were delivered—for instance, from Los Angeles—several days after the sender arrived at the address on the telegram. Whether the denunciations of the Grand Jury are fully justified, we do not know; but we do know that the Western Union behaved so badly that it is to be regretted no fitting punishment is practicable. People are too busy to take steps to recover fifty cents or a dollar, and in any event the money involved is nothing as compared to the wrong done, alike to the individual and to the community.

ON ANOTHER PAGE we publish an excerpt from the geological report of an acknowledged authority in which the new term 'blout' is advocated and adopted. 'Blout' is to be the technical pseudomorph of 'blow out,' a term often used by miners and expressive of those large, rather shapeless, outcrops of quartz that have not sufficient length or direction to come under the designation of 'vein' or 'lode.' Blout has advantages; it should commend itself to our English friends who love compression; it reminds us of the man whose name was Sevenoaks and called himself Snooks, for short. It is first cousin to the names pronounced Marchbanks, Punsby, Sinjen, Cohoon, which are related to Marjoribanks, Ponsonby, St. John and Colquhoun, respectively, just as 'blout' is to 'blow out.' We doubt whether blout has come to stay; we hope not.

THE HEAVIEST STAMP-MILL in operation anywhere is the consolidated plant of the Simmer East and Knights Deep mines at Johannesburg. When completed it will contain 450 stamps as compared to the 540 heads of the Alaska-Treadwell. But the South African mill is equipped with unusually heavy stamps. Each one weighs 1,550 pounds and has a crushing capacity of eight tons per head; 200 stamps and two tube-mills are already at work. The big stamp-duty is due to the heavy weight of the stamps and it is not prejudicial to extraction because the oversize pulp undergoes re-grinding in tube-mills. We expect to see further additions to the re-grinding apparatus, which appears to be scant. As it is, the consolidated mill will be equal in crushing capacity to 600 ordinary Californian stamps and it will treat about one million tons per annum.

OF THE 870,000,000 pounds of copper produced by the United States last year, the mines of the Amalgamated Company yielded 216,000,000 or about 25 per cent. While the production of the entire country has increased 45 per cent since 1899, when the Amalgamated was organized, the mines of the latter have shown no commensurate increase until this year. The discoveries at the deep levels of the Anaconda and the continued productiveness of the Boston & Montana Company's mines are accountable for the improved position, as exhibited in the recent annual report. But that annual report gives little information of any value except the statistics of production, and the reports of the subsidiary companies do not help, simply because the shareholders do not know what is the holding of the Amalgamated in each case. The Amalgamated remains our standard specimen of a blind pool offering giddy chances for a gamble, but no inducement to a careful investor.

THE SCARCITY OF TIN and the probability of short supplies have caused extraordinary speculation in that metal. In 1896 the price at London was only £56, last year it reached £166 and this year, on May 14, it jumped to the wholly unprecedented figure of £215 per ton. In 1896 the visible supply was estimated at 33,073 tons and this year it has been down to 12,300 tons. The price is largely dominated by conditions in the Malay peninsula where increased cost of production and export taxes have been detrimental factors. No new sources of supply appear forthcoming. In Banka and Billiton there is a slight increase of sales. Bolivia is the only country where tin mining is undergoing healthy development, though the yield of 13,188 tons during 1905 was only 696 tons better than the year before. Meanwhile consumption is enormous and increasing. If present conditions continue, the result will be to stimulate the invention of a substitute, for high prices and uncertain supplies will surely kill the industrial uses of the metal.

NOT LONG AGO we referred to the myths that cling to that survival of discarded theories—the true fissure vein, and we suggested that instead of new definitions of a misleading term, it would be better to discard it for good. This week we are in receipt of a circular, issued by a New York promoter, in which the following statement appears: "As to the probabilities of the mines being of sufficient depth to continue profitable for many years, while there is no method known of determining this question, many men of the widest experience place confidence in the belief that the depth of pay-ore in a true fissure vein is as great as its length on the surface. The geologists, J. E. Spurr and W. Lindgren, who have been of valuable service to the Government in the researches of the United States Geological Survey, agree in stating that this belief is evidently supported by sound principle, although science has not yet discovered the cause of this phenomenon." No, the gentlemen referred to are too busy to ascertain the cause of a 'phenomenon' that does not exist or to refute an assertion which is without warrant. So we venture to do it for them. Such pseudo-science does much harm. It would be more profitable to investigate the phenomenon, presented with weary iteration, of irresponsible schemers who masquerade as experienced miners.

AUSTRALIA is prospering. Better seasons and higher metal prices have proved stimulating to agriculture and to mining respectively. At Broken Hill, the greatest silver mining region of the present day, there is much interest in the beneficiation of the zinc, both in the ore and in the vast dumps of the big mines. There has been scant progress in coarse concentration at Broken Hill during recent years; it is true the Hancock and the May jigs have been employed successfully, but the metallurgical tendency is all toward finer crushing. Krupp ball-mills of the No. 8 size have been replaced by No. 5. At the South mine, experiments with the grinding pan, as used at the Ivanhoe mine, in Western Australia, have given good results. Taking all the middling from one jig and grinding to 100-mesh, the recovery

has been increased 5 to 7.5 per cent. The manager, Mr. William E. Wainwright, expects that with pans his cost will be from 10 to 12 pence as compared to 18 pence, the cost with ball-mills. But now comes the tube-mill; for it is to be tried, there being a hope that the hard and barren rhodonite in the ore will serve to grind the softer metalliferous portion. The Wilfley table is reported to be most efficient, although the new Krupp table gives a better extraction at the expense of capacity, requiring also 350 strokes to 250 of the Wilfley.

Several large concentrators are under construction at Broken Hill. The South mine will have one of a 1,000-ton daily capacity; another of similar size is being erected for the Sulphide Corporation. A 350-ton plant at the South Blocks mine will be running in September. The Zinc Corporation has commenced the erection of a concentrator with 2,000 tons daily capacity to treat tailing and the experimental plant of this company, at the British Broken Hill Proprietary mine, is to be doubled, so as to handle 400 tons daily.

Several new processes are being put to the test. The plant erected by the De Bavay Company to treat tailing at the North mine, has been hindered in starting, but it is claimed that an extraction of 85 to 88 per cent of the zinc is assured, making a concentrate carrying 46 to 48 per cent, containing half of the silver and but little lead. The Cattermole or Ballot process is doing good work at the Central mine, the recovery being 80 per cent of the zinc and 75 per cent of both the lead and silver, so that a rich concentrate is secured. All this work will mean an important addition to the production of zinc and it is interesting to professional men as indicating another conquest in the field of complex ores.

THE MICHIGAN COLLEGE OF MINES is required by law to maintain a collection of the minerals occurring in the State and such a collection has been in course of preparation for several years. In order to render it of maximum usefulness, Mr. F. W. McNair, the president of the College, has originated a plan for lending a number of subordinate sets of specimens to such high schools of the State as give instruction in geology and its allied subjects. As the official circular says: "The object is partly economic. Obviously, the more the people in general are interested in the mineral resources of the State, and the greater the knowledge of these possessed by them, the more likely are such resources to be developed, and the greater will be the benefit to the State at large. Partly, the object is educational. In the same way that botany may contribute to the pleasure of one possessing even a slight knowledge of the plants of his vicinity, in the same way that this knowledge may add to his breadth and culture, so the knowledge of the rocks and minerals may be a powerful influence toward these ends, and may, no less than any other form of nature study, contribute toward good citizenship. The fact that nature study impresses the rule of law in the universe, is nowhere more forcibly illustrated than in the study of the crystal form of minerals, and nowhere in nature are organization and growth more clearly exemplified than in the rocks and minerals which compose the earth." The sentiment is worthy of the deed. We congratulate our friends at Houghton and more especially Mr. A. E. Seaman, professor of geology in the College of Mines, to whose enthusiastic interest in the plan and personal familiarity with the details of Michigan's resources, is credited the representative character of the collection.

The Office of State Mineralogist.

The State Mining Bureau is still without a properly appointed chief. Mr. Lewis E. Aubury is holding office without re-appointment and in daily expectation of being introduced to his successor; this condition has lasted well over a year and it is neither fair to him nor to the important office he fills. Such is the result of mixing politics with technology. When the new Trustees of the Bureau were appointed last November, the mining community had reason to hope for an excellent administration, for the men selected were representative and particularly capable of giving good service. But their efforts have been of slight avail. They found very soon that their hands were tied, even the selection of their own secretary being made without consulting them. Meanwhile it is generally known that the Trustees have selected a geologist for the office of State Mineralogist and that his name is George D. Louderback, at present professor in the University of Nevada. But the Governor, however earnest a man he may be, lacks decision; he has failed to make up his mind, as if it were necessary for him to do more than confirm a nomination made by the Trustees he himself appointed and one of whose chief duties it is to make this very selection. It is a matter of regret that the Mining Bureau should continue to suffer in its work for want of a properly accredited head; if Mr. Pardee cannot come to a decision, why not do justice to Mr. Aubury and confirm him for the remainder of the term, half of which is nearly gone?

On the other hand, we venture to refer to the selection of Mr. Louderback, in order to mention certain criticisms already made in anticipation of his appointment. It is said that he is the nominee of the geological department of the University of California, from which he graduated. Some people want a practical mining engineer to fill the post, but surely the day is gone by when an academic training is held to unfit a man for holding a State office and it seems proper enough that a geologist possessing some executive ability should be selected. As to the connection with the State University, it is most unlikely that there will be any attempt to annex the Bureau, for this would be suicidal. Both institutions are supported from the funds of the State and to use one in the interest of the other would simply invite a less appropriation at the next meeting of the Legislature. We are also informed on trustworthy authority that the Governor has delayed action because he wants "a bigger man" for the office and that it was declined both by Charles G. Yale and Ross E. Browne. Even Waldemar Lindgren's name was mentioned, as if he would resign from the United States Geological Survey to take a precarious office under the State. The Governor is a professional man when out of office and he ought to know that men of established reputation are not willing to accept a position which places them within the tangled wires of politics, and that no so-called big man—that is to say, an engineer or geologist of wide experience—will accept a post which Mr. Pardee himself is rendering absurd by his vagaries. This has been the trouble from time immemorial with such State appointments; to get a good man and to keep him, you must pay him a reasonable livelihood and he must be assured of his position long enough to perfect his organization and to bring his work to fruition. California needs a first-rate State Mineralogist—at a proper salary—a well organized Bureau, and a group of trustees just about of the sort now in office, and then a Governor who will be content to let well enough alone. And this we say without danger of any imputation of our motives in saying it.

By the Way.

In a recent issue 'The Evening Post,' of New York, says some good things about the revulsion of sentiment against certain forms of wealth.

How quickly the revulsion has come about may be gathered from the fact that it is only four years since the feast given by our 'captains of industry' was widely said to be the most impressive spectacle that America could show to Prince Henry of Prussia. Today many of these captains are variously under investigation or suspected, universities are rebuked for receiving their money, warrant-servers seek their persons, their hegemony has sunk to that of a world of graft. A 'social philosopher' declares in the 'North American Review' the inexpediency of any American citizen being permitted to earn more than the salary of the President of the nation. In short, great wealth is now on the defensive, its possession requires explanation if not apology. The virtuous scion of ten generations of clergymen or bank clerks may now turn up his nose and thank Heaven that there never was a captain of industry in his family.

Possibly the moral indignation of the have-nots against the haves is excessive. The well-to-do, and even the poor, frequently enjoy their privileged condition through no merit of their own. The salaried man who is inclined to rejoice inordinately in his superior lot should recall that only accident may have kept the golden bar sinister off his escutcheon—but for the grace of God he might be personally even as the Armours and Rockefellers. In fact, we counsel such a person not readily to give place unto wrath, but to fix his attention rather upon the blessedness of his own condition. Better be a serene retail hatter than a fevered excoriator of the Trusts. The Horatian mood retains its value, and we can imagine an entire generation of folk neither poor nor rich murmuring, "Beatus ille qui procul negotiis," with a new relish.

Certainly, the delights of the middling lot have received fresh illustration from the recent embarrassments of the unco' rich. The obscure citizen may put his Sunday quarter in the plate without fearing the echo, "Tainted money." He is not subject to the importunity of those who would force free stock upon him, but may select and buy such securities as his judgment approves; he is not liable to the harrassing debate whether his Trust should be fined or his person imprisoned; even his passions and weaknesses are safeguarded by the withholding of his annual insurance dividends, while no such fence against temptation surrounds mere insurance presidents. Finally, the average prudent man may bargain for his services without being enjoined for restraint of trade; he may accumulate "green trading stamps" without falling under the law against receiving rebates; he may kill and even can his own chicken without dread of theorists, chemists, or sociologists. To contrast with this carefree lot that of the millionaire subject, as it is, to all manner of suspicion and constraint, is superfluous.

A further and rarer felicity awaits the man who adroitly steers between poverty and riches. He may fairly aspire to association with gentlefolk—with the unheeded mass among which good manners and the older social amenities have taken refuge. What one may call the gentler pleasures of life are largely forbidden to the energetic persons who manage colossal deals of mornings and symbolically huge motors and steam-yachts afternoons and Sundays. Under modern conditions of business success, it is possible, perhaps, but most difficult, to practise the finest of all arts—that of living. We opine that these considerations should turn wrath against the financial generation now in the pillory into something like compassion. What a positive good fortune it should seem to work in a calling where ruthlessness is not the condition of success, and where the over-accumulation of money is not the goal.

To-day a wise father might well say: "Son, from generation to generation this family has earned its living and paid its bills, it has had the privilege of honest and gentle associations, no member has condescended to be very rich, none has been indecently poor, it is for you to be worthy of this tradition—to keep your family in reasonable comfort and yourself out of the committees, courts, and newspapers." That this would be good advice cannot readily be gainsaid; that it will be universally given may be doubted. Sufficient volunteers will probably be found to undertake the invidious and disadvantageous succession of the present magnates. Many more, we trust and confidently believe, will shake off the cant and cult of mammonism, readjust their standards, and come to a state of mind equally removed from sullen envy of the wealthy lower classes, and from discontent at their own humble but highly favored lot.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

It is not allowed to cut timber, either fallen or standing, on forest reserves without permit.

The United States produces more than half of the world's copper. The production of 1905 was 397,909 tons, out of a total in the world of 700,000 tons.

Where A discovers ore on land adjoining B's patented ground, this discovery does not give A any right to enter B's land to mine ore, or for any other purpose.

Steel corrodes more readily than common bar or sheet iron under similar conditions, probably due to the finely intermingled atoms of carbon present in the steel.

Those who wish to mine on forest reserves, or to cut timber thereon, should make application to the Land Office at Washington for full information and instructions.

"Roughly speaking," says Hixon, "matte is a compound of the sulphides, arsenides, and antimonides of the metals, while slag is a union of the oxides of the metals with the oxide of silicon."

The Caminetti act, relating to hydraulic mining in California, only mentions mining by hydraulic method. Whether the courts would interpret this law as applicable to other methods of mining gravel remains to be determined.

The presence of garnet in a contact zone of mineralization does not signify valuable deposits of copper ore, nor does the garnet detract from the value of the orebody. Garnet occurs in both good and poor copper mines, and abundantly also where there is no copper at all.

A mine owner, company or individual, is responsible for damage done to the property of another on the surface, due to sinking of the ground from caving or settling of mine workings. The claim that the work was done in miner-like and proper manner, will not suffice.

Any person, a citizen of the United States, or one having declared his intention to become such, whether male or female, adult or minor, may locate the unoccupied mineral lands of the United States in accordance with the Federal laws, and by conforming to the laws of the State or district in which the land is situated.

Nickel and cobalt, like chromium, are most abundant in olivine rocks, occurring as accessory ingredients in this rock, as well as in pyrite and pyrrhotite, and in hornblende and biotite to a small extent. The amount of nickel in rocks is seldom more than 0.10 or 0.20%, while that of cobalt is only exceptionally more than a trace.

Most mine and mill buildings, head-frames, and other structures about mines are wood, and therefore require special provisions for protection against fire. In view of this fact, and the heavy loss resulting from fires, both directly and indirectly, steel is being introduced in new construction and is replacing wood in many instances where rebuilding is necessary. Steel head-frames, which ten or twelve years ago were a novelty, and looked upon with disfavor by many mine superintendents, are now generally acknowledged to be superior to wood in every respect, except possibly, first cost.

The lightness of terra-cotta, its great resisting strength, its durability and its indestructibility by frost, water, and fire make it particularly desirable in the construction of large buildings. It is made from fire-brick clay in the form of hollow blocks, formed with webs inside, so as to give extra strength and to keep the work true while drying, and, in no part, more than 1 to 1.5 in. in thickness, except that to bond with brick-work, it must be at least 4 in. thick. When extra strength is needed, the hollow spaces may be filled with concrete or brick-work, which greatly increases its crushing strength. We may place the safe working strength of such blocks, in the wall, at 5 tons per sq. ft. when unfilled, and at 10 tons per sq. ft. when filled solid with brick-work or concrete. The weight of terra-cotta in solid blocks is 122 lb. per cu. ft. When made into hollow blocks, the weight of these blocks varies from 65 to 85 lb. per cu. ft., the smaller pieces being proportionally heavier. For the exterior coating of fire-proof buildings it is now considered as the most suitable material available.

Vanadium, according to the investigations of Hillebrand, predominates in the less silicious igneous rocks and is absent, or nearly so, in those high in silica. It is an ingredient of pyroxene, hornblende and biotite, but not of olivine, and is also found as an ingredient of ilmenite in titaniferous iron ores. Its amount is small, seldom over 0.05 per cent.

The following is the process carried out by the Pittsburgh & Montana Copper Co. at Butte. The matte, which averages 20% copper, is treated in a converter made of steel plates two inches thick, lined with one nine-inch course of magnesite brick; all the silica required in converting is obtained by adding silicious ores into the converter. Matte as low as 8% copper has been successfully converted, and the converter did not require to be re-lined, during the ten weeks it had been in operation.

Where compressed air is available, the small air-hammer drill may prove to be an excellent tool for use in sampling a hard vein. The machine should be provided with a moil-shaped bit, instead of that with the ordinary blunt-chisel bit usually employed in drilling. The success of the use of this device depends largely upon the practical sense of the man manipulating the machine. The air-hammer drill has proved its usefulness in rapidly drilling shallow holes, and there seems no good reason why in competent hands it should not be useful in cutting a channel of uniform depth and width across a vein of hard rock of any description.

A young man with a good public-school education, under competent instruction, should be able to learn to assay ores for gold, silver, copper and lead in from three to six months. Some pupils prove more adept than others. The first work he must perform is the grinding of the sample. The novice is inclined to consider this an unnecessary part of the drudgery of the assay-office, but it is, in fact, a most important portion of the process. One thing the beginner in assaying must learn promptly, and that is not to reject any part of the sample, but to continue grinding and screening until every portion has been reduced to pass the screen selected as suitable for the sample to be assayed.

Slow-burning or mill construction was introduced originally for cotton mills. Its motive is to reduce the fire-risk to the lowest point without going to the expense of fire-proof construction. It consists in disposing the timber and plank in heavy solid masses so as to expose the least number of ignitible corners or projections, and so that such corners may be easily reached by hose in case of fire. The floors are reached by stairways and elevators placed in a separate brick shaft, the communicating openings of each floor being closed by fire-proofed doors. Thus there is little chance of fire rising from floor to floor. The ceiling situated over inflammable materials or processes, is protected by plaster laid on wire-lath or expanded metal, this plastering following the lines of the ceiling so as to leave no interspaces.

Alcohol, or alcohol mixed with turpentine, is generally employed in blow-pipe work where gas is not available for a Bunsen burner. Olive oil is also used in blow-pipe work. When about to light an alcohol lamp withdraw the burner and wick sufficiently to permit blowing vigorously into the body of the lamp. This will remove any gas which may have accumulated therein, preventing those small and annoying explosions which otherwise so frequently occur. Any book on the use of the blow-pipe will give the necessary instructions. The flame of a lamp, or candle, is divided into three sections: a very hot, non-luminous outer portion, and a yellow, luminous portion surrounding an inner, darker part, consisting of unburned gases. This inner flame is not always visible. To produce an oxidizing flame insert the blow-pipe tip into the flame about one-third of its diameter, and a short distance above the burner or wick. The blue flame thus created is slightly reducing, but just beyond its tip is a scarcely visible intensely hot oxidizing zone, in which the mineral to be reduced must be held. To produce the reducing flame—which is yellow—place the tip of the blow-pipe a short distance from the lamp flame, and a little above its middle, and blow directly across it, turning the entire flame upon the object to be reduced.

A millman, fond of experimenting, removed the belt from a vanning machine and covered the upper rollers with a board table on which he secured silver-plated copper plates of the usual kind. He passed his mill-pulp over this vibrating table as it came from the apron-plates, and claimed that a highly satisfactory saving was the result. Why more gold was not saved on the apron-plates, he did not state. Small strips of amalgamating plate, placed on the spreader of a concentrating machine will often accumulate gold and amalgam. If the millman would carefully investigate the amount of loss, in milling, and endeavor by careful sampling of the tailing to find out where the loss actually occurs, he may in many cases be able to check the escape of gold by application of the proper remedy. Sometimes it will be found to be due to fine sulphide escaping over the vanner belt, owing to the fact that no classification of the pulp is made before concentrating. And often, it will be learned, that the loss is in the coarser sand, particles of which still inclose gold. Finer grinding is the only remedy for this condition, and the gold content of the sand may not justify the additional expense.

Stadia surveying gives only approximate measurements at best, the closest results being obtained on level ground. Where the topography is rough, errors are almost certain to occur, for, if the rodman holds the rod in vertical position absolute accuracy is impossible, though by calculating the angle of elevation (or by use of stadia tables), the distance can be closely approximated; if the rod be held normal to the angle of elevation or depression of the telescope of the instrument, the foot of the rod will not be vertically below the point on the rod intersected by the cross-hairs. This discrepancy may also be corrected by use of plummet in the hands of the rodman, but even then, great accuracy is unobtainable. Stadia surveying, if carefully done, will be very close to work done accurately by other methods, and over rough ground it is as good as ordinary surveying where particular pains are not taken, but if absolute accuracy is necessary, other means than the stadia must be employed. When about to do stadia work, the adjustment of the wires should be inquired into and if not correct, the necessary correction should be made. If the stations are more than 600 ft. apart the likelihood of error is increased.

The hardening of steel is due to suddenly arresting the progress of a change which otherwise takes place in the condition of the steel when slowly passing from a higher to a lower temperature. The metal having been completely and suddenly cooled, no further change can take place. This is accomplished by plunging the red hot steel into water. In the case of a pick, the steel point is burnished by the blacksmith—generally by rubbing on a board covered with sand. This brightens the surface of the steel. The shank of the pick still retains a high heat, sufficient to carry it down to the point. Watching it closely, a beautiful dark blue color is seen. Just at the moment this reaches the end of the pick-point, it should be given the final plunge, and the point will retain this color, dark blue, which is the best for hard rock, as well as that which is softer. Drills may be tempered in much the same way. Usually drills are heated and forged and then thrown down to cool, being afterward reheated, plunged and tempered by allowing the color to run down to the bit, but drills for hard rock should be tempered from straw to light bronze color, blue being too soft. In heating to forge or to temper, care must be taken not to over-heat the metal, as this burns out the carbon and ruins the steel for any use, and the burned end must be cut off and thrown away, causing a loss of fuel, time and material. Some blacksmiths temper rock-drills in the following manner: First, heat the bit till cherry-red, then plunge into water for a moment, till partly cooled, when it is rubbed on a stone or sanded board to remove the scales of iron oxide so that the play of colors can be seen in a dark corner of the shop. At between 430° F. and 600° F. these vary from a very pale yellow, through straw, to brown, purple and full blue to dark blue. If the cooling is uniform the colors should advance parallel to the cutting edge, otherwise that side of the bit on which the colors are moving most rapidly should be held in water a moment. When the colors move parallel with the edge (this is important to insure uniform hardness), watch until it is a straw color and quickly plunge into the water a short distance, moving it about until the steam ceases to form, when it may be left in a quenching bath, usually water, but often brine, tallow, or coal tar, which are said to vary the rate of cooling in the order given.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

WHEN CAN MINING GROUND BE CONSIDERED THOROUGHLY PROSPECTED?

The Editor:

Sir—The prevalent idea in mining is that when a block of ground has been exposed on all four sides, it is thoroughly developed. But is this always the case? In ordinary veins of medium grade ore, where the average runs rather evenly, as in those of South Africa, the rule may be safely followed; but in pockety lodes, or veins that are much faulted and altered, it may be well to consider the exception.

If all the data available could be brought together, I believe it would be found that the exception is much more common, for worse as well as for better, than is generally supposed. I recall a number of instances of ground being abandoned as thoroughly prospected, where it was found, later, that a few feet more of work would have reached the desired pay-ore. I judge that all mining men can recall some such experience; but I believe the one that affords the basis for this article is unique, and it is a personal experience.

A section of the mine worked had, supposedly, been thoroughly prospected, and all ore that paid expenses, and quite a lot that did not, had been stoped out; this part of the mine was therefore abandoned, two years before the mine was finally shut down and sold for a nominal sum. Several pillars were left in this ground, but on no side did assays show milling ore, and it was sampled every meter.

In the particular pillar I have referred to, FDE (see Fig. 2), was the main working level, and the ground had been stoped out above this level. When the time came for prospecting the ground below, a winze was started at F, the most likely spot; and this was sunk 25 ft. At this depth the vein was faulted, as shown in Fig. 3. A cross-cut was run from the foot of the winze, 30 ft. into the hanging-wall rock, and the vein cut again, at this distance. From this last point a winze 25 ft. deep was sunk on the vein to A (see Fig. 2). These two winzes were sampled every meter, nowhere showing pay-ore; most of the ore being practically barren.

The vein was about three feet wide. At A (see Fig. 2), a drift was run each way; to the north, but a short distance; but to the south, it was run 60 ft.; the ore, throughout, being very low-grade. At 60 ft. a raise was run 20 ft. and the drift continued on this level 40 ft.; connecting with stope Z. Here we had a pillar stoped to the limit of pay values on two sides, and developed on the other two sides by winze and drift. Following the rule, the block being small, it was left intact, as valueless.

Two years later, as stated, the property was sold. The purchasers, working on a smaller scale, milled the filling and old dumps, mostly at a loss. Nearly two years later still, when they were $130,000 "in the hole," they opened up again that part of the mine now under discussion, in hopes of finding filling or ore that would pay. In sampling the ground at C (see Fig. 2) a sample was taken of some rock that had fallen from the roof, and as this assayed about $10 per ton, they started to stope, the ore improving as they went up. Within 12 ft. they had five feet of very rich ore.

The result was, that they took out nearly $300,000 gold, within 40 days, from a pocket lying as shown in Fig. 2. Nowhere was it over 23 ft. wide by 55 ft. long, by the width of the vein, three to five feet. The remainder of the ground turned out about as shown in Fig. 2. The faulted end was raised to the level of the drift FDE, and about 40 ft. over. No ore of value was found in the fragment between FDE and the fault PP' (see Fig. 3); all the richness being bunched (with a vengeance) in the other fragment P'C.

Noting the above, the question arises: Does development on four sides prove the value of a block of ground? And this leads to another: When should a mine be abandoned? These are vital questions that often force themselves upon us, and leave their answer to our co-workers, or to the peers in the profession, whose ability and larger experience may have caused them to come to some conclusion in regard to the matter. For myself, I am almost inclined to follow the Irishman's advice: "Always drive 10 ft. beyond where you stop." In stoping, this would mean, knock it all down.

LODE-MINING IN ALASKA.

The Editor:

Sir—I noticed in your issue of May 12 an article on this subject, written by Mr. Chester W. Purington, which in my judgment does not do justice to that Territory. I have been frequently charged with pessimism myself, but the pessimistic tone of Mr. Purington's article was so pronounced, and the descriptions so general that I am prompted to take up the cudgels in behalf of Alaska, in so far as lode-mining is concerned.

While I must agree with Mr. Purington in many of his statements, yet it strikes me that he has not made due allowance for the unfavorable conditions which exist in Alaska, many of which are not found in any other mining region in the States. For instance, although much of the coast-line can be prospected from boats, it is due to the average prospector to recognize the fact that a man coming from the interior is badly equipped to manage small boats on the Alaskan waters, where the tides, currents and winds create conditions such as even thoroughly experienced sailors often fail to contend against with success. Consequently, before any prospector should think of following his calling in Alaska, it is requisite that he be a fairly good sailor himself, or else be accompanied by one.

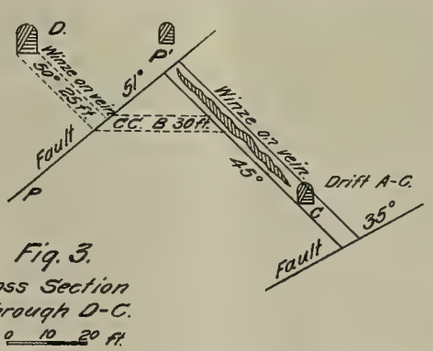

Fig. 3. Cross Section through D-C.

Another difficulty the prospector has to overcome is the heavy growth of underbrush including sallal, devil's clubs, manzanita bushes, to say nothing of the fallen timber which often is so thick on the ground that a man is kept continually climbing over it, rendering it impossible for him to travel more than half or three-quarters of a mile in an hour. Then again every prospector has to pack on his own back his supplies, bedding, etc., whenever he leaves his boat to penetrate into the wilderness. Finally, natural rock-exposures are scarce, except at high levels. Even in the creek-beds it is a rare occurrence to find rock in place exposed; consequently every prospector has a great deal of difficulty in finding veins, even after he has found float.

As it is my desire to make this communication as brief as possible, I will drop the subject of unfavorable factors right here and go on to a discussion of the actual conditions as they exist today with regard to the development work at present being carried on. Mr. Purington gives due consideration to the operations at the Alaska Treadwell Co. in Juneau district, but does not mention the fact that the Jualin mine was being operated during last season and that a new orebody had been discovered which yielded about $20 per ton by amalgamation, together with about one per cent of concentrate, carrying $150 per ton. This orebody is known to be 350 ft. long and 5 ft. wide near its apex, which is about 100 ft. below the surface. The drift from which the ore was taken last season had been driven within about 30 ft. of the apex and during the past winter sinking has been done in order to properly develop this orebody.

Neither does he mention the Eagle River mines, on the coast, about 30 miles from Juneau, which have been successfully operated now for the past two years and promise to yield valuable, even if not extensive, orebodies. However, the high grade of the ore, the persistency of the shoot, the accessibility of the mine, and free-milling character of the quartz warrant the assertion that this property is the peer of many successful mines in other portions of the United States. The Alaska Perseverance property in Silver Bow basin, about four miles from Juneau, is being operated continuously, and although no ore is being milled at present a 100-stamp mill is being erected, and the development so far done warrants the assertion that within a reasonable time, the product from this mine will be of sufficient importance to place it among the big properties of the States. This is another that Mr. Purington fails to mention. Of course the properties on Berner's bay, known as the Nowell mines, which have been in the hands of a receiver for several years, can hardly be taken into consideration at this time, but should certain negotiations which are now pending be carried through, it will not be long before this will be added to the producing mines in the Juneau district.

When the other portions of the Alaskan coast are considered it is quite true that up to the present time there may be said to be only two districts which give promise of becoming of any importance. These are Prince of Wales island and Prince William sound, with the islands adjacent. While Mr. Purington is correct in stating that both these districts have failed, so far, to make any appreciable production, yet it is a fact that while on Prince of Wales island in March 1905 there were only about 50 tons of ore being mined per day. During the visit I made in April 1906 I found this product had been increased to about 400 tons of copper-bearing ore per day and the number of properties on which serious development work was being performed had been increased from two, which was the total in March 1905, to eight, as follows: The Stevenstown, owned by the Hadley Consolidated Mining Co.; the Mamie, operated by the Brown Alaska Co.; the Mt. Andrews, by the Britannia Smelting Co.; the Rush & Brown, operated by the Alaska Copper Co.; the Khyam, by the Omar Mining Co.; the Niblack, by the Niblack Copper Co.; the Jumbo group, by the Sulzer Industrial Co.; and the Copper Mount, by the Alaska Copper Co. In addition to these properties, there are several locations on which development work is being done in

earnest and many of these promise to be shipping propositions within the next year or two.

In the Prince William Sound district there are only the Beatson property, on Latouche island, and the Gladaugh mine at Ellamar, which have made any regular shipments, although sample shipments have been made from a property on Landlock bay, also from a claim situated on the east side of Latouche island. During the present season serious attempts at development are being carried on by the Reynolds Alaska Development Co. on properties on Boulder bay, also on Latouche island; the Girwood Syndicate is developing another property on Latouche island which is held under bond; James Buzard and the Hemphell Syndicate are developing properties which are considered to be extensions of the zone on which the Beatson property is situated. In addition to these there are a number of prospectors who are regularly performing assessment work on mineral claims situated on Galena bay, Landlock bay, Boulder bay, Fidalgo bay and other points along the coast-line of Prince William sound, as well as some of the adjacent islands.

When the fact is taken into consideration that until after the Klondike excitement in 1898 no prospecting had been done along the Alaskan coast for veins except in the Juneau district, and the difficulties to which I have referred are considered, together with the fact that it has been almost impossible to obtain capital in any considerable amount to work properties along the coast, I am of the opinion that the progress has been fairly good and although it will not compare with the rapid growth in Colorado, yet when the conditions at present prevalent in Alaska are compared with the conditions as they were during the early history of most any of the western mining States and Territories, I think it may be said that Alaska has not been so remarkably slow.

If Mr. Purington's conclusions as to the poor future for lode-mining in Alaska are based on the geological conditions, then all I can say is that with the exception of British Columbia, the geological conditions with regard to the occurrence of copper, are unique, in fact I do not know of any other mining region where parallel conditions prevail. Development work alone will prove whether the lode mines of Alaska are destined to be of any consequence.

WM. M. BREWER.

Vancouver, June 9, 1906.

THE TREATMENT OF DESERT ORES.

The Editor:

Sir—I have read Mr. Bosqui's article in your issue of May 26, in reply to one of mine in your issue of April 28, and crave space to rectify a few points.

The term 'desert ore' was not used by me as a term of classification of ore; it meant simply ore found in desert regions, and referred particularly to the conditions of treatment there. I did not refer specially to Mr. Bosqui's installation of the Combination mill or to the ore of any particular district, but referred generally to the treatment of soft oxidized ores. Mr. Bosqui's description of the Combination ore, as one in which the oxidized portion is much harder than the sulphide ore, shows it to be an unusual occurrence.

"The latest and best practice in cyaniding" quoted by Mr. Bosqui, would be more correctly termed the "last fashion in cyaniding in South Africa." It is notorious that what was called "double treatment" was boomed some years ago in South Africa, and in consequence a number of double-treatment plants were installed in this and other countries; and they were failures. More recently, the South African practice was to divide the pulp into 'sand' and 'slime' to be separately treated, and this appears to be the ideal treatment for "every modern mill operating on a logical basis," according to Mr. Bosqui. The most recent practice, however, at Johannesburg, is to fine-grind and filter-press the whole pulp, and thus get "one product in one operation," the advantages of which are most clearly and interestingly shown in the abstract of Messrs. Denny's article given in your issue of June 2.

I shall not take up space by replying to Mr. Bosqui's statements on ore treatment seriatim, but I must traverse one statement regarding "the impossibility (from an economic standpoint) of reducing ore to a sufficient fineness to ensure the best recovery" by referring to the fine-grinding of cement-clinker, which is done on an enormous scale and at a low cost.

It appears to me that the "best practice" is to be able to interpret laboratory results on any ore, so as to install the kind of plant economically best suited to its treatment, without reference to what may be the practice in South African or other fields, otherwise than to take advantage of new discoveries in grinding machines, etc. In the case of porous oxidized surface ore it appears to me that the best practice would be to crush dry to a fairly coarse mesh and leach direct in vats, the residue being subsequently passed over amalgamating plates or concentrators, if found to pay. In the case of ore which requires fine-grinding to release the metals, I would fine-grind either dry or with cyanide solution, agitate and filter-press the whole pulp, thus getting "one production in one operation." The point on which I wished to lay most stress was that when cyanide is used at all, it is more logical to treat with cyanide first and amalgamate (when necessary) afterward, than to follow the ordinary procedure.

Finally, I wish to deprecate most strongly the introduction of the personal element, as so patently shown by Mr. Bosqui. I take it, these discussions should be purely impersonal and for the advancement of the art of metallurgy and the interest and instruction of your readers, but not for the ventilation of any personal feeling between professional men.

BERTRAM HUNT.

San Francisco, June 9, 1906.

PROTECTING WATER-PIPES.

The Editor:

Sir—In response to a query appearing in your issue of May 26 in regard to protecting water-pipes in a cold climate, I have found that good results have been attained by burying pipes and disregarding the circumstance of maintaining a uniform grade to attempt draining at one point. It is not a difficult matter to use couplings in depressions and to disconnect them at these lowest points at the beginning of cold weather. I have seen pipes drained (where no convenient couplings permitting the above practice were used) by simply starting a leak by drilling a hole or otherwise. Where moderate pressures, say, to 150 lb. per sq. in., are carried, this seemingly primitive method works well; but where heavy pressure is withstood, the better practice is to use an easily disconnected bolted coupling. When pipe must be kept above ground, a good method is to cover it with a box of square section and of such dimensions as will permit a filling (between the pipe and its boxing) of several inches. This filling, of sawdust, straw, or other similar non-conducting material, will furnish an efficient and cheap protection against low temperatures.

Earth is a most efficient non-conductor, therefore the practice generally in vogue in cold climates includes the burial of pipe-lines. Not only is protection against freezing afforded (if pipe-lines are kept full all winter) but another valuable result is secured, namely, the pipe is held firmly, no movement being permitted even on steep slopes.

Berkeley, June 14, 1906.

A TRUE STORY.

The Editor:

Sir—This is a little history of an occurrence in connection with an immensely rich mining company in central Mexico, which would make much more interesting reading to the mining fraternity if names could be used.

Sancho was a little man, a keen eyed little man, and being a Mexican, he had Mexican ideas of 'mine and thine.' One of them was to get ahead of the English mining company that had come in upon his land. When the company required a part of his farm for a tailing pond, Sancho suddenly developed great business ability, and for land that had hitherto been worth about thirty-seven cents an acre, he wrung out of the corporation the sum of five thousand dollars. His Mexican neighbors were all elated over this success, and Sancho was forced by the laws of Mexican propriety to give an ox-roast or barbecue in celebration. As time went by Sancho settled comfortably down to a life of ease, although he still continued to work his shift in the cyanide-plant. He knew the value contained in the hundreds of tons of tailing and solution that were thrown out daily. These had been accumulating on the land which he had sold to the company and the solution had been seeping through them, forming a small rivulet which ran through the canyon traversing his remaining acres of rocks and brush, dealing death and destruction to the animals that drank of it. Quite frequently Sancho lost a cow, a burro, or a horse and the company grudgingly paid for them their full market-value. Finally Sancho suggested that with their permission he would box in the stream and carry it entirely across his land if they would save him from damage-suits which might be brought by his neighbor next below. Permission was given him and Sancho lost no time in carrying out his plan. There was continuous travel over Sancho's new launder but no one suspected what he had so carefully concealed at one place in the launder; he dreamed on in his quiet way, and continued to build up his fortune. The stars might have told a tale but they blinked merrily at the joke and shed no light upon the subject. When all was quiet save for the roar of the mills, Sancho stole under the cover of darkness to his zinc-box which he had most craftily concealed in the shady part of the canyon. Listening carefully for any footfalls he would slip the cover off the zinc-box and proceed to clean up. These clean-ups would often amount to 500 pesos in less than two weeks. And so he continued for about two years, until he became so bold as to ship his bullion by express instead of selling it at a heavy discount, as he had hitherto done. The shipment was of course reported by the express agent to the general manager of the company, who lost no time in investigating its source and then in installing boxes of his own. Although a very considerable amount of bullion was secured to add to the monthly clean-up of the big plants, strangely enough it was not itemized nor was it mentioned in the report to the London stockholders.

While Sancho was being interrogated regarding the quantity of bullion he had already secured, he stoutly maintained that this clean-up was only the third he had made. Realizing that he was not liable to arrest, and that the officers of the company were not anxious to have the matter made public, he took heart and at the same time took the manager into his confidence and exhibited his bank-book with much pride, pointing out with care and voluble explanation the monthly entries totaling five figures.

GAMBUCINO.

Mazatlan, June 9, 1906.

A DISCLAIMER.

The Editor:

Sir—My attention has lately been called to a circular issued by The Mitchell Mining Co. of Arizona, in which I am quoted as endorsing the property at La Dicha, State of Guerrero, Mexico, to the extent of some 8,000,000 tons of ore having a value of some $57,000,000. I wish to deny absolutely ever having made such a statement by letter or verbally. My examination of the property in January, 1905, showed 1,800,000 tons of ore that can only be smelted, averaging 1.86% copper, traces of gold and silver.

Trusting you will find space in your esteemed publication for this statement, I am, etc.

T. H. FRANCE.

Mexico, D. F., June 1, 1906.

Two parts of aluminum and one part of zinc form an alloy to which has been given the name 'alzene.' It is equal in strength to good cast iron and superior to it in the matter of elastic limit. It takes a fine, smooth finish and does not readily oxidize. The color is silver white. It melts at a low red heat and is very fluid, running freely to the extremities of the mold and filling small or thin parts. Great care must be exercised in melting it, particularly when mixing the two metals, in order to preserve its smooth working qualities. It is somewhat brittle and hence unsuited to such pieces as require the toughness possessed by brass. The tensile strength is approximately 22,000 lb. per sq. in. and 3.3 is the specific gravity.—From 'Engineering News.'

A Great Gem Mine.—The sapphire workings at Yogo gulch, Montana, are being gradually developed into a great and permanent industry. The Yogo dike is perhaps the greatest gem mine in the world. It is four miles long. It is estimated that the workable sapphire-bearing rock would approximate 10,000,000 cubic yards. A mining plant is being erected there which will quadruple the previous output and make Montana sapphire mining an important factor in American gem production.

The stones are not of large size. They range from 'culls,' used for watch jewels and other mechanical purposes, to gems averaging, when cut, from half a carat to 2 or 3 carats and rarely up to 5 or 6. As gems they are brilliant, free from flaws and of good color, ranging from light shades to the rich, deep blue of oriental sapphires. The Yogo crystals have an advantage for mechanical uses over East India stones in their form, which is largely short prismatic or rhombohedral with flat basal terminations, and hence they need much less cutting for such purposes as watch jewels. The gems are sent to Amsterdam for cutting, and yield from two-fifths to one-half that weight of finished stones.

The Milling of Gold Ores in California.

Written for the MINING AND SCIENTIFIC PRESS by
W. H. STORMS.

In all probability the first gold mining to be done in the United States was in the gold region about Dahlonega, Georgia, or in the Carolinas, unless it was in some of the gold districts in southern California. Although the discovery at Sutter's mill, on the American river, in El Dorado county, California, was that which attracted the attention of the entire civilized world to California as a land of gold, it is well known that in Los Angeles county, and probably also in San Diego county, gold was washed from the placers by Mexicans and Indians long before Marshall's fortuitous discovery at Coloma.

From that day to this, California has not ceased to be recognized as a region of rich gold mines, nor has she proved disappointing. The golden output of California has reached nearly fifteen hundred millions of dollars.

California was the first school of gold mining and milling, and California practice, based upon the crude, almost barbaric methods of the Old World, came to be looked upon as exemplifying the best practice.

From oft-repeated praise the California millman, in time, really permitted himself to believe that he had actually attained an exalted plane. He became wedded to his practice, and, as he drew the lines still tighter, he grew more inflexible in his views. Innovations he abhorred, contenting himself with the results of his own limited experience. As years rolled by the early novice became the so-called old California millman, and a more autocratic (and we might also say automatic) individual has rarely existed. His judgment in milling matters was final; his word was law. "I have been running this mill for the last 30 years," he has been heard to remark, with ill-concealed conceit, "and you can't tell me anything about it."

When a man has been in one mill for 30 years, and nowhere else, it is about time for him to retire in favor of a younger man. Broad views and extensive knowledge do not come to those who get into a rut, and remain there for 30 years.

That the boastful millman did not always really achieve the high success he claimed is abundantly proved by the value of the tailing piles throughout the State, many of which have been re-treated by cyanidation and by other modern methods, at good profit.

For the most part, the ore of the gold veins of California is remarkably amenable to treatment by amalgamation, followed by concentration. This is the common practice throughout the State even today, and with rare exceptions, the tailing, after all, still contains a noteworthy quantity of gold, the greater portion of which should have been recovered in the mill.

The ordinary method of treatment is still much after the style of the ancient millman. The ore is delivered at the top of the mill to a breaker, though a few of the better equipped plants have the rock-breaker at the shaft or tunnel, or at some convenient point intermediate between the mine and the mill. From the bins the broken ore passes to stamps, the few exceptions being in the form of Huntington, Kinkead, or other type of rotary mill. The screens vary in mesh, but owing to the desire for large capacity per crushing unit, they are generally too coarse. The inevitable result is, in a large majority of cases, that the ore is not crushed sufficiently fine to release the valuable mineral from the gangue.

From the battery the pulp passes over silver-plated copper plates, often too limited in superficial area to accomplish the best results.

There have been volumes written on the amalgamation of gold-bearing ores. The experienced amalgamator has learned, if he has had his experience in more than one mill, that all ores cannot be treated in exactly the same manner. He must vary the amount of feed water, and the 'quick' must be fed according to requirements and not according to any rule. The ore from the same mine frequently varies in the different stopes, being more free in certain parts of the mine. Some ores may be crushed much coarser than others, without interfering with a satisfactory extraction by amalgamation. It is often a good idea to make experiments in the several batteries of a mill to determine what screen is best suited to the ore under treatment. It happens not infrequently that by employing a finer screen and lowering the discharge from two to four inches, a higher percentage amalgamation may be secured, while not reducing the capacity of the battery.

Another matter which requires careful attention is the feed of the battery; it should be adjusted and then watched to see that it is constant. Dry ore will usually run more rapidly than that which is wet. If the automatic feeding machines get out of adjustment, as they sometimes do, changes at once occur in the battery, on the plates, and on the concentrators. One of the fundamental principles of successful gold milling is an even feed of water and of ore. When these are secured a uniform set of conditions is established, and the duties of the mill crew are reduced to a minimum.

Extremists in the gold mill do not accomplish the best results. One feeds too much water or too much ore, or both, with too much or too little quicksilver. It is the rational, thinking man who does the best work. He watches his mill—every portion of it, and sees that each piece of machinery is properly performing its function, and also that the millmen each assume a proper share of the duties. It is a mistake to think that all that is necessary is to turn on the power and the mill will do the rest. Careful watching is needed even in the most automatic mill.

From the battery the crushed pulp falls upon the plates. There are many curious notions about the outside plates. These are too numerous to mention, but there are a few points worthy of emphasis.

The grade of the plates must be adapted to the ore, for the reason that it is not possible always to adapt the ore to the grade. The amount of water fed should be that quantity which will carry the pulp over the plate in a thin, even stream, allowing no bars of sand to accumulate. The water should be fed from a tank and be under constant head, or it will not supply a uniform amount. It is important to have abundant plate surface. Careful and exhaustive experiments made in the Homestake mills at Lead, South Dakota, have proved unmistakably that it pays to have large plate area. In those mills there are over 300 sq. ft. of silver-plated copper plates to the battery of five stamps —an unusual thing in any California mill, where the plates seldom exceed 80 sq. ft. per five-stamp battery, and are usually much less.

To accomplish the best results the plates must be kept in good condition constantly, and dressed as often as they require it. The condition of the plates is one of the most important factors in the free-milling of gold ores.

In most California mills, from the plates, the pulp, now supposed to be deprived of the greater part of the free gold content, is conveyed by launder to the concentrating machines, usually two for each battery of five stamps, because this is the common arrangement, and not because one may not be enough, or that more than two may not be necessary.

The pulp stream from each battery of five stamps is 'split' on a wedge-shaped wooden block placed on the launder, one-half going to one concentrator, the remaining half to the other machine. There is usually no difference in these machines, nor in their grade, speed, or amount of water employed, nor should there be, in consideration of the fact that there is practically no difference in the pulp going to either machine.

The fact was recognized many years ago, in Europe, that concentration of the minerals of high specific gravity from the lighter gangue minerals could not be accomplished successfully by a single operation upon one machine. In crushed ore containing sulphides of the base metals, or other valuable minerals of relatively high specific gravity, some of the ore particles, as well as the gangue, are coarse and some are fine. These grains range in size from the coarsest particles that will pass the screen spaces after crushing, to those of microscopic minuteness.

The relative size of the grains to be concentrated, and also the shape, are important matters. In the first place, the ore must be crushed sufficiently fine to liberate the grains of valuable mineral from the gangue. Having reduced the ore to the proper fineness, no matter what that may be, there always exists a wide range in relative size of these particles, and the problem is to separate both the coarse and fine and all intermediate sizes of valuable mineral from the coarse and fine and intermediate sizes of the particles of gangue. This is the problem of the concentrator man, and it has been solved almost to perfection, but not by the self-satisfied old-time millman. True, he has undertaken some improvements on the simple division of the pulp, and distributing the stream equally to the tables. He has first passed the pulp over a Wilfley or other table and then sent the tailing from this table over some of the numerous belt machines, such as the Frue vanner. This has been found an improvement in some mills, but the idea is still far from the proper method.

Another manner of improving the ordinary concentration methods in California practice is that of concentration in the usual way on two machines to each five-stamp battery, adjusting the machines so that they will save all of the sulphides—a difficult thing to accomplish, but a large percentage may be secured by saving at the same time a part of the sand liberated from gangue minerals. This dirty concentrate is then run over an extra machine for re-cleaning, and much of the sand is thus got rid of; but this operation always carries over some of the finest sulphides, and the result is not what had been hoped, nor, indeed, what is usually claimed for it.

As previously stated, the shape of the particles of both sulphides and gangue minerals is of great importance. In veins occurring in, or accompanied by, slate and schist there is often found a flat, flaky sulphide of iron, usually lower in grade in precious metals than that in the quartz, and yet too good to be thrown away. No concentrator made will save all of the granular sulphides and the flaky sulphides of the same diameter.

Panning after concentrators may not show the presence of sulphides in the tailing, and the millman is led to believe he is saving all that is valuable. This is because a first-class concentrating machine will do better work than is ordinarily done by panning, but the assay will detect the loss in the tailing from the machine.

At many California mines, the fact that these losses occur despite the best efforts of the millman has been long since recognized, and an effort has been made to curtail this loss by constructing elaborate slime-plants, consisting of an extensive series of inclined planes covered with canvas. In most cases a rude attempt is made at hydraulic classifying, in boxes of varied shape, but too small to effect proper separation. From these boxes, or classifiers, the coarse material passes out at the lower aperture, the fine overflowing at the top. It is the latter that is sent to the canvas tables, the coarse material from the bottom spigot being allowed generally to flow to waste, though still containing some gold.

Owing to the character of most of the California gold ore, there should be no use for the canvas slime-plant, if the proper sizing and hydraulic classifying arrangements were made between the crushing machinery and the concentrating machines.

If the stream of pulp from the amalgamated plates be sent to a pointed box or sizing cone, of proper size, where the coarser material passes out at the bottom, and the finer, slime-like portion overflows at the top, these two streams of material may be sent to separate machines of suitable design, and run at a speed determined by experiment as the most effective for the purpose, far better results would be accomplished.

The hydraulic-sizing device may be a plain settling cone or it may be provided, like the spitzlutten, with an upward current of water, which makes the separation of the coarse from the fine still more complete.

If the fine grains and slime containing both gangue and sulphides appear to require closer classification and separation this material may be passed through a second and larger classifier and three products made instead of two. Each of the several grades of classified material must be treated on a concentrating machine found by experiment to be adapted to it. The result will then be a high saving of the gold in the ore, with a consequent increase in profits; as the entire plant, when properly arranged, will be automatic.

Freiberg. According to E. V. Sturdy, attached to the British legation at Dresden, the considerable loss shown on the working of the mines is due principally to the approaching exhaustion of the silver and lead orebodies in the neighborhood of Freiberg, the result of the year's working being estimated at receipts, £42,800; expenses, £99,475, or a loss of £56,675, almost precisely the same result as the estimates for 1904-05 allowed for, though in each of those two years receipts were estimated at £55,035, and expenses at £121,535. The number of persons employed at these mines, which at the beginning of 1904 amounted to about 1,900, will by the end of 1907 be reduced to 1,300. If it were not for the renowned School of Mines established at Freiberg, whose students, drawn from all parts of the world and numbering many young Englishmen among their body, gain their experience in practical mining from underground work in the State mines; it is probable that by this time they would have been almost entirely abandoned, for, although the production of silver may still be reckoned at some 290,000 oz. annually, the cost of extracting this quantity is out of all proportion to its value.

From Australia comes the proposition to employ mica for the powder chamber of cartridges. The alleged advantages are that the quality of the powder could be judged through its transparent covering; that on account of the resistance of mica to heat the temperature of the gun would not rise so rapidly with firing as is the case when ordinary cartridges are used, and, finally, that in employing mica cartridges it would never be necessary to grease the breach of the gun.

Mining With the Steam-Shovel.

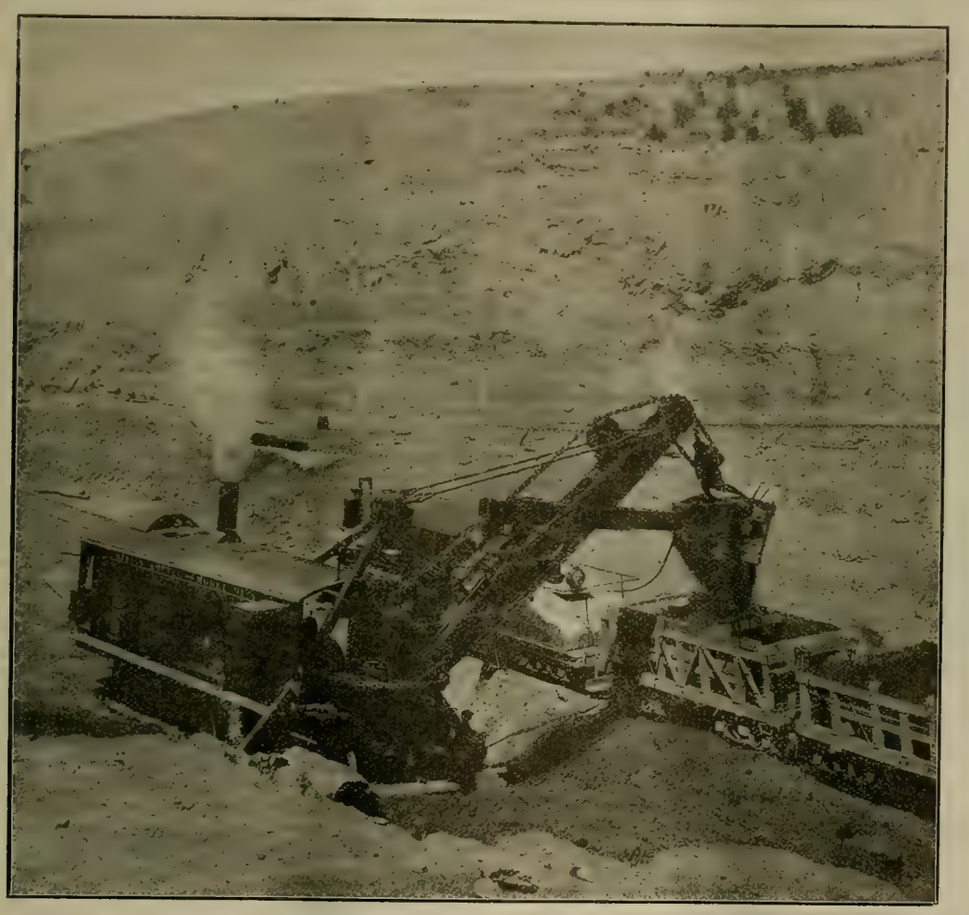
Written for the MINING AND SCIENTIFIC PRESS by DWIGHT E. WOODBRIDGE.

Mining iron ore by a steam-shovel is no peculiarity of the great Mesabi range, though it is generally so regarded. The development of that somewhat spectacular method on the Mesabi range has been so extensive and rapid that it has come to be regarded as typical of the district. Ore was mined by steam-shovel on older Lake Superior ranges long before the Mesabi was discovered, though only in a small way; it was the tremendous tonnages to be handled on the new range, not alone of ore, but of overburden, that caused the development of the steam-shovel in mining as it is at present.

When mine operators were confronted with the problem of opening the flat, comparatively shallow and quite soft ore deposits of the new range, all their previously acquired experience was at fault. Something new was demanded. The earliest experiments with a steam-shovel on the Mesabi were made by John T. Jones, a skilful and daring operator of the Menominee range, backed by P. L. Kimberley, of Pennsylvania iron-making fame. Mr. Jones had the proper idea, which was that one could go to far greater expense in stripping overburden than was admitted by most miners, if there were a sufficient thickness of ore beneath, and his plan of work on the Biwabik mine contemplated considerably more than the 40 to 50 ft. of stripping then considered safe. He was also alive to one very important factor of the situation—that there should be ample room to move cars away from the stripping and mining shovels; in other words, that the space on which cars and trains could move must be so great that there would be no serious delays in getting them to the shovels for their loads nor away when once loaded. One chief cost in steam-shovel operations has always been that of delay to the machine itself, handled as it is by skilled and expensive labor, while it is waiting for locomotives to get loaded cars out of the way and while empties are being spotted for their loads.

It is in this very point that the new plans for handling some of the large copper deposits of the West by the shovel will show a weakness, and fail, if they fail at all. For it is one thing to manipulate a train of dump-cars on a level space large enough for the entire train to be moved at once, passed along in front of a stationary shovel and loaded singly as they pass by; and quite another to get cars to a shovel placed on the side of steep arroyos, where there can hardly be room for turn-outs, and where everything must be handled from one end and over difficult grades.

Beginning with shovels not particularly adapted for the special requirements of the Mesabi situation, built by men not intimately acquainted with the difficulties to be overcome, the entire business has become highly characteristic, and is now as efficient, in all probability, as such a business can well be, considering the necessarily wasteful type of machine used. The shovel itself has become larger and stronger in many straining parts, auxiliary engines for special duties have been added, the booms have been adapted to the requirements of lifting to certain heights, to make a wider sweep, or dumping to a greater distance, and the shovel as a whole has become more and more self-contained. Some mining companies on the Mesabi are using a shovel weighing 105 tons and capable of lifting a dipper-load of six to eight tons, but the majority of machines in use are much smaller and lighter. In its large order for shovels last fall, the largest ever given by any private concern, the Oliver Iron Mining Co. fixed upon a weight of 90 tons for the machine and a capacity of 2.5 yards in the dipper. A yard of ore weighs about two tons. The Mahoning Ore & Steel Co. uses a shovel of about 65 tons weight and 1.75 to 2-yd. capacity. The Stevenson uses a 105-ton shovel and a 3-yard dipper. The majority of stripping and mining contractors in the Mesabi region use a shovel of from 60 to 80 tons weight. In stock-pile loading a slightly lighter machine can be successfully used.



THE STEAM-SHOVEL AS USED ON THE MESABI RANGE.

In the early days most of the engines and dump-cars used on the range were narrow gauge; dinkey engines and small cars. But this has all been changed and standard-gauge tracks are laid in almost every operation, while the dump-cars are quite elaborate affairs, costly, but efficient. In such operations as those on the Mesabi, there is no argument for gauges less than standard, and it is doubtful if there are many places where a steam-shovel can be economically used in which a narrow-gauge equipment is the proper thing. It takes not only power but weight to haul loads out of a pit in which the grades may reach 2.5 or 3%, and the dinkey engine is not successful.

The steam-shovel has done big work on the Mesabi range. In single years it has moved as much as 6,000,000 cu. yd. of waste material and mined 12,000,000 tons of ore. To this time the proportion of product excavated by shovel has varied up to about 56%, increasing as the years have passed; for 1906 the proportion will be greater, and it is assured that the percentage of shovel-mined ore will continue to increase. Although half of the ore output on this range two years ago was mined underground, and more than half produced since the beginning has been hoisted through shafts, it is safe to say that, were the Mesabi range to be opened new today, in the light of the experience acquired in the past few years, there would be scarcely a 'caved mine' from one end to the other; what few shafts might be sunk would be to connect with milling pits that had been opened from surface by shovel, and mined, in many cases, by shovel-loading at the bottom of some deep pit into tram-cars for the shaft. The tendency, in other words, is toward the exclusive use of open pits of one form or another. This is due to several causes; the increased efficiency of shovels, reducing costs of handling dirt; the higher value and greater scarcity of suitable mine-timber; the inefficiency and unreliability of common labor and its continual liability to go back on the operator at times when he is in especial need of a big product. The shovel never goes on strike, though it sometimes breaks down, its employees are few and of a class quite different from the ordinary laborer.

In mining ore the larger steam-shovel mines of the range have achieved products of from 30 to 100 tons per day per man, the variation being great on account of the diversity of conditions. Last season one shovel at the Hull mine in 335 minutes loaded 4,140 gross tons from the stock pile. A 25-ton car is usually loaded in three or four minutes. Three shovels at the Burt open-pit in ten hours loaded 18,000 tons from the natural bed. The Mahoning mines handle about 1,000,000 tons per annum with three shovels in ore, and these three working but part of the time; it could easily produce as much more, if required. The Biwabik mined last year 1,100,000 tons with three crews operating five shovels. Not more than three shovels could be worked at one time, and the larger number was in place simply to permit the mixing of ore in the pit to reduce ores to the guaranteed grades. These tonnages are handled in about seven months. In one ten-hour day at this mine three shovels loaded five hundred 30-ton railway cars, 15,000 gross tons. At the Stevenson one 105-ton shovel loaded 7,109 tons in ten hours, at the Burt one 93-ton shovel loaded 5,096 tons, while at the Mountain a machine of the same size and make loaded 4,826 tons in that time. To be sure, most of these are far above average runs; they are record operations and have little bearing on what is the ordinary duty. In almost every case the ore ahead of the dipper is loosened by charges of black powder blasted in holes that have been drilled and then 'sprung' by a few sticks of dynamite; but this preliminary is not infrequently omitted, and the ore is often taken from the natural bed as it has lain since originally formed. Contracts for mining ore have been taken at 10c. per ton, and there is understood to be good profit at that price.

In stripping overburden the steam-shovel contractors have been working successfully under agreements running from 30 to 40c. per yard and averaging, say, about 32c. There is, of course, a profit at this price. Cost sheets sometimes show as low as 18.5 to 19c. per yard. Operations are largely dependent on weather conditions, the supply of labor and the excellence of superintendence, which varies greatly. The length of run to waste-banks, the grade out of pit and on to bank, the character of stripping, whether it contains much boulders, hardpan, etc., or is chiefly soil and clay, are all important items; and even the time of year in which the work is carried on has a noteworthy influence. It was formerly thought that winter stripping was the more costly, but that opinion is giving way and must become obsolete in time. From 28 to 30 yd. of spoil per day per man is a fair average. For 20 hours' continuous work one shovel and its attendant trains will move from 1,500 to 2,000 yd. of material, and a shovel and attendant trains will use, say, 75 men on two shifts. Larger mining companies now do much of their own work.

Companies operating shovels are installing well-equipped machine shops for repairs, so these may be attended to close by and in the least time. It is rather important that breakages may be fixed on the spot, rather than wait the leisure of some distant erecting shop full of its own work, or pay the cost of long carriage by express.

The question of how much surface may be taken off the orebody with economy is an ever present one on the Mesabi. In the copper mines of Bingham, at the Cactus, Ely, and other points where it is proposed to utilize this machine, there need be no such question, for the overburden is so slight as to be unworthy of a moment's consideration. Over the Bingham monzonite ores it runs but a few feet, and is even less, I understand, at Ely. At Granby, too, the surface is very slight, though more than at Bingham.

Only one determined effort has been made to oust the steam-shovel from its lead as a remover of overburden and miner of ore. This is by the well-known firm of Hoover & Mason, of Chicago, who are erecting, at the

Grant mine of the Interstate Iron Co., a great overhead clamshell contrivance. It is hung on a cable stretched between a pair of movable towers each 150 ft. high and placed 1,100 ft. apart. The clam weighs 25 tons, and is supposed to take up a load of the same weight. It has not come into service, but will be tested in a few weeks, and should be in operation during the summer. No criticism of the machine is advisable, though the general opinion is somewhat adverse, as yet. But the fact remains, that if a shovel had been put at work on the Grant overburden when the construction of this machine began, the Grant might have been a large shipper this year, while now it can scarcely put out any considerable tonnage before 1907. And the first cost of the shovel outfit would have been but a fraction of the investment this machine represents.

I have said only one determined effort; there remains the scheme for an electrical shovel taken up a year ago in a rather vigorous manner, but for some reason it has been permitted of late to drop into a state of innocuous desuetude, to be taken up vigorously, perhaps, later, when those interested have more time on their hands. Some engineers have recommended a shovel operated by compressed air, but this seems absurd, in the light of conditions prevailing at open pits. Electrical operation of shovels, where water-power is available, ought to reduce costs materially.

Quartz Blout.

In a valuable geological report on the Ely district, Nevada, entitled 'The Copper Deposits of the Robinson Mining District, Nevada,' by Mr. Andrew C. Lawson, professor of geology in the University of California, the author introduces a new term, which he defines in the following paragraphs:

Perhaps the most remarkable feature of the porphyry is the occurrence, in the areas occupied by the latter, or on their periphery, of large bodies of quartz of somewhat varying character. These bodies of quartz are by no means uncommon features of decomposed and mineralized eruptive rocks in Nevada and elsewhere; and the prospectors and miners, who have to deal with them practically, usually distinguish them from ordinary vein quartz by characterizing them as 'blow outs.' This discrimination appears to the writer to be well warranted. They cannot be regarded as veins or lodes; and while, as will be shown later, they are to a large extent replacements of other rocks, they may not be wholly so. They constitute a particular mode of occurrence of quartz which the writer desires to distinguish both from vein quartz and from replacements of country rock by silica in the vicinity of veins. To signalize the distinction and to simplify their discussion, the miners' term 'blow out' will be adopted in the modified form of 'blout,' and they will, therefore, be referred to henceforth as 'quartz blout,' much in the same sense as one would use the expression 'quartz vein.' Similarly as we designate the quartz of a vein specifically as 'vein quartz,' so here we may refer to the quartz of which the blouts are composed as 'blout quartz.'

The most striking feature of these quartz blouts is their vast size as compared with ordinary veins. A glance at the map will show that in the vicinity of the Ruth mine they occupy a very considerable fraction of the area of the porphyry; perhaps one-third is occupied by the blout.

The mapping indicates that the greater part of the quartz blout lies on the periphery of the porphyry mass and occupies an intermediate position between it and the surrounding limestone; and although some important occurrences are more centrally situated, these from the mapping appear to be of the nature of caps upon the hill tops and ridges. If we accept the suggestion thrown out in an earlier portion of this paper, that the porphyry mass is of the nature of a laccolith, then these centrally situated quartz blouts are also peripheral, and represent a contact development between the porphyry and its roof of limestone now removed by erosion. Indeed, we can form a very consistent hypothesis to explain the distribution of the blouts by supposing that they were once a more or less continuous envelope, incasing the porphyry, particularly on its upper side, and intervening between it and the over-arched roof of limestone. The removal of the limestone roof by erosion and the dissection of the envelope of quartz blout, leaving exceptionally thick or resistant portions of it as residuals reposing upon the porphyry, would well explain these occurrences.

Waldemar Lindgren of the United States Geological Survey will spend about two weeks the coming summer, in picking up the scattered threads of an investigation which he began last year of the mining districts of New Mexico, but which was interrupted by early snows.

The Effect of Temperature on Amalgamation.

By Thomas T. Read.

In a paper to be read before the American Institute of Mining Engineers, entitled 'The Amalgamation of Gold Ores,' Mr. Thomas T. Read, of Columbia University, gives the results of his investigation of direct changes in amalgamation due to temperature. The following is an abstract verbatim:

Whether variations of the temperature at which the process is conducted have any direct specific effect on amalgamation, has been the subject of much discussion. It will be impossible to refer here to all the statements made regarding this, but a few of the more significant must be mentioned. J. A. Grier[1] states that when two batteries were run side by side on the same ore, the one at 50°F. and the other at from 60° to 70° F., considerably more gold was caught by the battery at the lower temperature. J. A. Church[2] cites a case where water from old mine-workings was used that had a temperature of 135° F., at the battery; the plates coated badly and the recovery was very poor. T. A. Rickard[3] says that at Black Hawk, Colo., the recovery is better in winter than in summer, and objects to the practice at the Brittania United, Ballarat, of warming the battery-water. Louis Janin[4] says that no advantage is gained by heating the battery-water. At the Golden Star mill, Supt. Reed[5] changed a battery from 56° to 70° F. In 24 hr. the amalgam had nearly all scoured off. This was a silver plate; the copper was not affected. It is not stated whether all other conditions were kept constant, and it is hardly safe to comment on such an experiment unless all the conditions are known. J. A. Sanborn[6] says that the objection to an increase in temperature is that the plates were prepared for a lower temperature, but that the adjustment may be made for any reasonable temperature. He also says that the chief objection to hot battery-water is the resultant increased solubility of deleterious salts. J. H. Thierman[7] suggests that the heated water causes any grease which may be present to more readily form a film over the gold and mercury. A. von Dessauer[8] found that the plate-amalgam contained from 20 to 35% of gold in the summer time, but only from 7 to 10% in winter. Besides these factors, R. H. Richards[9] mentions two others, the attraction of mercury for gold and the cohesive power of the mercury. It should be noticed, however, that the only attraction mercury has for gold is the surface-tension pull; and that the facilitation of the coalescence of globules of mercury by a rise of temperature is not due to an increase of cohesive power, but to a decrease of their surface tension.

To determine whether other physical constants are appreciably affected by temperature changes, two lines of investigation were followed. The purpose of the first was to learn whether the plasticity of the mixture of liquid and solid, ordinarily known as 'amalgam,' varied to any degree with ordinary ranges of temperature.

For this purpose an apparatus was designed and constructed, in which a pasty mass of amalgam was held in a cup that was rotated by a small electric motor. The cup was provided with sharp points on the inside, so that the amalgam was obliged to rotate with it. Submerged in the mass of amalgam was a stirrer, turning in a ball bearing. The torsional pull on the stirrer, when the mass was rotated, was measured by a delicate helical spring. The whole apparatus was placed in a constant temperature chamber, and numerous observations made over the range from 18 to 100° C. (60 to 212° F.). Both silver and gold amalgams of the consistency of thick cream were used; it was necessary to employ very finely divided metal in preparing the amalgam in order to make it homogeneous. It was found that, as a result of the increase of temperature, two conflicting changes tended to take place: The amalgam tended to become harder from the increased absorption of the mercury by the gold, and softer from the decreased viscosity of the liquid mercury cementing the solid particles. The total change was very slight, and of the same order as the errors of observation due to the settling of the solid particles and the slight imperfections of the apparatus. A more detailed statement of the results, and a sketch of the apparatus, are therefore omitted. The investigation showed that the changes in plasticity induced by ordinary variations in temperature are negligible.

The purpose of the second investigation was to learn whether the adhesion of gold to mercury is sensibly affected by changes of temperature. To this end the inclination at which spheres of gold, silver and platinum, one-half an inch in diameter, will roll down an amalgamated copper-plate were observed. Two sets of angles were measured; that at which the spheres would start to roll from a state of rest (column A), and the angle at which they would continue to roll after being started by a touch from a camel's hair brush (column B). The inclination was measured for the dry plate at ordinary temperature (20° C.), the amalgamated plate at the same temperature, and the amalgamated plate at 100° C. The gold and platinum spheres were perfect to within 0.001 in.; the silver sphere was not so perfect, and gave more irregular results. The angles recorded are the average of several observations. The plate was somewhat roughened by the action of the mercury at the higher temperature; this is especially noticeable in the angles at which the balls would start themselves. The gold and silver balls were previously amalgamated for the determinations with the amalgamated plate, but the platinum ball, of course, was not.

Results of Adhesion Tests of Gold, Silver and Platinum Balls.

	Platinum.		Gold.		Silver.	
	A.	B.	A.	B.	A.	B.
Dry plates, 20°....	1° 28′	0° 28′	1° 09′	0° 32′	2° 17′	0° 48′
Wet plates, 20°....	1° 45′	0° 28′	1° 48′	1° 15′	3° 07′	1° 57′
Wet plates, 100°...	1° 43′	0° 54′	2° 03′	1° 30′	.....	1° 30′

These facts are so completely in accord with the data obtained by the metallurgical and chemical investigations, that there seems no escape from the conclusion that amalgamation of gold ores is mainly, and above all, a simple mechanical process. Such chemical forces as enter into it are only slight, and are mainly detrimental. The chief physical factor is the surface-tension of the mercury, which causes the mercury to cling in an adherent film to the plates employed, to wet the gold grains, and to draw them beneath its surface. It also acts detrimentally, tending to prevent the globules of mercury from coalescing again when they are very finely divided. The solution of the gold and silver by the mercury is very slight indeed; that of the copper is more noteworthy, and gives opportunity for undesirable chemical action. The absorption of the mercury by gold, silver and copper is large in amount. With gold, what is probably an inter-metallic compound is formed with excess of mercury at 100° (whether it can form at ordinary temperatures is not certainly known), but this is of no great importance in the ordinary application of the process. Some sort of molecular flow causes the grains of the amalgam to adhere strongly together on standing, and the slow diffusion of the gold into the plate causes the amalgam to adhere strongly to copper and silvered plates. According to Richards[10] this diffusion does not extend to any great depth in the ordinary life of a plate.

The effect of changes in temperature on amalgamation is seen to be two-fold. The solubility of deleterious salts in the ore is, of course, increased by rise of temperature, their action is accelerated, and the solubility of copper in the mercury is increased, thus giving greater opportunity for these harmful reactions. But the most important effect is the disturbance of plate-equilibrium, resulting from changes of temperature. The thickness of the film of mercury which the plate will hold, and the absorption of mercury by the other metals concerned is changed, and the mill-man then has to deal with varying conditions, a state of affairs to be avoided, if possible. From the physical standpoint the temperature employed does not matter, so long as it is constant. From the chemical standpoint a low temperature is better in most cases. But it should be mentioned, in passing, that both the viscosity and surface-tension of mercury are lessened by rise of temperature, the differences for ordinary ranges of temperature being slight. Under certain circumstances, where chemical action is negligible, it seems that it might be advisable to conduct the process at elevated temperatures, for the wetting of the grains by the mercury is slightly facilitated by rise of temperature. The viscosity of mercury at 0° is 0.0169 dynes per sq. cm., and at 99° is 0.0123 dynes per sq. centimeter.[11]

In the operation of the stamp-milling process the character and gold content of the ore necessarily vary. If, in addition, the temperature, and with it all the foregoing factors, are allowed to vary, it becomes impossible to exert a proper control over the operation.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rock specimen from Unionville, Nev., marked R. L. P., is calcareous sandstone.

The rock from Eureka, Nev., marked T. P., is silicious metamorphic rock—possibly silicified limestone. Rocks of this character are of frequent occurrence in limestone regions that have been subjected to the intrusion of dikes and the infiltration of mineral-bearing water.

The rocks from Kingman, Ariz., are: No. 1, Granite, in which both biotite and hornblende are present; No. 2, a basic hypersthene rock, probably Basalt; No. 3, partially devitrified volcanic glass; No. 4, Basalt; No. 5, Rhyolite; No. 6, Rhyolite; No. 7, Quartz-porphyry; No. 8, Rhyolite; No. 9, Rhyolite, with numerous amygdules containing chalcedonic quartz; No. 10, Rhyolite tuff; No. 11, Rhyolite; No. 12, a silicious rock, apparently the result of alteration of some other rock (probably Rhyolite); No. 13, opalescent silica, also the result of alteration.

The rocks from Table Rock, Cal., marked T. G., are: No. 1, Quartz with limonite; No. 2, Quartz and feldspar with iron oxide, evidently from a pegmatite vein; No. 3, a much altered and iron-stained dike rock, probably Diorite; No. 4, Serpentine; No. 5, silicified and decayed dike rock, also originally Diorite; No. 6, a much kaolinized eruptive rock, in which only the hornblende remains slightly unaltered; No. 7 is Feldspar-porphyry and affords a hint as to the original character of No. 6, which was probably similar to No. 7; No. 8 is a metamorphic rock containing much iron oxide. None of the rocks of this lot are typical, and nearly all are so much altered as to make their identification somewhat doubtful, the only exceptions being No. 4 and 7.

A New Map representing parts of California and Mexico has recently been published by the United States Geological Survey which is of unusual interest at this time. The area covered is widely known as the Salton Sink, a great depression in the Colorado desert which has been much discussed lately, owing to the threatened formation of a large inland sea where there is now a thriving community. About 8,000 people have settled in that part of the basin known as the Imperial valley and are raising excellent crops of barley and alfalfa. Stock farms are numerous and experiments in raising the date palm are in progress. The freight shipments from Imperial, a town only four years old, rival those of Los Angeles in value, and are said to exceed those of any other town in southern California. The existence of this peaceful community is however seriously endangered by Colorado river which strangely enough is also the source of all its prosperity as it is this stream which furnishes water for the irrigation system. The absence of any controlling works at the head of the main canal has resulted in diverting the river from its old channel and permitting the entire flood flow to enter the irrigation system. This is causing great damage to the ditches and crops, and is forming a large lake, which now covers about 250 square miles, at the lowest part of the sink. The Southern Pacific railroad has been obliged to rebuild many miles of tracks. The map of this region, which is called the Salton Sink special, shows on a scale of about eight miles to an inch, all the principal towns, roads, canals and drainage lines. Contour lines also indicate what the future sea may cover at different altitudes. The usual price of five cents a copy will be charged for this map, which was made by Mr. W. Carvel Hall, under the direction of Mr. R. B. Marshall.—From 'Science.'

Transporting a Boiler.

The accompanying illustration shows a boiler being taken across New Mexico by a novel method. It is a 125-h.p. Scotch stationary boiler, built by the Kingsford Foundry & Machine Works, for the Marine Hospital at Fort Stanton, New Mexico. It was necessary to transport the boiler for a distance of nine miles across the plains and mountains, and as the roads were in a condition rendering impossible the passage of a wagon with such a heavy load, it was found necessary to rig up the boiler as shown. A heavy pipe was used as an axle, and mules furnished the motive power. The picture shows the boiler on level ground just before entering the station.

The Volumetric Estimation of Antimony.

Written for the MINING AND SCIENTIFIC PRESS by JAMES DARROCH.

All of the gravimetric methods of estimating antimony are tedious and many of them are unreliable, while the dry assay, although fairly expeditious, is notoriously inaccurate. When sodium thiosulphate (hypo) solution is used in the titration, the iodide method cannot be relied upon, as the hypo is decomposed, with the separation of sulphur, by the strongly acid solutions which must be employed.

The method described below gives excellent results with all ores and alloys containing antimony, and it is much more accurate than any of the gravimetric methods so often employed in estimating that metal, while it possesses the further advantage of being almost, if not quite, as speedy as the dry assay. This process is similar to the iodide method mentioned above, the principal exception being that a standard solution of stannous chloride is substituted for the thiosulphate solution generally employed in the titration.

The determination of antimony by the iodide method consists of estimating the amount of iodine liberated when potassium iodide is added to a solution of antimonic chloride. It is essential for the success of this process that all of the antimony should be converted to antimonic chloride ($SbCl_5$), while free chlorine must be completely absent from the solution, which should be kept strongly acid.

The assay is conducted as follows: From 0.5 to 1 gram of the finely crushed ore, which should pass a 100-mesh screen, is dissolved in strong hydrochloric acid, with the addition of a few crystals of tartaric acid, heat being applied until no further action takes place. When the antimony is completely in solution, the assay is diluted to about 300 c. c. and a brisk current of sulphureted hydrogen is passed through the liquor until it is thoroughly saturated. After the antimony has all been precipitated, the sulphide and insoluble residue is filtered off and washed two or three times with water containing sulphureted hydrogen. The filtrate, which contains the iron, etc., present in the ore, may be discarded.

The filtering and washing should be done as quickly as possible, as the antimony sulphide is liable to decompose and again go into solution on exposure to the air.

The bottom is now knocked out of the filter, and the precipitate washed into a flask. About 100 c.c. of strong hydrochloric acid with the addition of a sufficient quantity of potassium chlorate to completely convert the antimonious chloride to antimonic chloride, are now added to the assay, and the solution is then boiled until the sulphide has dissolved. After free chlorine has been entirely eliminated the assay is allowed to cool, and, when cold, about 5 grams of potassium iodide is added to it. Iodine is liberated by the antimonic chloride in accordance with the reaction:

$$SbCl_5+2KI=SbCl_3+2KCl+I_2$$

The assay will assume a brown color, due to the iodine liberated, but should contain no precipitate as antimonious chloride ($SbCl_3$) is soluble in strongly acid solutions.

The solution should immediately be titrated with a standard solution of stannous chloride, and, during titration the assay should be thoroughly shaken. The color is gradually discharged as the stannous chloride is run in, and when it has become pale, a few cubic centimeters of freshly prepared starch solution are added, and the assay well shaken. A deep blue color is at once produced, and the titration is continued until this is discharged. The end reaction is very sharp, even sharper than in the iodic method of determining copper, and, consequently, the titration should be done cautiously as this stage is approached. When the reaction is complete the assay should be quite clear except for the insoluble residue. The blue color generally reappears on standing a minute, but this is due to secondary decomposition, and may be disregarded. It is discharged by the addition of a single drop of the stannous chloride solution.

The stannous chloride reacts with free iodine in the presence of hydrochloric acid thus:

$$SnCl_2+I_2+2HCl=SnCl_4+2HI$$

The volume of the standard solution of stannous chloride required for titration × standard of same = the weight of antimony in the sample taken for assay.

Therefore the percentage of antimony present is found by the following calculation:

$$\frac{\text{Standard x number of c. c. stannous chloride solution required}}{\text{Weight of ore taken for assay.}} \times 100 =$$

per cent of antimony in the ore.

Since copper and arsenic also liberate iodine, and as bismuth iodide resembles free iodine in color and would therefore interfere colorimetrically in the titration, these metals, if present, must be removed from the solution. The copper and bismuth may be separated by washing the combined sulphides on the filter with a solution of sodium sulphide; the arsenic by boiling the sulphides of arsenic and antimony with strong hydrochloric acid. Tin does not interfere, as it would be present in the stannic condition only.

TRANSPORTING A BOILER UNDER DIFFICULTIES.

The solutions required for the assay are:

Standard solution of stannous chloride. This is prepared by dissolving 10 grams of stannous chloride in hydrochloric acid, and diluting to a liter. This solution should be kept under paraffin as it oxidizes very rapidly.

Standard solution of antimonic chloride for standardizing. This solution is used to standardize the stannous chloride solution, and it is prepared by dissolving 0.2 gram pure antimony in strong hydrochloric acid and potassium chlorate. This must be done in the cold, as antimony is almost quite insoluble in hot hydrochloric acid and potassium chlorate. When the antimony has dissolved, the solution is boiled until free chlorine has been eliminated, allowed to cool, potassium iodide added, and titrated with stannous chloride in the same way as described for the assay. The antimony equivalent of the stannous chloride solution is found by the calculation:

$$\frac{\text{0.2 gram antimony.}}{\text{Number of c. c. stannous chloride solution required for titration}} =$$

the amount of antimony (in grams) represented by each c.c. of the standard stannous chloride solution.

Starch solution. This is prepared as for the iodide method for copper. It must be fresh and free from floating particles.

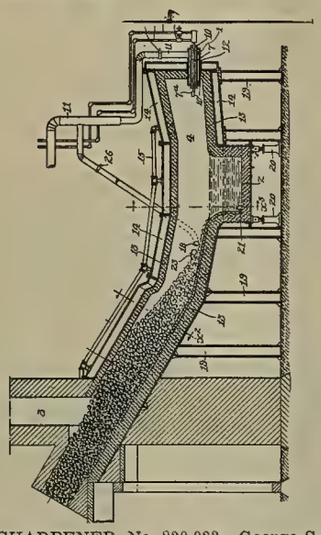
An instrument of precision is not an absolute necessity in keeping a shaft in alignment. Frequently inclined shafts are allowed, through carelessness, to get badly out of line. All that is required is to keep the hoisting rope midway between the track-rails or skids, and the shaft will be true enough for all practical purposes.

Mining and Metallurgical Patents.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

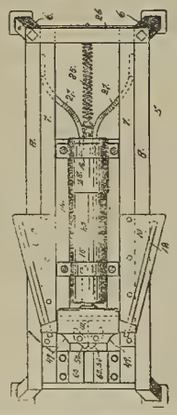
PROCESS OF SMELTING ORES, No. 820,134. Elfego Riveroll, Los Angeles, Cal.

The process for treating ore which consists in feeding and supporting the ore on an inclined surface, allowing the ore to move downward on said surface by gravity, arresting the downward movement of the ore at a definite position, applying a blast of hot gases against the lower end of the body of ore, confining said hot gases to cause them to pass upwardly through the body of ore, withdrawing the hot gases from the body of ore before they reach the point at which the ore is fed to the inclined surface, and applying a supplementary blast of air to the body of ore between the point of application of the hot gases and the point of withdrawal of the hot gases and allowing the fused ore at the lower end of the body of ore to drain from the unfused ore, and maintaining the fused ore in heated condition to enable the metallic portion thereof to separate from the slag.



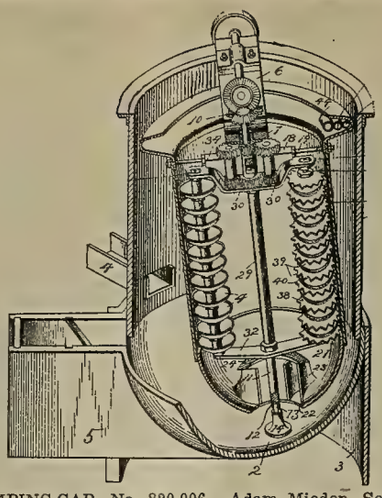
DRILL-SHARPENER, No. 820,023. George S. Spreyer, Elkton, Colo.

The combination with a suitable frame, of a spring-held casing, a slidable support therefor movable back and forth on the frame, yielding means connected to act on the support whereby the casing is normally held at its forward limit of movement, a hammer mounted to reciprocate in the casing, means for imparting a reciprocating movement to the hammer through the instrumentality of a suitable operating fluid, a chuck connected with the casing and arranged to be acted on by the hammer, the chuck having a limited movement in the casing, sharpening-dies laterally movable in the chuck, and means connected with the dies for causing the latter to recede from each other as the chuck and casing are moved rearwardly in opposition to the yielding means acting thereon, and arranged to be rendered effective by the rearward movement.



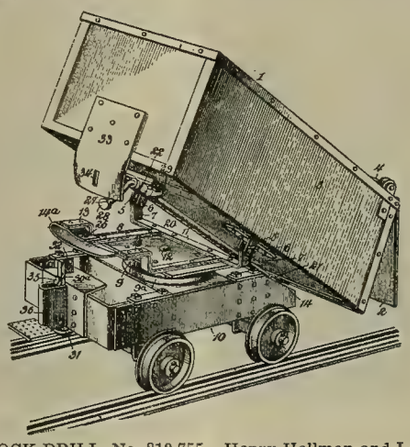
ORE-SEPARATOR, No. 820,568. Hiram C. Groves, Woodward, Okla.

In an ore-separator the combination with a casing having an inlet; of an inclined bowl rotatably mounted within the casing and having an inlet in the bottom thereof, curved means for whirling liquid upward through the opening and against the wall of the bowl, agitating devices at one side of and staggered in relation to the axis of the bowl and movably mounted within the bowl and means for operating said bowl and the agitating devices.



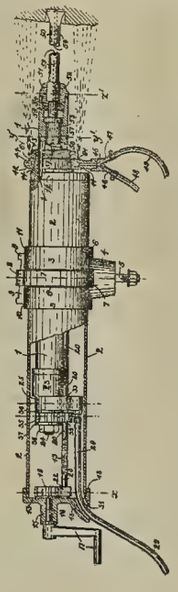
DUMPING-CAR, No. 820,006. Adam Mieden, Seattle, Wash.

In a device of the class described, the combination of a truck-frame having a turn-table or support provided with a horizontal supporting-plate, a transverse bar mounted on the plate at the front of the same and having upwardly-extending arms, a tilting body having a door and pivoted to the said arms, rearwardly extending arms projecting from the back of the plate, locking mechanism mounted on the body for holding the door in its closed position, and means carried by the rearwardly-extending arms for operating the locking mechanism.



ROCK DRILL, No. 819,755. Henry Hellman and Lewis C. Bayles, Johannesburg, Transvaal.

In a rock-drilling machine or engine, in combination, a casing, a power-cylinder therein, a cap fixed at the rear end of the power-cylinder, formed with a rearward extension, a swivel arranged on said extension and adapted to admit the motive fluid through said extension to the power-cylinder, a pipe for conducting the motive fluid to said swivel, packings arranged at either side of said swivel to prevent the escape of the motive fluid from between the swivel and the extension upon which it is arranged, and screw connections leading from the outside of the cap and passing through the swivel, for moving the power-cylinder.

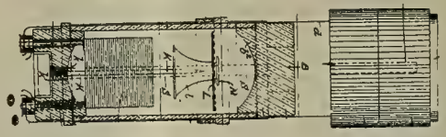


CORE-DRILL, No. 821,130. J. M. Smith, Reynoldsville, and R. M. Downie and F. W. Ransom, Beaver Falls, Pa.

The combination with a tubular reciprocatory drill-stem having a percussion-cutter at its lower end, of a tubular core-holder located within the stem and having a free longitudinal movement in the same, the lower portion of said tubular core-holder being movable freely through the percussion-cutter, and a spring engaging the holder and urging the same through said percussion-cutter.

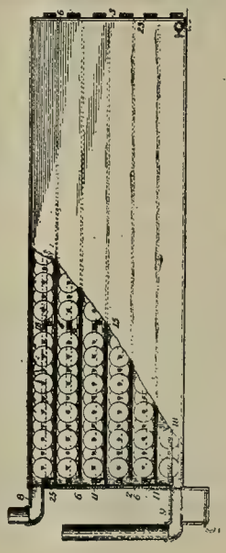
MEANS FOR SURVEYING BORE-HOLES, No. 821,048. H. F. Marriott, Parktown, Transvaal.

In an instrument for surveying bore-holes the combination of a magnetic compass constructed with a bell-shaped base, a vertical needle on the extremity of which said compass-base is supported, a mirror carried by the compass, a resistance-coil below the compass, a substance surrounding said coil which substance is liquefiable by the passage of a current of electricity through the coil, said substance serving on resolidification to retain the compass in the position it assumes when the substance is liquefied at the point to be surveyed, wires or conductors for passing a current of electricity through the coil, and a casing for inclosing the several parts of the instrument constructed with a longitudinal feather or projection and fitted with a diaphragm for supporting the instrument in the casing.



AMALGAMATOR, No. 821,108. A. G. Macdonell, Chevy Chase, Md.

An amalgamator comprising a substantially closed tank, partitions therein arranged to afford a tortuous passage through the tank, removable plates having amalgamated surfaces which completely inclose said passage, vertical disks arranged in said passage parallel with the direction of flow of the liquid passing therethrough, and means for imparting motion to said disks.



Special Correspondence.

LONDON, June 6.

That substantial progress is being made in the Colony of British North Borneo is proved by the particulars given at the general meeting of the British Borneo Exploration Co. Ltd. held this week. In the course of his address the chairman, Mr. Edmund Davis, said the company was formed in February of last year with a capital of £500,000, divided into 400,000 ordinary shares, and 100,000 founders' shares of £1 each. The total subscribed working capital was £100,000, £20,000 having been so far called up, leaving £80,000 still uncalled. The concession acquired by the Company gave exclusive rights for a period of 50 years to explore for minerals, etc., in British North Borneo, some 31,000 square miles. At the outset of the Company's operations they were in the fortunate position of becoming the owners of large deposits of manganese ore, a mineral of which the world's annual production was as near as possible 1,000,000 tons. They had shipped sufficient material to construct eight miles of railway with 35 lb. rails, and five miles with 16 lb. rails. Some 30,000 tons of manganese had been sold for future delivery, the buyers having the option under certain conditions of taking a further 38,000 to 40,000 tons as soon as available. In addition to manganese, large deposits of iron had been discovered, and deposits of coal were reported quite close to the manganese. Oil was being worked in Dutch Borneo on a large scale, as much as 9,000 tons per week of crude oil being produced at the present time. An option had been given to certain responsible parties to form a syndicate for the exploitation of the oil rights. Referring to the manganese ore deposits the chairman informed the meeting that they were constructing a metre-gauge railway of between five and six miles in length, with 35 lb. rails and with branches of 18-in. gauge, with 16 lb. rails, to connect some of these deposits with the coast, where a jetty had been constructed to afford shipping facilities. The deposits are principally situated in the hills, reaching up to about 1,000 ft. in height, and chutes are in course of construction for the purpose of bringing down the mineral to the railway. The seams of ore vary from 1 to 6 ft. thick, and though generally covered by a layer of clay or chert, are easily mined, being principally near the surface. The Borneo manganese ore has an exceptionally low percentage of phosphorus and sulphur. The same can be said of the iron ore, the various samples of which show an average of 63½ per cent metallic iron, and there are about 1,500,000 tons already exposed. As regards coal it is reported that large quantities are available 15 miles from the manganese mines.

Although little interest is taken by the public in West African matters, the 'Daily Mail' wishes to make known that the industry itself is making steady progress. To the ranks of the half-dozen producing properties will be added three more in the not distant future. The Prestea Block A should have its 50-stamp mill in full working order by the end of July, with a two years' supply of ore ready for crushing. The Attasi finished its 15 miles of tram-line from the mine to Dunkwa, on the Gold Coast Railway, in December last, and has since been erecting a mill of 50 stamps with cyanide plant capable of treating 6,000 tons per month. The end of July should also see this property at work with 20 months' supply of ore. The Taquah is also engaged in putting up a new plant, and its 50 stamps should be dropping early next year, when it is expected some 170,000 tons of ore will be ready for treatment. Working costs in West Africa are undeniably heavy. As more properties reach the producing stage, an appreciable reduction in store expenses should be made, but there is still great dissatisfaction at the abnormally high rates on the Gold Coast Railway.

The 'Australian Mining Standard' furnishes the particulars of the Australasian gold production for the first quarter of the current year. Here is the comparative statement in detail:

Returns for March Quarter.	1905: Fine oz.	1906: Fine oz.
West Australia	480,401	452,366
Victoria	161,057	177,494
Queensland	133,922	115,248
New Zealand	117,754	123,325
N. S. Wales	69,906	77,337
Total	963,040	945,770

It is seen that the West is behind by 28,035 oz., while increases are shown by three out of the five contributing States.

The crowded meeting of Oroya Brownhill shareholders last week, presided over by Mr. George P. Doolette, reflected the brilliant position of the Company. Referring to the accounts the chairman pointed out that the output of gold for the year was £653,485.18.9, the cost of winning it being £141,848.3.7. The amount distributed for the year and as a bonus on the previous year's working was £438,750, which represented nearly the whole of the nominal capital of the Company. The payment of the bonus in the year 1905 was made so as to bring the dividends for the previous year up to the uniform rate of 16s. per share, which he hoped they would maintain for years to come. The reduction in costs had been a feature of the year's work; when the managers, Bewick, Moreing & Co., took charge of the mine at the time of the amalgamation, the costs were 43s. 3d. per ton; today they were down to 22s. 4d., with the possibility of a still further reduction. This reduction, compared with the average for 1905, will mean an additional profit of £15,000 to £20,000 per annum to the Company. The chairman had good reason for saying that the year in many respects had been a record one. He thought the treatment of 112,713 tons of ore, of the average value of 27 dwt., would take some beating. While, of course, other mines are treating a much larger tonnage, he questioned if any mines in the world can beat their record as to value. It was the intention of the management to bring down the average value of the ore treated without in any way interfering with the rate of dividends now being paid, namely 16s. per annum, or at the rate of 30 per cent on the capital value of the stock. Having this year written off the whole of the developments and main shaft account, together with £28,000 from machinery and plant, and in view of the reduced provision which will in future be required for depreciation, they could reduce the average value of the ore treated and yet maintain the present rate of distribution for a much longer time. Dealing with the developments, the chairman remarked that in the upper levels of the Brownhill lease, as also in many other places in the mine, they had been opening up large quantities of low-grade ore; ore which, a short time ago, was not considered payable, but which under present conditions can be treated at a profit. The Brownhill leases had been a veritable widow's cruse to the Company. At the time of the amalgamation this property was considered to be little more than a shell, containing something like 55,000 tons of ore, whereas up to the present time the mine had contributed 150,000 tons of ore, being nearly one-half of the total tonnage treated, and the Brownhill leases would continue to supply ore to the mill for some time to come. The most important discovery in the mine during 1905 was the branch from the rich shoot which was discovered at the fifth level, 50 ft. east of the main north drift, where ore, 5 ft. 3 in. wide, was driven on for a distance of 23 ft. and worth 5 oz. 17 dwt., and an incline raise put up from the drift for 70 ft., averaged 3 oz. 14 dwt. per ton. The managers stated they could not yet estimate what quantity of rich ore this will yield, but these unexpected finds upset any calculations as to ore reserves.

The South Australian Minister for Mines has received the following report from Mr. H. L. Y. Brown (the Government Geologist) respecting the discovery in South Australia of the very rare and extremely valuable mineral, carnotite: "I have just received from Mr. A. Smith some specimens of a mineral which has been analyzed by Mr. Chapman at the School of Mines, and determined by him as carnotite. It comes from a lode located on a lease held by Mr. Smith in the Olary district. The importance of this discovery centres in the fact that pitchblende oxide of uranium is the mineral from which the rare substance of radium is obtained. The owner of the lease has arranged to provide bulk samples of the ore for examination and analysis. I propose to visit the locality at an early date."

A sign of the times is to be found in the proceedings at the general meeting, this week, of the West Australian Goldfields Ltd. In recommending a forward policy for the Company, the chairman called on his colleague, Mr. Oliver Wethered, to give an account of a tin property in Cornwall which had been offered them. Mr. Wethered, after the inevitable reference to Dolcoath, remarked that the awakened interest being taken in Cornish mining was no doubt due to the big rise in tin, consequent on the great demand for that metal and the reduction in visible supplies by nearly two-thirds in the course of eight years. The authorities, although differing in their views as to whether the present high prices will be maintained, were at one in believing that a much higher average of price may be expected for a long time to come. Another factor was the introduction of electrical power, which will enable old shafts to be equipped with pumps of far greater capacity than was possible in the old days, but which pumps take a mere fraction of the space occupied by the old Cornish pumps. Then, too, the miners will be rapidly lowered and raised to and from their work by use of high-speed winding engines, instead of coming to the surface after exhausting climbing or by means of the old man-engine. The use of rock-drills, high explosives, and electrically-driven fans for ventilation, etc., will also greatly facilitate the reopening and successful working of the mines. The capitalization of any company should be on a conservative basis, and the royalties must be on a reasonable scale. It is due to the landlords to say that they are showing every disposition to arrange leases on that basis. With such conditions and the modern appliances, and the guidance of those widely experienced in Cornish mining, Mr. Wethered thought they might look forward to a good outcome of investments so near home, and where directors can give personal supervision by frequent visits to the properties. Some eight weeks ago, when in Cornwall, he was asked to visit a property which had been taken up by five working miners from South Africa, who had associated with themselves other miners, and between them they had put up 25 shares of £75 each, and opened up a good deal of ore and proved that they had a nice little mine, which, worked with adequate capital, could be made dividend-paying. This property they proposed to take in hand for the Company and it would not involve any large cash payment.

A favorable report for the year to December 31, 1905, is issued by the Briseis Tin Mines Ltd. (Tasmania). It states that, as was anticipated in the last annual report, the mine entered on the "producing stage" during the year, and the output steadily increased month by month until it reached 84 tons 1 cwt. from Briseis, and 30 tons 12 cwt. from New Brothers Home No. 1, or a total of 114 tons 13 cwt. in November. The December return was equally good, but on account of the Christmas holidays did not represent a full month's work. No difficulty has been found in keeping the overburden-faces sufficiently far ahead of the drift-faces, to prevent any possibility of a recurrence of the old conditions, and at the end of the year all the workings were in excellent order. The total output of black tin for the year from both properties was 971 tons, which produced 712 tons of metallic tin. Deducting 42 per cent of the No. 1 Company's tin (the proportion payable to them under the agreement), the total output of metallic tin belonging to the Company was 642 tons, which realized net £96,326.14.10. The average net price obtained during the year was thus £149 per ton. The net trading profit for the year, after paying all expenses, and writing £7,014.16.6 (10 per cent) off the cost of the water-races, amounted to £57,826.5.6. Since closing the accounts to December 31 last the Company has paid two dividends of 9d. each, on 600,000 shares of £1 each. The following particulars are taken from the report of Lake & Currie, the Company's engineers:

	Briseis.	No. 1	1905. Total.	1904. Total.
Overburden removed, cubic yards	455,500	96,048	551,548	755,424
Drift sluiced, cubic yards	281,950	199,400	481,350	173,440
Output black tin, tons	744.42	226.58	971	424.8
Output metallic tin, tons	546.4	165.9	712.3	311.26
Briseis Co.'s proportion of total output	—	—	642.62	311,26
Metallic tin sold	—	—	643.07	312.5
Average net price per ton	—	—	£149.6	£126.45
Total net proceeds	—	—	£96,326.7	£39,520.1
Rainfall at the mine, inches	—	—	49.78	48.96
Water available, average sluice-heads daily	—	—	148	166

The average cost of removing overburden during 1905 was reduced to 6d. per cu. yd. as compared with 6.21d. during 1904. A substantial reduction was also effected in the cost of winning tin. The average cost of producing black tin from the Briseis property, dressed and bagged at the mine sheds, was £9.45 per ton, equivalent to £12.11.3 per ton of metal, as compared with £11.19.5 and £16.7.4 respectively during 1904. To the above charges on metallic tin must be added £8.1.6 per ton for cartage, smelting, freight to London, and general expenses, making the total cost per ton of metal sold £20.12.9 per ton. Insurance and realization charges are not included in this item, as these amounts depend on the gross price obtained per ton. These figures include all expenditure except Melbourne, Hobart and London administration. As on former occasions, nothing has been charged on account of overburden removed, as it is impossible to allocate the proper proportion of overburden to each ton of metal won. The cost of this last year was estimated at from £8 to £12 per ton of metal produced, and this sum was not exceeded. An allowance of from £7½ to £8½ will be sufficient in the future, which will enable Briseis tin to be placed on the market at a total

cost not exceeding £30 per ton, including all charges except Melbourne, and London administration.

Stratton's Independence shares have slightly recovered from the shock administered by the cable noticed in my correspondence of last week. The manager reports by letter that the 200-ft. level in the Washington ground (granite area) is showing up well, and looks so promising that he is driving the 300-ft. level from the No. 1 shaft south to get under the orebody, also that the sampling of the dump now nearly completed will show an average value of a little better than three dollars per ton.

A somewhat belated cable from Dolores Mines Company announces the crushing for April month as 692 tons; total receipts $36,500; expenses $16,000; profit for the month $20,500.

Oroville Dredging Ltd. has declared a third dividend of 12½ cents per share payable on June 30. The annual meeting of the stockholders is to be held at Portland, Maine, on June 20.

TORONTO, June 15.

A large party of capitalists and mining brokers, under the direction of E. P. Earle of New York and his associates of the Nipissing Mining Co., visited Cobalt on June 9. Among the number were Wallace Nesbitt, H. F. Wyatt, F. T. Osler, Victor Cawthra, J. E. Osborne, Duncan Coulson, David Faskin, James Hawes and Arthur Hawkes, all of Toronto; J. J. Pangman, secretary of the Montreal Stock Exchange; W. Earle Hidden, a well-known metallurgist; Wm. Starr Bullock, Henry E. Woodworth and J. H. Cody, from New York; Harold S. Sims and W. F. Bartholomew from Boston. Their time was largely spent in a close examination of the veins now being worked at the Nipissing mine, where lunch was provided by the superintendent, Mr. Linney, each guest being presented with a silver nugget as a souvenir. The personal inspection of the wealth of Cobalt camp by so many leading financiers is regarded as an important step toward inspiring the public with confidence in Cobalt stocks, of which many brokers have hitherto been shy.—— Another rich find has been made on Lot 1, Concession 3, of Coleman township in the extreme southeastern section of Cobalt camp by Andrew Devine. The claim has been passed by the inspector, who declares the vein to be one of the best he has seen. The mine has been acquired by the Beaver Silver Mining Co., the prospector retaining a three-eighths interest.—— At Gillies Depot, five miles to the southwest of Cobalt town, W. H. Dickson has struck some promising cobalt-silver veins. The formation in this neighborhood is reported to be the same as that around Kerr lake.—— A nugget of almost pure silver has been found in working vein No. 26 at the Nipissing mines, quite near the surface. It weighs at least 100 lb.—— Edward Clark, manager of the Montreal Navigation Co., which is doing an extensive business in taking prospectors up the Montreal river, confirms the stories of rich finds of pure silver in that direction. At least two genuine discoveries have been made at Portage bay.—— Active prospecting is going on in the Temagami forest reserve, although the Government endeavors to discourage it, fearing the destruction of the timber by fire. Major Magee and W. R. Moore, of Ottawa, have located two pure cobalt veins, over two inches wide and also a nickel proposition on Kokoko lake. A gold discovery by an Indian is also reported. John Armstrong, formerly of Montana, is among those prospecting in the reserve.—— The Town Site Mining Co. has obtained from the Temiskaming and Northern Ontario Railway Commission a 999-year lease of the southwest 37 acres of the Cobalt townsite, which is known to be mineral land. It paid a cash bonus of $40,000 and in addition, agrees to give 25% of the gross value of every ton of ore, which has a value up to $1,000, and 50% on all ore worth over $1,000 per ton.—— A movement is on foot for the organization of a syndicate to acquire the mining rights to a large number of the remaining Cobalt townsite lots.—— The stock of the Trethewey Silver-Cobalt mine is being placed on the market. It is capitalized at $1,000,000 and the first issue of stock amounting to $300,000 is being offered at par.

In the House of Commons at Ottawa on June 12, Dr. Thompson, representative of the Yukon Territory, presented the claims of his constituents for a greater measure of self-government. He said he had the authority of experienced mining men for the opinion that more gold would be produced in the future than in the past. There were miles of auriferous gravel which capital would develop. Capital was coming in. The Guggenheim people were spending $2,000,000 on hydraulic and other machinery, and English capitalists were building a railway from Dawson into the gold district. In the southern part of the district, a quartz camp was being established. The Government should help in the way of securing water; an aqueduct was required to bring water to the gold-bearing deposits and provide means for their being worked. He presented figures to show that this would be a paying proposition.

TORONTO, June 11.

The army of prospectors in the Cobalt mining area and adjacent region has been largely re-inforced of late by the numerous college students and graduates, set free by the college commencements. The wonderful success of the three School of Practical Science men, Messrs. Blair, Kerr, and Glendinning, of the famous University mine, has had a widespread influence in directing the attention of college men to the opportunities offered by the mineral fields of northern Ontario.

Many new discoveries both in the Cobalt district and farther afield are reported, but it is not safe to accept all the reports which obtain publication at their face value. The most important, which is confirmed by Mining Inspector Mickle, who was in the immediate neighborhood at the time, was the finding of a vein of smaltite and calcite rich in silver ore on the property of the Temiscamingue Mining Co., Lot 1, Concession 3, of Coleman township. This extends the known silver area a considerable distance to the southeast. A find is also reported on Lot 6, Concession 3, Bucke township, three or four miles north of Cobalt, and about a mile north of the present mining operations. Prospectors up the Montreal river report valuable discoveries, but nothing definite as to happenings in that direction has come to hand.

Work on the smelter of the Cobalt Refining Co., at Hamilton, Ontario, is progressing rapidly and it is expected to be ready for operation in a couple of weeks. Nearly all the Cobalt producing mines will ship their ore to Hamilton for treatment. Several projects for the establishment of local smelters are being advanced, but the Hamilton enterprise has secured the start and seems most in favor with mining men. It is pointed out that the work can be more economically done at such a frontier point, as it will cost considerably less to ship the ore there than to bring fuel to Cobalt. In the meantime ore is being stored by most of the mines until the smelter is ready for it.

An incident of importance in relation to the question of the permanency of the Cobalt camp has recently transpired in the recovery of a lost vein in the Trethewey mine. Some time since a rich vein in the western working of the mine was lost and it was conjectured to have petered out against the adjoining greenstone or Keewatin formation. The matter was kept quiet, because it tended to indicate the shallowness of the deposit. The lost vein, however, was found to have been faulted and it has been struck again at a distance of eight feet, yielding as rich as ever. Prospecting work carried on by the Peterson Lake Mining Co. has resulted in the discovery of a promising vein of niccolite. A large number of prospectors have been at work at the Foster mine for some time and 20 pronounced veins have been located. Driving at the old shaft on the 50-ft. level has resulted in obtaining some very rich ore, four carloads of which are awaiting shipment. It is predicted that the returns from this consignment will create a sensation. A new vein five inches wide carrying rich ore has been struck at the McKinley & Darragh mine. The locality where it was found was prospected some time ago and regarded as non-productive. Preparations are being made for active development work at the Columbus mine and the contract has been let for the sinking of a double-compartment shaft 110 ft. Shafts are also being sunk at the Savage and Silver Bar mines.

The preliminary report on the experiments recently made in the electric smelting of Canadian iron ores by Eugene Haanel, Dominion Superintendent of Mines, has just been issued by the Canadian Department of the Interior. The object of these experiments was to establish the feasibility of the process as applied to Canadian conditions, the most important points to be settled being whether magnetite, the leading Canadian iron ore, could be smelted by electricity as easily as hematite; whether ores comparatively high in sulphur but containing no manganese, could be made into marketable pig iron; and whether charcoal could be substituted for coke as a reducing agent. The last point was considered specially important, charcoal and peat-coke being domestic products, while coal-coke has to be imported into the provinces of Ontario and Quebec. The report goes fully into detail with regard to some of the experiments of special interest and importance, giving analyses of the raw material and output. It is claimed that notwithstanding some defects in the construction of the furnace, rendering it impossible to provide for utilizing the calorific energy of the carbon monoxide resulting from the reduction of the ore, and causing unnecessary combustion of charcoal, the experiments have solved satisfactorily all the points to be decided. There was not the anticipated difficulty in the smelting of magnetite by reason of its conductivity, and charcoal, when crushed to pass a three-quarter inch ring, could be used as a reducing agent without being briquetted with the ore. The report expresses the opinion that probably the largest unit which can be constructed on the model of the experimental furnace, will not exceed 1,500-h.p. The construction will require to be modified to provide for the collection and utilization of the carbon monoxide and also to protect the charcoal charge from combustion on the top of the furnace. These changes and the fact of the greater capacity insuring less loss of heat from radiation will materially increase the output beyond that ascertained by the experimental furnace. The experiments indicated that under normal conditions about 11.5 tons of pig iron were produced by an expenditure of 1,000 e. h. p. days, so that for the purpose of calculating the cost of production it is assumed that, with a properly constructed furnace, the output of a similar expenditure of power would be 12 tons. On account of the value of the product the smelting of roasted nickel pyrrhotite, as carried out by the experimental plant, admits of commercial application without further modification of the furnace than increase of its capacity. The number of runs made during the demonstrations was about 150, and the total output about 55 tons of pig iron. Eight different classes of iron ore, principally magnetite, were used. On the authority of P. Heroult, the report estimates the cost of a 10,000-h.p. plant with a capacity of 120 tons of pig iron per 24-hr. day, at $700,000. The cost of production per ton of pig iron is calculated at $10.69. In addition to the results mentioned, the experiments have shown that ores of high sulphur content not containing manganese can be made into pig iron containing only a few thousandths of one per cent of sulphur; that the silicon content can be varied as required for the class of pig iron to be produced, and that titaniferous ores up to perhaps five per cent titanic acid can be successfully treated by electric process.

BUTTE, June 16.

The net earnings of all the Butte copper mining companies for the year ending June 1 amounted to $17,336,650.56 against $9,939,969 the preceding year. The net earnings of the various companies were as follows:

Companies.	1906.	1905.
Boston & Montana	$6,158,109 56	$5,855,620
Anaconda	5,753,265 42	2,259,694
Butte & Boston	1,075,892 79	178,713
Parrot	277,015 36	328,107
Trenton	541,528 54	70,110
Red Metal (United Copper)	1,035,206 03	606,953
Original	647,624 10	349,387
North Butte	1,848,008 76	291,385
Total	$17,336,650 56	$9,939,969

The Parrot Co. alone showed a decrease. The Washoe Co., of the Amalgamated, invested all of its earnings in smelter improvements, amounting to $532,883.81. Abstracts of the reports of the different companies, which here follow, give some interesting details of operations, cost of mining and reduction per ton of ore, gross yield per ton and other information.

Boston & Montana Mining Co.—Mines operated: Mountain View, Pennsylvania, Leonard, West Colusa, East Colusa, Greenleaf and Badger State. Tons of ore extracted, 1,209,805; gross yield per ton, $12.82; cost per ton to extract and mine, $3.46; place of reduction, Great Falls, distance 172 miles; total cost of transportation, $1,129,547.14; cost of reduction per ton, $2.45; expended for labor, $3,886,744.94; expended for machinery, $63,254,429.73; marketing charges, including refining, freight, selling charges, etc., $1,081,000.68; gross proceeds, $15,509,832.05; total expenditures, $9,351,722.49; net proceeds, $6,158,109.56.

Anaconda Co.—Mines operated: Anaconda, Never Sweat, St. Lawrence, Mountain Consolidated, High Ore, Bell, Gallatin and J. I. C. Tons of ore extracted, 1,521,310; gross yield per ton, $10.92; cost per ton for extraction, $3.63; place of reduction, Anaconda, 27 miles; total cost of transportation, $231,999.25; cost per ton for reduction, $2.27; paid for labor, $4,394,103.02; expended for machinery and supplies, $4,088,224.88; marketing, etc., $1,645,943.94; gross proceeds, $16,613,137.01; total expenditures, $10,860,371.59; net proceeds, $5,753,265.42.

Butte & Boston Co.—Mines operated: East Gray Rock, Silver Bow, Blue Jay, Berkeley. Tons of ore extracted, 246,593; gross yield per ton, $11.44; cost per ton

for extraction, $3.51; total cost of extraction, $866,357.81; reduction at Anaconda; total cost of transportation of ore, $49,318.62; cost per ton of reduction, $2.06; total cost of reduction, $509,028.03; paid for labor, $869,647.02; paid for machinery and supplies, $505,738.82; marketing, refining, etc., $320,722.24; gross proceeds, $2,821,319.49; total expenditures, $1,745,426.70; net proceeds, $1,075,892.79.

Washoe Co.—Mines operated: Moonlight, Cambers and Clear Grit. Tons of ore extracted, 95,210; gross yield per ton, $12.05; cost per ton for mining, $4.33; reduction at Anaconda, cost per ton, $2.73; marketing, etc., $97,764.35; paid for improvements, $532,883.81; gross proceeds, $1,146,981.03; total expenditures, $1,322,702.25; expenditures in excess of receipts, $175,721.22.

Parrot Co.—Mines operated: Parrot, Bellona, Original and No. 6. Tons of ore extracted, 163,569; gross yield per ton, $8.54; cost per ton to mine, $3.65; place of reduction, Anaconda; total cost of transportation of ore, $29,442.42; cost of reduction per ton, $2.16; marketing, selling charges, etc., $141,281.75; gross proceeds, $1,397,406.82; total expenditures, $1,120,391.46; net proceeds, $277,015.36.

Trenton Co.—Mine operated: Gagnon. Tons of ore extracted, 168,770; gross yield per ton, $9.18; cost per ton for extraction, $2.92; reduction at Anaconda, total cost of transportation, $25,315.47; cost of reduction per ton, $2.09; marketing, selling charges, etc., $131,422.20; total expenditures, $1,007,570.89; net proceeds, $541,528.54.

North Butte Co.—Mines operated: Speculator group. Tons of ore extracted, 259,650; gross yield per ton $21.11; cost per ton for extraction, $4.47; reduction at Anaconda, total cost of ore transportation, $52,017.23; cost of reduction per ton, $4.84; paid for labor, $646,281.35; machinery and supplies, $514,484.86; improvements and investments in mines, $1,164,000; gross proceeds, $5,480,545.24; total expenditures, $3,632,531.48; net proceeds, $1,848,008.76.

Red Metal (Butte Coalition Co. from Feb. 1 to June 1.)—Mines operated: Rarus, Minnie Healey, Corra and Belmont. Tons of ore extracted, 149,101; gross yield per ton, $12.94; cost per ton for extraction, $3.94; place of reduction, Basin, Mont.; total cost of transportation, $89,460.60; cost per ton for reduction, $3.94; paid for labor, $547,005.97; expended for machinery and supplies, $628,151.20; marketing, etc., $223,651.50; gross proceeds, $1,929,568.17; total expenditures, $1,488,269.27; net proceeds, $441,298.90.

Montana Ore Purchasing Co. (now Red Metal, from June 1, 1905, to Feb. 1, 1906, eight months).—Mines operated: Rarus, Corra and Minnie Healey. Tons of ore extracted, 274,322; gross yield per ton, $8.83; cost per ton for extraction, $4.38; total cost of transportation, $69,129.14; cost per ton for reduction, $2.04; gross proceeds, $2,423,086.22; net proceeds, $593,907.13.

Original Co.—Mines operated: The Original and Stewart. Tons of ore extracted, 316,466; gross yield per ton, $8.61; cost per ton for mining, $3.47; total cost of transportation, $63,152.56; cost per ton for reduction, $2.90; paid for labor, $727,390.48; paid for supplies, $370,998.99; net proceeds, $647,624.10. Royalties received on other Clark properties, $866.34.

Alice Co.—Tons of ore extracted, 3,831; gross yield per ton, $8.23; cost per ton for extraction, $9.76; gross value, $31,524.81; loss in operations, $5,871.07.

Following is given in tabulated form a resume of the above:

COMPANIES	Gross yield per ton	Cost per ton for mining	Cost per ton for reduction
Boston & Montana	$12 82	$3 46	$2 45
Anaconda	10 92	3 63	2 27
Butte & Boston	11 44	3 51	2 06
Washoe	12 05	4 33	2 73
Parrot	8 54	3 65	2 16
Trenton	9 14	2 92	2 09
North Butte	21 11	4 47	4 84
Red Metal	12 94	3 94	3 94
Montana Ore Purchasing	8 83	4 38	2 04
Original	8 61	3 47	2 90
Alice	8 23	9 76	....

The engineers in the employ of the Amalgamated and Butte Coalition Co. have arrived at an agreement for a division of the disputed orebodies which for years were in litigation between the Amalgamated and United Copper Co., the latter the predecessor in interest of the Butte Coalition. The terms of settlement and division have not been made public, but have been taken to New York by B. B. Thayer, assistant to H. H. Rogers, president of the Amalgamated, and they will be laid before the directors of each company for approval. As soon as the boards formally pass on the reports, the various mines which have been closed by injunction for many years, will be reopened.

The Coalition Co. has already begun sinking a shaft on the Tramway, one of the mines that has been in litigation, and will sink it to 1,800 ft. The Parrot, also, has begun mining on one of the veins from which it was excluded by an injunction for a number of years.

The Raven Mining Co. has suspended operations. Its best mine, the Snoozer, was operated through the shaft of the Buffalo mine, owned by the Anaconda Co., but it had no lease on the shaft. Last week the Anaconda Co. closed the shaft to the Raven Co. and will use it in developing some of its own properties. The old hoisting building is being torn down to obviate the danger of fire, and it is stated by officials of the Raven that as soon as the work is completed the Anaconda Co. will hoist Raven ore under an arrangement that will be better for the Raven than the old one. The Raven does not own all of the Snoozer mine, the Butte Coalition owning an eighth, and under Montana laws, the owner of an interest can not operate a property without the consent of the co-owner, so that at any time the Coalition Co. can, if it wishes, completely stop operations in the Snoozer. In order to reach the Snoozer the company is working by means of a tunnel driven through the property of the Old Glory Co., and the latter has, for a long time, been threatening injunction suit.

It has been officially announced that the Washoe smelter at Anaconda is to be materially enlarged and that an expenditure of $600,000 for that purpose has been authorized. It is the purpose of the company to increase the plant so that its monthly output will be 20,000,000 lb. copper. The plans provide for a complete electrical installation in the concentrator plant and a partial electrical installation in the smelter power-house. In the latter plant the power required not generated by the waste-heat boilers, will be developed by electricity when the new system is completed. Eight roasters will be added and also another 112-ft. reverberatory furnace. A new blast furnace 87 ft. long will be put in, the largest ever constructed. Two stands of converters will be added in order to take care of the increased production of matte. Additional machinery will also be placed in all other departments of the plant. The enlargement of the Washoe is in addition to that which is to be done by the Amalgamated at its smelter at Great Falls, which is to be enlarged for a production of 10,000,000 lb. copper per month. All the ore for this enormous production at the two smelters will come from the mines of the Amalgamated Co. in Butte.

The Trenton Mining Co. is preparing to sink its shaft from the 1,900-ft. mark to 2,000 ft. The Gagnon mine, the company's only property, is now producing 600 tons of ore per day of a better quality than it had been producing in a long time.

SALT LAKE, June 18.

The Peck concentrating mill, built to treat the zinc ore of the Horn Silver mine, at Frisco, Beaver county, has been closed to undergo alterations and enlargement. The plant was built originally to treat from 300 to 400 tons daily, but has failed to do it. Results from a late run showed a satisfactory separation of zinc, the zinc concentrate running 50% and the lead concentrate from 45 to 55%. Shipments of ore are about to be made from the Indian Queen mine, near Newhouse, Beaver county. This property is said to be under option to James F. Burns, of Cripple Creek.

The Sacramento Gold Mining Co. of Mercur, Glen R. Bothwell and R. E. McCaughnahay, president and secretary, respectively, have filed answers in two actions for $231,000 damages and trespass brought by the Herschel Gold Mining Co. Defendants deny that the ore in question belonged to plaintiff as it was mined during the life of an agreement entered into in 1893 between the two companies, which specified what ore the defendant was entitled to, and that the ore taken out was not in excess of that amount and was extracted with the knowledge and consent of plaintiff.

The Daly-Judge Mining Co., operating at Park City, made a net profit on its May operations of approximately $55,000, while the expense was about $23,000. The company has enough money on hand to clear up all its indebtedness, which will be liquidated within the next ten days.——An important strike has been made in the New York Bonanza mine, at Park City, where an east drift on the 700 level has encountered a three-foot vein of high-grade silver-lead ore; it is said to be the best ore ever opened in the property.——Good progress is being made with the drift alongside the caved section of the Ontario drain-adit at Park City. Hard rock has been encountered, removing the necessity of timbers. The adit has been closed since March, 1904, which has greatly interfered with the development of orebodies of some of the principal mines of the district.——The labor troubles of the Daly-West Mining Co. are seemingly at an end, the company consenting to make it discretionary with the miners whether they use candles or the lamps, the introduction of which by the management caused the recent difficulty.

The management of the new smelters, now nearing completion at Garfield, on the south shore of the Great Salt lake, had some experience with labor troubles last week. A lot of Greeks quit work and attempted to take matters in their own hands by resorting to intimidation. Armed with clubs and stones they drove nearly every employee from the works, threatening to kill anyone who did not leave. The sheriff of Salt Lake county, with 50 armed deputies, arrested 26 of the leaders and 81 were deported, which put an end to the difficulty. Some of the mining companies of Bingham have had trouble with Greeks and some of them have concluded not to give employment to men of that nationality in the future.——The new sampling mills at the Garfield smelters will be ready for business some time next week. It is expected the blowing-in of the first furnaces will take place a few days later.

The Sunday mine, in American Fork canyon, which was a producer of consequence 30 years ago, is to resume operations. The property is owned by Chicago and Duluth people who have organized the Sunday Mining Co. Charles Crane, of Chicago, is manager and will take charge of the work, making his headquarters at American Fork.

The ore and bullion settlements reported last week by Salt Lake banks aggregated $450,600.

Ore shipments from the Tintic district last week aggregated 156 carloads, the shippers and amounts being: Ajax, 2; Beck Tunnel, 5; Black Jack, 12; Bullion-Beck, 7; Carisa, 8; Centennial-Eureka, 33; Dragon Iron, 16; Eagle & Blue Bell, 5; Eureka Hill, 2; Gemini, 13; Godiva (concentrate) 1; Grand Central, 6; Mammoth, 18; May Day, 3; Ridge & Valley, 3; Scranton, 3; Swansea, 3; Uncle Sam, 4; Victoria, 4; Yankee Consolidated, 6; other mines, 1.——The Scranton zinc mine in North Tintic is working 35 men and shipping 40 tons of ore daily to Colorado smelters.——The Anadale fraction mining claim, adjoining the Centennial-Eureka mine of Tintic, has been sold to Elmer Jones of Salt Lake and associates, it is said, for $25,000.——The Mammoth Mining Co. continues development below the 2,200 level with satisfactory results, and the management reports that the mine has not looked so well in years as it does now. Production has been handicapped by a scarcity of water.——Tintic operators are working for a low tariff on ore to the Salt Lake smelters. The transportation companies have been asked to make a $1 per ton rate on ore having a net value of $10 or less per ton; $1.50 per ton on ore having a net value of $20 per ton or under, and $2 per ton on ore netting above $20. At present the minimum rate is $1.50 per ton on ore not exceeding $15 per ton and $2.50 on all ore going above $15 per ton. The operators insist that they should be granted these concessions, which would enable them to market, profitably, large amounts of low-grade ore which now has little commercial value.——The management of the Beck Tunnel Consolidated of Tintic district has established a minimum wage scale of $3 per day.

The South Columbus Mining Co., operating at Alta, has resumed development and is continuing its tunnel.——The Pioneer Mining Co., at Alta, is pushing work in an adit, now in over 500 ft., and which will tap known orebodies 500 ft. further in.

The Buckhorn mine, at Ophir, which adjoins the Ophir Hill property of W. A. Clark, is now controlled by Duluth parties who have organized the Cliff Mining Co. A. D. Johnson, of Duluth, is president; W. F. Snyder of Salt Lake, vice-president; A. L. Kern, of Milwaukee, treasurer; R. M. Atwood, of Helena, Montana, general manager. The property is to be equipped with new machinery and an aerial tramway. Some large orebodies have been developed in this property.

The directors of the Carbonate Hill Mining Co., operating in Morgan county, have authorized the equipment of the mine with an air compressor, power drills, and aerial tramway. M. A. Daugherty of Salt Lake is manager.

Much interest is being taken in the mining districts of the Deep Creek country in the west line of the State by a number of men who have been prominent in the development of Goldfield, Nevada. A great deal of bonding of properties is going on and indications are favorable for much activity in that section later in the year.

The Bingham Mines Co. has been organized to operate in Bingham. It has acquired property in the upper portion of the camp near the Boston Consolidated and United States mines. John Dearn is president; Charles W. Whitney, vice-president; Frank Knox, treasurer, and P. B. Locker, secretary, all of Salt Lake. Its territory embraces 250 acres.

MINING SUMMARY

ARIZONA.

COCHISE COUNTY.

A bond on the Copperopolis mine at Paradise is held by E. F. Sweeney of Paradise and Geo. H. Crosby of Duluth, Minn. Three payments have been made, the fourth and last being due in August. Present owners of the Copperopolis are: G. B. Richardson, M. R. LaRue and Geo. H. Crosby, the last mentioned having purchased the interest of P. G. Carney. The group consists of eight claims and lies near the center of the district. The mineralized zone is 60 ft. wide on the west, to 600 ft. on the east, extending through three claims. The iron out-crop is visible here and there throughout the entire length. At intervals sulphide of copper is discernible in rock at the surface and one can dig up with the hand or detach with a hammer, good copper ore which is found mostly in limestone, though sometimes also in porphyry. Ore is also found with green, brown and yellow garnets and hematite is present almost everywhere in large quantities. Samples run from 8 to 20% copper. Lead is also found in most of the workings.—— The best showings are on the Blue Bell and New Year claims. On the Blue Bell there are several adits from which good ore was taken. On the Copperopolis claim, which adjoins the Blue Bell, a shaft makes a good showing.

MARICOPA COUNTY.

A carload of rich ore from the Fortuna mine, 16 miles northeast of Phoenix, will be sent to the Humboldt smelter. It is said it will average $2,000 gold per ton. William Hoover, who discovered it, secured a lease on the mine and has been at work, though not constantly, for three months in getting it out and he has done all the work alone.

MOHAVE COUNTY.

Howard & Littlefield are making a run on ore from the Boulevard mine 15 miles north of Gold Roads, crushing it in the Pyramid Mining Co.'s mill, six miles from the mine. The Boulevard rock is free-milling gold ore of high grade.

YAVAPAI COUNTY.

The company, represented by H. J. Beemer, that holds a bond on the Storm Cloud claims on Mount Union, 15 miles southeast of Prescott, made a payment of $27,000 on the purchase price last week. There are 15 claims in the group, all of them showing well-mineralized veins. There was a good deal of development done when the Beemer people took hold of them, and now an adit is being driven and three shifts are putting down a shaft.—— The Senator Co. is driving an adit under Mount Union, now in 3,000 ft., and has cut several veins of good ore, the best being that of the Ten Spot.—— For several weeks pumps have been unwatering the Octave mine at Antelope Hill. Shaft No. 2, on that property, has been unwatered and 80 ft. of sinking done since the water was taken out. The result of the work is satisfactory. This shaft is now down 1,640 ft. At 1,500 ft. there was a squeeze, but the workings are now in a strong vein. The force of 20 men will be doubled inside of 30 days.

CALIFORNIA.

BUTTE COUNTY.

Los Angeles capitalists are reported to have bought the A. F. Hornung place near old Diamond, comprising 120 acres, and intend to mine it with steam shovels, the machine working on the ground instead of in water. Another Los Angeles company has bought 60 acres at Rich Bar on Butte creek and will also install a steam shovel and sluices.—— A third company has taken the R. F. Ferguson property of 150 acres across the creek from the Rich Bar and will work it in a similar manner.

EL DORADO COUNTY.

At the Mount Pleasant mine, at Grizzly Flat, the north shaft is being sunk from the 1,000 to the 1,100-ft. level. Three eight-hour shifts are working. At the 1,100-ft. level cross-cuts will be run to the ore-shoots——A number of men are making an examination of the Georgia Slide mines. So far the prospects are favorable.

MONO COUNTY.

It is reported at Bodie that the Standard Consolidated Co. is planning to enlarge its cyanide plant and also the power plant at Green creek, the object being the more economical handling of the tailing accumulated.

NEVADA COUNTY.

It is reported that the Norambagua mine on Deadmans Flat, near Nevada City, is to be sold. An examination, in the interest of southern California men, is being made. Years ago this mine produced rich ore, but lack of capital finally led to a cessation of work. Some months ago operations were resumed, the long adit being cleaned out and retimbered.

The New York-Grass Valley mine, near Grass Valley, has purchased land adjoining its mill, on which to erect a large cyanide plant now under construction in San Francisco. At the Central Consolidated, the owners, failing to receive the electric pump from the East, have put in a bailing-tank, which is steadily lowering the water. Development will be carried on in the old workings on a large scale.

It is reported from the Zeibright mine, in Little Bear valley, that a rich strike had been made in the upper adit, which had been running through barren rock for the last 130 feet.

PLACER COUNTY.

The Valley View copper mine, near Danetown, is again to be unwatered for the purpose of examination by prospective purchasers.

SAN BERNARDINO COUNTY.

A rich strike of lead-silver ore is reported seven miles west of Daggett, in an old mine discovered in the early days of Calico. There is very little lead in Calico district, but the hills lying south of the Calico range and extending westerly from Daggett contain numerous deposits of lead-silver ore. Ore from the new strike is to be shipped.——The Paradise Mining & Milling Co. will soon build a mill at its mine near Paradise Springs, 15 miles north of Daggett. The Poliets property will be worked by this company.——It is reported that Samuel Newhouse has bought the New York mine on the northeast end of New York mountains, three miles west of Manvel. This mine is the oldest in that part of the San Bernardino copper belt. It has been developed and some rich ore found.——New York mountain is dotted with camps, and development of copper veins is active.

SHASTA COUNTY.

Machinery has arrived at Redding for the Washington mine, near French Gulch. The mine is to be equipped with machine drills, gasoline engine and compressor. Walter Van Matre is superintendent. The Washington was a large producer in years gone by. Charles Webb, a lessee, struck it rich a few months ago, cleaning up several thousand dollars. When this lease expired, three or four months since, he could not get a renewal. Rich ore was left in sight when Webb quit. To get at the orebody more advantageously an adit was run 200 ft. lower, which will be driven 500 ft. before the vein is struck.

The Brunswick mine, near French Gulch, has been sold to H. D. Lacy of New York, who paid Francisco B. Rossi $39,000 and gave a mortgage on the mine for the payment of the $20,000 additional within six months. A payment of $1000 was made several months ago. The Brunswick mine was successfully worked 20 years ago. It was supposed to be worked out and had lain idle for several years before Mr. Rossi took hold of it. The new owner will install a stamp-mill on Willow creek and another adit will be run to tap the vein 300 ft. lower than the present workings, for which surveys are now being made. It will be 1,200 ft. long. Mr. Rossi will be retained as superintendent.

The **Mammoth Copper Co.** has made an important change in supplying water to the smelter. Heretofore, two centrifugal pumps, each of 500 gal. capacity per minute, have raised the water from Backbone creek to tanks above the smelter. Water will now be taken from the Butters' ditch, which passes above the smelter. The Butters' water system is nearly completed. When finished the total cost will approach $40,000.

SIERRA COUNTY.

(Special Correspondence).—The Sierra Buttes Co. has its 20 and 40-stamp mills running steadily.—— The Sierra Alta, or Keystone, has a large force and the mill is running full time.—— The San Jose Co., that has Jack Hayes' property bonded, has recently struck a large body of ore showing gold. They claim to have enough in sight to justify a mill and will erect one as soon as they can get it on the ground.—— The Marguerite Co. has installed large pumps and expects to have the shaft clear of water soon.—— The Sovereign opened up a large body of free-milling ore the past winter and are going to make a test run in the Primrose mill.——The Empire Co., in Gold Valley, is running 25-stamps on good ore.——John Buckingham is erecting a 5-stamp mill on his mine in Jim Crow canyon. ——C. J. York, owner of the Downieville foundry, is building a 5-stamp mill for custom work, a commendable and necessary enterprise, which will probably be the means of developing a number of good prospects in this vicinity.——There is a new district being opened in the eastern part of this county near Loyalton, where a number of Truckee and Reno people have recently made locations.——S. L. Jones, A. C. Hamilton and W. S. Hoskins have recently been making an examination of the Tightner mine to determine what is necessary in the way of machinery to continue future development.——The California Debris Commission has granted the Alleghany Mining Co. a permit to construct a restraining dam on its property near the town of Alleghany.——The South Fork Co., at Forest, has its main adit in 4,000 ft. and thinks it is in the west rim of the channel and expects to strike gravel soon.——S. H. Shaw, while prospecting for gravel in Rattlesnake ravine, was killed by the accidental explosion of nitro powder on May 29.—— The Telegraph mine has sunk an incline in good gravel and is preparing to run gangways and breast out. It has also installed a Cornish pump in its quartz shaft and will resume sinking.——The Golden Scepter has closed down temporarily and the Herkimer expects to strike pay gravel any day.

Downieville, June 14.

SISKIYOU COUNTY.

An electric line is being built to the Morrison & Carlock mine in Quartz valley for running the mill, hoists and other machinery. This company now employs 40 men.——The Golden Eagle quartz mine, at Indian creek, operated by A. C. Brokaw, is yielding good returns, working day and night. The New York mine will probably be started up again shortly, as the squabble among directors and stockholders has been settled. ——Improvements are being made in the Mono mine on Punch creek, Humbug district. The equipment comprises a 10-stamp mill run by electricity, and a cyanide plant.——The Brooks mine, on the east fork of Eagle creek near Gilta, purchased by P. L. Young of Orleans Bar, is now showing up well, a vein having been cut ranging from six to ten feet that assays well.——The mill at the Highland mine at China Basin is running on rich rock. The mine has produced nearly $200,000, and has hardly left the grass roots. A lower cross-cut adit is now being driven.——Work at the Advance mine is under the management of Chas. Ritz. The orebody is said to be showing up well in the lower level. Several hundred tons of ore, now on the dump, are being transferred to the mill, which is running under the management of Naylor and Martin. Louis Cory is looking after the interests of the original owners of the property.

TRINITY COUNTY.

The June rains this year have made a marked difference in the placer mining season. All the mines in the vicinity of Weaverville are running full blast. At the Testy mine the water has kept up well and at the Hupp mine, which is being opened in a new channel, the bank is increasing in height daily. The gravel is free and easy to wash. In addition to the mine work, a new public road was constructed on East Weaver creek which has been recently improved by the building of an easy grade from the creek to Harvey flat. The total rainfall to date is 41.70 in., as against the total of 41.31 in. for the entire year ending June 30, 1905.

YUBA COUNTY.

The Bessie quartz claim is the newest mine in Brown's valley, twelve miles from Marysville. Byron Burris, the owner, has sunk a shaft 100 ft. and in a drift at that point, has broken into a vein that shows gold. The find is supposed to be a southerly extension of the Old Flag. Eight men are at work in the mine.

COLORADO.

LAKE COUNTY.

A sensational discovery of rich float quartz assaying 40 oz. gold per ton, is reported made on the Tennessee fork of the Arkansas river, seven miles west of Leadville. It is thought by many that the discovery means the opening of a new mining district that will rival the Cripple Creek section in size and value.——A discovery of rich gold ore is reported in the Ibex, or Little Johnny, at Leadville, by Robert Walker and Logan Hawkins, lessees. While working in one of the stopes they encountered a pocket of ore from which, in a few hours, they took out and sacked 110 lb. of ore that returned $25,000. The mass of gold mixed with white waste was five feet high, two feet wide and an inch thick. The Ibex company will receive 65% of this gold and the lessees 35%. Another find of 57 lb. of ore was recently made which yielded $13,680. This gold was sold to eastern banks for specimens and brought more than $20 per ounce.

OURAY COUNTY.

At the Camp Bird, work is being pushed in the replacing of the mill destroyed last spring by a snowslide. Nearly 100 men are working upon the excavations and rough work, while 30 carpenters are engaged in framing timbers. The stamps and other machinery have been purchased, mostly in Denver, and they will be installed as soon as the buildings are complete, which it is thought will be by September. Fourteen men are at work at the mine doing development work, and no

more can be employed until the mill is finished and the tramway repaired. When mining begins again the waste rock will be trammed down and used for the purpose of constructing a break and guard against future snowslides. At miners' union headquarters in Ouray a call was received last week from mines in the district for single and double-hand hammers-men; a class of miners that seems to be growing scarce in the San Juan country since the introduction of machines. Machine men and helpers now command the highest wages in the mines, $4 and $4.50 for eight-hour shifts.——One of the most extensive mining enterprises to be worked in the San Juan country this season is the Treasury adit and the combination of other interests which has been made with it. The adit will be run in the direction of the Tomboy mines. This means employment of 1,000 men in the Red Mountain and Ironton districts. The ore will go out through Silverton, but the men and supplies will be largely drawn from Ouray.——Interesting complications will arise out of the adjustment of the loss on the Camp Bird mill in Ouray district, which was wrecked by a snowslide several days before the fire. It has been found that two warehouses containing the mill-supplies and other material higher up on the mountainside, had been swept down by the snowslide and were dumped into the mill, where the debris afterward was destroyed by fire. As the property was insured in the other location, an interesting point in the adjustment is expected. The insurance companies are reported to have offered to compromise the loss on gold in solution at $149,000, the total insurance being $200,000.

SAN MIGUEL COUNTY.

The Silver Bell mine at Ophir Loop, under lease to H. H. Hutton and Frank Trumble, is reported as successful this season, since getting the mill in operation. About 30 men are on the pay-roll and a lot of good ore is being produced. The ore is sorted and a good part of it shipped, the rest being treated at the Bell mill, 10 stamps of which are constantly in use. The proposition is not operated on a large scale, but it makes dividends for the lessees. Mr. Hutton has charge of the mill and Mr. Trumble is mine boss.—— It is reported that damage had been done the Keystone placer buildings by the high water in San Miguel river. The channel, which was formerly 18 ft. wide, became a torrent fully 150 ft. in width, carrying down boulders weighing tons. Wm. Leslie, the watchman for the company, was awakened by a crash and looking out found that the cook house, compressor house, blacksmith shop and stable had disappeared and the place upon which they stood was a swiftly moving stream. The only building remaining being the old boarding house which stands up 50 ft. from the river bed, the balance of the ground being washed out during the night.

TELLER COUNTY.

The Elkton Co., at Cripple Creek, has increased its output to one car per day, the ore being obtained in its sixth, seventh and eighth levels. Cross-cutting is being pushed on the fifth level for the orebody cut in the third.——Frank Caley has sunk the shaft in his Arapahoe lease on the Jerry Johnson, on Ironclad hill, to a depth of 600 ft., and has found mica schist in a cross-cut. This is believed to be an alteration of the granite, and it is expected ore will soon be found.—— Machinery has arrived at the shaft on the northeast corner of the Mabel M. ground on Raven hill. The work will be done by Murray, Ragland & Husted, lessees in the camp, and 630 ft., or water level, in that section of the camp will be reached before doing level work. It is proposed to cut the Requa-Savage orebody which enters the Mabel M. ground at 400 ft., and is described as being six feet wide and rich.——The second mine of the district today is the Granite, with two deep shafts, on Battle mountain. The mine sent out, during May, 120 cars of ore, and is outputting four cars per day. Most of this production comes from the hill shaft, which is 1,000 ft. deep. About 75 tons are being hoisted through this shaft, the remainder coming from the Gold Coin shaft of the Granite Co. at Victor. About 45 tons per day are being raised there, mined from the 700 to 1,000-ft. levels. This shaft is filled with water from the 1,200 to the 1,000-ft. levels, and no efforts will be made to drain it until it is relieved by the new deep drainage adit. There are several sets of lessees working in the Granite property, in either shaft, the grade of ore secured by them averaging about two ounces.——The Granite is in charge of Allen T. Gunnell, Jr.——Lessee Boynton is making regular shipments from his lease on the dump of the Granite mine. Four cars were shipped during May, and a corresponding rate of output is being made during June.

(Special Correspondence).—The Darnell lease on the little May, on Beacon Hill, is shipping three cars of ore per month, which averages $30 per ton. The shaft is down 230 ft. and is equipped with electric hoist. This property is part of the El Paso holdings. While the lessees strike some rich streaks at times, the lease is not considered high grade.—— The El Paso mine, on Beacon Hill, encountered a large flow of water below the present drainage adit some months ago, and being unable to handle it with their big pumps, have abandoned work below the adit level. They have enough ground above it to keep them working for two years. —— The new drainage adit does not materialize as rapidly as was hoped. It is believed by many in the district that the necessary funds will be raised and that the adit will be driven. Unless this adit becomes a reality it will not be many years before several of the large producers in the district will be forced to close down on account of water.—— The Henry Adney mine, as well as the Union Leasing Co., is doing considerable work in the vicinity of the El Paso mine.—— R. S. Prettyman, manager, and J. B. Truitt, superintendent of the Iron Clad Mill Co., are operating the mill of the old Homestake Co. on Iron Clad hill, and claim to be making a good saving. The ore averages $2.36 per ton. The mining expense is about 32c. per ton, and mill treatment, including power and water, 70c. per ton. J. W. Price has taken a lease on the Montrose, adjoining the Forest Queen, on Iron Clad hill, and has started a shaft.—— Geo. D. Kilborn, general manager of the Isabella Mines Co., is authority for the statement that his company will erect a large cyanide mill to treat the dumps which contain several hundred thousand tons. Some of the dump runs as high as $6 to $8 per ton. Mr. Kilborn states that his company has made exhaustive tests of the ore and is satisfied they can handle it at a profit by the cyanide method. He expects to have the mill in operation by January 1907. He is shipping two cars of ore per day to the smelters.

Cripple Creek, June 14.

IDAHO.

IDAHO COUNTY.

Owing to the late heavy snows, all the mines of Buffalo Hump district have been closed. There will be abundance of water for placer mining operations throughout the summer season.—— James Surridge, general manager of the Newsome Legget Mining Co., says his company has expended over $30,000 developing its placer property and is opening up one of the largest gold bearing gravel deposits in Idaho. It has reached a depth of 140 ft. without finding bedrock. Fine gold is found from the grass roots down, and the property is now being worked at a profit. Two giants are operated day and night.

NEVADA.

CHURCHILL COUNTY.

At Fairview several properties are producing ore in quantities. The Nevada Hills is sacking $300 to $500 ore from four openings within a distance of 1,600 ft. along the vein. On this vein, a few hundred feet distant, are the properties of the Ida Mines Co., where systematic trenching is in progress to determine the course of the veins and position of the ore-shoots.

ELKO COUNTY.

An important strike is reported in the Protection mine at Mountain City, operated by Wm. Willis. In a 900-ft. adit, being run to open up the main vein, a large body of white quartz has been cut. Selected ore assays $800 gold and $3,500 silver. For two years Mr. Willis has been engaged in development work. He is preparing to put in a mill.

LINCOLN COUNTY.

(Special Correspondence.)—Progress in Searchlight district is now marked by visits from some well-known mining men. The San Francisco calamity has caused many to turn their attention to the Nevada mining camps with the hope of recouping their lost fortunes. W. H. Malone, of Denver, president of the Frier Hill mine, at Leadville, and A. A. McKnight, of Bullfrog, who are reported to represent Chas. M. Schwab, have left Searchlight, after having spent several days inspecting some of the most prominent mines here.——H. B. Adsit, of Denver, was also in Searchlight several days last week, when he acquired additional property and concluded arrangements to open headquarters here.——The final payment on the bond on the McGhan group has been made. This property consists of 20 claims situated at the northern end of the district and has been deeded to the Nevada Consolidated Mines (Ltd.). The company was organized by Geo. P. Spittall, of Philadelphia, last January to take over the McGhan group. At that time Mr. Spittall and associates took a year's working bond on the group, which, under the direction of F. O. Woods, has turned out so satisfactorily that the bond holders decided not to wait until the expiration of the stipulated time.——In El Dorado district, development is improving the Venus, and rich strikes are reported. Recent samples in the bottom of the shaft of the Venus averaged 20 oz. gold per ton. These samples were taken in sulphide ore, although there is some free gold in the rock. The management is sinking for the 200-ft. level and will continue cutting stations at each 100-ft. until the 500-ft. level is reached. Two shifts of three men each are employed in sinking the shaft.——Drilling machinery for the Black Hawk is on the way, and drilling for water for mill purposes will begin immediately on its arrival.——Preparations are being made to begin a 500-ft. shaft in the Mountain-El Dorado group. ——The Nevada-El Dorado at the 200-ft. level has uncovered ore which is reported to run $75 per ton. Drifting has begun. There is a large quantity of high-grade free-milling ore on the dump, which, as in many other cases in this section, is being held for shipment until the railroad, now under construction, reaches Searchlight.

Searchlight, June 14.

(Special Correspondence).—Among the new companies recently organized here, is the Searchlight-Bronco Mining Co., which owns seven claims eight miles southeast of Searchlight.—— The Nevada-Searchlight has begun sinking an additional 100 ft. from its present depth of 80 ft. In following the hanging wall, the streak of good ore found on the surface has widened. —— The Cyrus Noble Mining Co. has been having trouble with the new electric pump recently installed, but it has been put in working order, and is now doing good service. Concentrators have also been installed, and are expected to raise the percentage of extraction. Sinking an additional 100 ft. will be begun at once.—— The Quartette Mining Co. reports having struck water in the Drake shaft at a depth of 238 ft. As the present flow is slight, sinking will continue, the expectation being that it will tap the Quartette-Cyrus Noble vein within the next 50 ft., and that with greater depth the flow of water will increase to such a quantity as to give an ample supply for the additional 20 stamps now being put in.—— The Wyoming-Searchlight, having reached the 200-ft. level, has suspended operations pending the arrival and installation of a hoist, the whip being inadequate for further depth. As this property is situated on the flat, its development is watched with interest, for, if successful, it will enlarge the proved area of the district. The value of the ore obtained at the 200-ft. level more than doubles that from the 100 level.—— The Cyrus Noble Extension Mining Co. is proving up better as the shaft goes down. Recent samples taken from the bottom of the 60-ft. shaft gave satisfactory assays, and sinking will proceed. A whip will be put in on this mine in a few days.——The Searchlight Mining & Milling Co. reports that it intends to enlarge the mill on that property to 20 stamps. Rich ore is being taken out and one small lot, milled last week, ran $2,000 per ton; the average is about $25 per ton.

NEW MEXICO.

DONA ANA COUNTY.

E. A. Franke, general manager of the Modoc Mining Co., at Organs, reports that the wet process, lately installed at the mines, is proving a success and that the mill is running at a profit.—— Geo. P. Courtney, assistant manager, at Dona Dora mines near Kent, reports having run into a rich silver-gold vein in the Oriental adit.

OTERO COUNTY.

The vein on the 200-ft. level of the Lucky mine at Jarilla is 20 ft. wide, and a new raise has been started in this level north of the shaft. The north drift on the second level has penetrated the rich body of sulphide opened on the first level.

SOUTH DAKOTA.

CUSTER COUNTY.

It is reported that the Harney Peak Tin Mining Co. is to be reorganized and will soon resume operations on a larger scale. The English and American factions in the company, have at last compromised their differences and agreed upon a plan of action. The necessary capital has been secured for development and putting the mills in order. The Harney Peak Co. is one of the largest owners of property in the Black Hills, holding several thousand acres in Pennington and Custer counties, embracing mineral and timber lands, and placer claims. During the former period of the company's activity, a number of shafts were sunk, exposing large bodies of ore. Two mills were erected but were never operated on a commercial basis. One plant at Hill City, costing a quarter of a million dollars, never turned a wheel save in a trial of the machinery—not a test upon the value of the ore.

LAWRENCE COUNTY.

The New England Homestake Co., sinking a shaft two miles above Deadwood, has put in a new and larger compressor. The shaft is down 175 ft. in hard rock.

PENNINGTON COUNTY.

At the Gertie mine, one mile above Hill City, on Spring creek, an incline shaft 500 ft. in depth has been sunk on ore the entire distance. A year ago, after exploiting the mine, E. C. Johnson, the owner, erected a one-stamp mill, and put in a Wilfley concentrator. After a quantity of tin concentrate had accumulated, a reverberatory furnace was built in which the ore was smelted. Excepting mining, all other work at the Gertie has been experimental. The next step will be erection of a modern plant. Having proved the extent and value of the orebody and demonstrated the adaptability of the machinery and treatment, the Gertie mine will be the first Black Hills mine to produce metallic tin on a commercial scale.

WASHINGTON.

CHELAN COUNTY.

(Special Correspondence).—N. G. Blalock has filed a claim on Lake Chelan for a storage reservoir, and on 3,500 cu. ft. of the flow on the Chelan river. He has been interested in mines in the Chelan country for several years and is said to have recently associated Jay P. Graves, of Spokane, with him in the Holden mine. It is believed that Mr. Blalock and Mr. Graves contemplate building an electric railway from Lake Chelan to Spokane, the Chelan River falls to be used to generate electric power for it and the mines. Mr. Blalock is reported to have said that $3,500,000 will be expended on mine and power development.

Spokane, June 14.

FERRY COUNTY.

(Special Correspondence).—The Palmer Mountain Tunnel & Power Co. has placed the contract for a 300-ton stamp and cyaniding mill with the Denver Engineering Co. The Palmer Mountain tunnel has intersected 24 veins, the ore from which will be treated by the cyanide process. Electric drills are to be used, each drill to be run by a separate electrically driven compressor. Men have been started at work on the foundation for the mill. As soon as the first three drills are received, work will be resumed in the adit, and on some of the veins crossed by it. Power for both adit and mill will be supplied from the company's power-house on Toats Coule creek.—Work is going ahead in the lower adit of the Pinnacle group, on Palmer mountain, and the force is to be increased.—— The inclined shaft on the Copper World is down 50 ft. and has cut into a body of shipping ore. Native copper is reported in some of it.—— Some new equipment has been ordered, and when it arrives another drill will be started at the Copper World Extension mine. Good progress is being made in sinking the shaft on this property below the 200-ft. level.—— Capital subscribed at Spokane is to develop the Horn Silver mine, in which good ore was found some years ago.

Loomis, June 12.

(Special Correspondence.)—J. J. Browne, of Spokane, has returned from a trip into Okanogan county, and reports greater activity in that section than ever before in its history. He says, at Oroville they show fine specimens of molybdenite from a new discovery 12 miles above that place, in the direction of Conconnully, on Pine creek. They had been working on it 10 days. At first they had 10 in., but the vein has broadened to three or four feet and the miners have 100 sacks ready for shipment.—— John J. Cole, of Findlay, O., Mr. Barr of Boston, and other capitalists, have been in that country looking into the property of the Copper World Extension, planning to put money into its development.—— A body of high-grade ore has been encountered in the shaft of the Copper World at a depth of 50 ft.—— On the foot-wall is a sheet of native copper. The ore is mostly bornite. J. L. Drumheller, of Spokane, has a seven months' option on the Benvenue, three miles north of Myers Falls. It is a gold proposition.

Spokane, June 14.

STEVENS COUNTY.

(Special Correspondence).—A rich blind vein of silver-lead ore was recently found in the Metalline mine while driving an adit. Since the first vein in the tunnel was encountered, another four feet in width was crossed, the ore running 20% lead and also carrying silver. A steam-drill is in use and the adit is advancing three feet per day. Drifts are being cut on both veins. Over a carload of ore has been extracted in the course of development.—— The Silver-Lead Mining & Smelting Co., in Metalline district, has put up buildings for mess and bunkhouses and has started work in the mine; transportation up the Pend d'Oreille river has been made a possibility, and a boat is being built. Boats are now running from Newport to Box canyon, and the Government has lately completed a wagon road around the canyon, which follows the river and connects with private roads to the mines.

—— Nearly a month ago, a new vein was encountered in a cross-cut from the bottom of the shaft in the Lucky Bill mine, four miles northeast of Newport. This vein is four feet wide at the face. The ore averages $7 gold and $7 silver and copper. Three parallel veins, discovered at the surface, will be crossed by the adit.—— Some years ago work was done on the Bonanza mine at Bossburg, and the machinery was afterward removed to another property. Work was lately resumed at the Bonanza under Canadian management, and new machinery is being installed. The Bonanza ore is low grade, but it is thought the mine will yield 1,000 tons per month, which will pay a profit.

Republic, June 12.

CANADA.

ONTARIO.

Plans and estimates for converting the Temiskaming railway, from North Bay to Englehart, to an electric road, are being considered by the Ontario government. The distance is 137 miles, and the cost is placed at $1,000,000. This will cheapen transportation to and from the Cobalt mines.

BRITISH COLUMBIA.

The Tyee Copper Co. (Ltd.), at Duncans Station, Vancouver Island, reports smelter returns for May as follows: Smelter ran 13 days and treated 1,915 tons of Tyee ore, giving a return, after deduction of freight and refining charges, of $38,177.

The British Columbia Copper Co.'s smelter has been blown out for enlargement. The Granby smelter received nearly 3,000 tons more ore than during the previous week, making a total increase of that much over last week's Boundary ore shipments. The shipments for the week ending June 9 were: To Granby smelter from Granby mines, 18,339 tons; from Skylark, 25 tons. To British Columbia Copper Co.'s smelter from Brooklyn-Stemwinder, 2,145 tons; from Rawhide, 627 tons; from Sunset, 825 tons; from Mountain Rose, 33 tons. To Trail smelter from Providence, 40 tons. Total shipments for week, 24,339 tons; total for the year to date, 555,312 tons. Smelter treatment for the week was: Granby smelter, 17,225 tons; British Columbia Copper Co. smelter, 1,338 tons; Dominion Copper Co. smelter, 3,630 tons; total for week, 22,693 tons; total for year to date, 567,101 tons.

Following were the ore shipments from Boundary mines for the week ending June 16: Boundary mines, at Phoenix, 18,976; Brooklyn-Stemwinder of Dominion Copper Co., at Phoenix, 3,333; Rawhide, at Phoenix, 330; Sunset, at Deadwood, 990; Mountain Rose, 60; Emma, at Summit, 454; Providence, at Providence, 30; total, 24,173. Ore was treated at the smelters during the week as follows: Granby Co., 17,153; Dominion Copper Co., 4,683. Total, 21,836. Total for year, 588,937 tons.——J. J. Martin of Phoenix has bonded 700 acres of mineral and comprising more than 20 claims at Phoenix, to New York and Spokane people. Extensive prospecting and development are to be systematically carried on.

(Special Correspondence.)—The Maple Leaf group near Grand Forks has been bonded for $60,000.—— The Hall mines smelter at Nelson is finishing additions which will cost $75,000 and includes the adoption of the Huntington-Heberlein process and the erection of a complete mill.—— Boston capitalists have taken a bond for $100,000 on the Big Copper mine, near Phoenix, and will put a large force at work.

Phoenix, June 8.

MEXICO.

DURANGO.

(Special Correspondence).—The new 1,000-ton smelter of the Valardena Mining & Smelting Co. is rapidly nearing completion and the old mines are being put in condition to supply ore to this plant. The concentrator of 200-tons capacity is running.

Valardena, June 15.

JALISCO.

The National Metal Co., operating in the Etzatlan district, is said to have completed arrangements for the establishment of an ore-buying branch in Etzatlan and quarters have been secured not far from the Mexican Central station. The new branch will be in charge of Ernest Honigman, who has been connected with mining enterprises in Mexico for several years. E. S. Dewey, manager of the National Metal Co., at Guadalajara, is connected with the establishment of the new branch. The rapid development of the Etzatlan and Hostotipaquillo mining districts is responsible for this move on the part of the National Metal Company.

A company is being formed at Guadalajara to work the Virgin de Guadalupe placer in the Tapalpa district. It will be known as the Compania Minera Internacional. The Virgin de Guadalupe was sold last December by Alberto Palos, who denounced it, to Silviano Camberos and Jesus Martinez.

Books Reviewed.

Report on the Operation of the Coal Testing Plant of the United States Geological Survey at the Louisiana Purchase Exposition, St. Louis, Mo., 1904, Edward W. Parker, Joseph A. Holmes, Marius R. Campbell, Committee in Charge. Part I, Introduction, by Edward W. Parker; Field Work, Classification of Coals, by Marius R. Campbell; Work of the Chemical Laboratory, by N. W. Lord, pp. 300, map and ill. Part II, Boiler Tests, by L. P. Breckenridge, pp. 681, ill. Part III, Producer Gas Tests, by Robt. H. Fernald; Coking Tests, by Fred W. Stammler; Melting Tests with Cokes, by Dr. Richard Moldenke; Briquetting Tests, by Joseph Hyde Pratt; Washing Tests, by John D. Wick, pp. 493.

This bulky report gives in much detail an account of the equipment of the coal-testing plant at St. Louis, the methods employed and the precautions taken to ensure accuracy in the data obtained. A preliminary statement of the more striking features of the work was published by the Survey a year ago as Bulletin No. 261, but a careful perusal of these three volumes will well repay anyone who read that bulletin.

When, early in 1904, the plans of the projected coal-testing plant at the World's Fair were published and attention was called to what the plant could do for the American coal trade, the writer took occasion to point out elsewhere that the results obtained might have far less scientific and commercial value than the promoters of the proposed trials anticipated. He based his views on these facts: To be of any permanent scientific value, not only would the tests have to be conducted with greater thoroughness than seemed possible at a plant dependent for its equipment on the generosity of exhibitors at the Fair, but also the coals would have to represent the average output of the mines whence they came; unless there were checks by mine sampling and the inspection of coal at the tipple, some operators on the lookout for a little inexpensive advertising would ship coal to the testing plant that was a long way from being a sample of their regular output. And if the systematic sampling of a selected mine in every important coal-producing center were possible, the tonnage forwarded would be utterly beyond the capacity of the plant. Hence there was a danger that if the coals tested fairly represented the mines from which they came, the mines selected would not represent the important fields. Moreover, so far as foreign trade was concerned, the tests proposed would be of comparatively little importance since, valuable as analyses and proofs of efficiency might be for advertising purposes, other factors ruled the export trade, the chief of these being ocean freight rates and the condition and composition of the coal that the foreign consumer receives. Happily, as the event has proved, any doubts as to the permanent value of the work undertaken were not justified.

Messrs. Holmes, Parker, and Campbell, the committee in charge, found out long before the plant was completed that more coal would be offered for testing than could be handled. They also clearly perceived the importance of careful and frequent checks and the necessity of sampling the seam whence each coal was mined; and finally they recognized that the results would be of most value if attention was concentrated on the needs of the home consumer. As a result they did not attempt too much with the equipment provided, and let the export trade look out for itself. Their choice of mines was largely, no doubt, governed by the location of the plant. Hence small mines in States that rank low as producers received attention not given the great mines of Pennsylvania, Illinois, and Ohio, but four mines in these three States being sampled for the various tests and but six carload lots of coal being received from them, though the States rank first, second, and fourth as producers and their combined output in 1904 was 232,018,848 tons.

Whatever causes governed the selection of mines, the actual result has been most happy. For had the mines been chosen with regard to present size and value of output, three or four States would have monopolized the plant and the tests would have given results far less reliable and suggestive. In fact, it is not too much to say that as a result of the committee's care, forethought, and good judgment, their report is a unique addition to the literature of coal.

So far as the writer is aware, no nation has ever undertaken to analyze under standardized conditions and compare in so many ways such a variety of coals. The German Government has a testing laboratory just outside Berlin that covers a wide field of work, and the Belgian Government, at Framieres, has what is probably the finest coal-mining experiment station in the world,

but at neither of these places has any work been done that is in the same class with that done at the plant at St. Louis. As for Great Britain, until 1899 the leading coal-producing country of the world, practically all that has been undertaken there has been carried through by firms or by individuals with the exception of occasional steaming tests under the supervision of the Admiralty. One can find in the voluminous report of the Royal Commission information on every phase of the occurrence, mining, transportation, and use of coal, and that report, the final volume of which is yet to appear, will always be a storehouse of information to anyone interested in the coal industry of the United Kingdom and of the world. Yet valuable as is that work, it is doubtful if any such compilation of miscellaneous evidence can give the direct benefits of an investigation of narrower scope, undertaken on a scientific basis, which shows by direct comparison under standardized conditions the relative values of different coals and emphasizes the importance of new developments in the utilization of their energy.

One fact that will gain for the work at St. Louis favorable recognition is the timeliness of the undertaking. Had the Government carried through a much more comprehensive series of tests twenty years ago, when the word inexhaustible was freely applied to all fuel supplies, and when coal was generally sold on the strength of trade names, the results would have been of less immediate utility because consumers would not have been prepared to follow out suggestions looking to the conservation of our fuel resources. As an instance of the change in public opinion may be cited the utter indifference of State legislatures to the ruthless waste of natural gas in Ohio, Indiana, and Pennsylvania during the late '80s, when millions upon millions of cubic feet were allowed to burn in huge flambeaux for no better purpose than to promote the sale of house lots in boom towns. The geologist who foresaw and foretold the inevitable exhaustion of the underground reservoirs found his warnings fell on deaf ears. Today in most States producing natural gas, there are adequate laws for preventing waste, and the enforcement of these laws meets public approval. If a great gasser in Indian Territory roars away beyond control for a week or two, the energy wasted is commented on by the press.

As another instance of the present attitude toward fuel losses may be cited the central power stations being erected in the Pennsylvania anthracite districts, and in the bituminous fields of that State and of West Virginia. Water-tube boilers, grates for burning small coal, fuel economizers, careful insulation of steam mains all show that even at the mines coal is not to be wasted. In fact, practically all the trusts that figure so largely in the current discussion of tendencies in production and distribution are setting an example in small economies, the conservation of what has been thrown away, that lesser corporations must follow. Hence it is absolutely certain that the endeavor to utilize to the utmost sources of energy and raw materials will be a more and more prominent factor in the industrial life of this nation. Therefore such work as that conducted under the supervision of Messrs. Parker, Holmes, and Campbell, calling attention to the immense gains possible in the utilization of the stored energy of our coal fields has a peculiar worth not only in the actual possibilities shown, but in indicating to a public ready to make the most of these possibilities the importance of further work along the same lines and the high value of similar research in other branches of production.

SAMUEL SANFORD.

Washington, May 1906.

The ore movement at Duluth, Minn., this year is tremendous and gaining in volume and speed weekly. It has always been the fear that the two Minnesota roads owned by the United States Steel Corporation would operate to the advantage of that company and sidetrack or delay, when convenient, outside and independent shippers. That this is not the case is a matter that is now causing much favorable comment. In the case of the Duluth, Missabe & Northern there might be more excuse for such action than with others, so enormous is the tonnage it is handling for its owner in the short season—10,000,000 tons—and so vast is its expectation of total business. Eleven million tons of ore moved in a single season by one road is a total large enough to stagger the imagination.—From 'Iron Age.'

Additional Mining Summary.

NEVADA.

LINCOLN COUNTY.

Affairs at the mines of the Bamberger-De Lamar Co., at De Lamar, are gradually assuming their former condition. Connection with the vein, opened some time ago on No. 6 level, has been since made with it at the three, five and seven. A cross-cut on the former shows 40 ft. of ore, the average value of which is better than any that has been milled under the present administration.——The lease on the Magnolia group operated by Harry Lowry, is proving satisfactory, and while the tonnage of ore sent to the Salt Lake furnaces is not large, it is affording an average of nearly $200 per ton gold and silver. Meanwhile, the lessee is opening up a considerable tonnage of ore that will be reduced at the mill by the company, the lessee being permitted to appropriate the shipping ore only under the terms of his franchise.

NYE COUNTY.

A copper find has been made in Jackson Mountain district by N. B. Robinson who, aided by Goldfield people, will open up the vein which is 75 ft. across. The property was located a year ago by Robinson, but the copper discovery was only made a few days since.

(Special Correspondence).—Times in this camp are improving rapidly. Since the Las Vegas & Tonopah railroad has advanced its office to Johnnie siding, Indian Springs is a thing of the past. At the new station teams are on all sides clamoring for room to load freight for Bullfrog, Johnnie and other points. The newsboy, on the arrival of trains, is the latest feature. Stage fare to Beatty is $14, distance 45 miles up the Armagosa desert. The track-laying outfit is 15 miles out, laying steel at the rate of two miles daily. Mines and prospects are being transferred, some for cash, others on option. Fred Boller, a lessee, who made a strike on one of the claims of the Johnnie Consolidated group, four weeks ago, yesterday opened up another vein 30 in. wide and parallel to his first find and 30 ft. to the east. He is taking out ore showing much coarse gold. It creates no excitement. These 'Chuckawallas' simply look wise and say, "I told you so."——McClanahan, Moser & Smith have bonded to Mr. Filsley, for 45 days, two prospects for $3,000. Assays run from $18 to $114 per ton, with a 5 to 18-ft. vein. Since the automobile and daily stage-line commenced running between here and Johnnie siding, strangers are coming in from all directions. It is reported that a 40-stamp mill is coming from the east (Denver, I think), and a cyanide plant is part of the outfit. The Thomas Co. is arranging to put a mill on its property. As many as 30 mines and prospects have changed hands here inside the past 60 days, and all at good figures. I have just heard of a contract being signed for building a two-story hotel and four concrete private dwellings.——Fred Boller and Wm. Waters are just in from the new strike on the Johnnie Consolidated. They bring samples of 31 sacks of ore which they believe to be worth $20,000 per ton. They broke into this streak after six o'clock last night and worked all night sacking the ton and a half. They have 12 in. of this ore on the foot-wall and 18 in. of $1,000 ore, which they followed down from the surface.

Johnnie, June 18.

WASHOE COUNTY.

C. L. Dignowity is reported to have bought the Reno-Mizpah mines in Peavine district, northwest of Reno. These mines are in active operation.

WHITE PINE COUNTY.

Samuel Newhouse is reported to have offered $50,000 for a mining claim at Cherry creek. It is owned by Blain Grey and family and has been held by the Greys for 40 years.

The New Zealand government is asking for bids for piercing a tunnel over five and one-quarter miles long, much longer than any railroad tunnel in the Southern hemisphere. The tunnel is to be bored through the main central range of mountains of the Middle island at Arthur's pass. It will pass under the coach road through Otiria gorge, a well known scenic gorge. The tunnel will form part of a railroad now under construction connecting the east and west coast districts of the Middle island. The lowest passes in the dividing range are 3,000 ft. high. The ascent from the western side is steep, through a difficult country for railroad building. The road has been completed and opened for traffic to a point about two miles from the western end of the tunnel. It is proposed to operate the tunnel section of the road, when completed, by electricity generated by power obtained from the Otira river.—From 'The American Manufacturer.'

Personals.

Percy L. Fearn is at Butte.

J. H. Curle writes from Seoul, Korea.

B. B. Thayer has returned from Butte to New York.

Chester F. Lee, of Seattle, visited San Francisco this week.

Frank McLaughlin of Santa Cruz, is visiting San Francisco.

Eugene Braden has gone on a short visit to Helena, Montana.

E. C. Musgrave is now living at Victoria, British Columbia.

Frederic J. Siebert starts this week for Glasgow, Scotland.

H. L. Slosson, of San Francisco, has gone to Virginia City, Nevada.

Olof Wenstrom has returned to Boston, after a lengthy stay in Mexico.

John Dern is president of the newly organized Bingham Mines Co., at Bingham.

R. M. Atwood, of Helena, is general manager of the new Cliff Mining Co., at Ophir, Utah.

Ernest H. Simonds has returned to Berkeley from an examination near Austin, Nevada.

H. M. Sweet, secretary of the Bingham Consolidated mines, has been on a visit to Salt Lake City.

Everard Arnold, on his return from sampling a Fresno copper mine, has gone to Grass Valley.

M. A. Daugherty, of Salt Lake City, is manager of the Carbonate Hill Mining Co., in Morgan county, Utah.

Walter Van Matre is superintendent of the Washington mine at French Gulch, Shasta county, California.

James Douglas delivered an address before the science members of the graduating class of Columbia University.

S. Herbert Williams, of Boston, consulting engineer to the Shawmut Mining Co. at Bingham, has been in Utah on an inspection trip.

Frank Brown, of Lewiston, Idaho, formerly manager of the Jumbo mine at Buffalo Hump, leaves for Nome, Alaska, to develop a bismuth vein.

Charles F. Porter, of Salt Lake City, has been made a director and purchasing agent for the Nevada Gold Mines Co., operating in Lincoln county, Nevada.

Arthur W. Stevens, of Chicago, has just returned from making extensive examinations of properties in Wisconsin, and leaves at once for Idaho to examine several large placer properties for Chicago capitalists.

J. B. Higgins, senior mine captain of the Simmer & Jack mine, at Johannesburg, is visiting New York. He is on his way to his former home at Reno, Nevada, and returns to his duties within six months, traveling through Japan and India.

J. V. N. Dorr, manager of the cyanide mill, of Lundberg, Dorr & Wilson, Terry, S. D., was in Denver last week in the interests of the Horseshoe Mining Co., for which company he is consulting engineer in the reconstruction of their cyanide mill at Pluma, South Dakota.

H. Kenyon Burch, who has been with the Detroit Copper Mining Co., of Arizona, for the past three years, and recently constructed the new 1,200-ton concentrator for the above company at Morenci, Ariz., has resigned his position and will leave in a few days for an extended trip north and west, to inspect the different concentrators and power-plants. Then he will go with the Montezuma Copper Co., of Nacozari, Mexico, as chief engineer in charge of construction and will build a new mill for this company of about the same capacity, and on the same lines as the mill at Morenci.

Obituary.

William A. Akers died at Los Angeles on June 17 by reason of injuries received in an automobile accident the night previous. He was a mining engineer of established reputation, having filled many important positions. At one time he was manager of the Combination Mining & Milling Company, at Hope, Montana, and afterward he was with the Colorado Mining & Smelting Company at Butte. Then he became manager of the Sheridan-Mendota mines at Telluride and in 1895 he had charge of the Golden Fleece mine, when it was in bonanza. Later he opened an office as consulting engineer at Salt Lake City. Recently he was under retainer from the Amalgamated Copper Company, having an office first at Hermosillo, in Mexico, and then El Paso,

Texas. He moved to Los Angeles in January of the current year. In March he visited San Francisco. Akers was regarded as an especially well-informed engineer; he was an expert witness in many important mining cases, such as the Bell-Speculator, the Mammoth-Grand Central, and the Heinze-Amalgamated litigation. He was a man of particular courtesy of manner, which, with other sterling qualities, made him many friends. His sudden death will bring a cloud to many of those that go down in mines. It remains but to add that he was about 46 years of age and leaves a wife, formerly Miss Stanley of Butte.

Trade Treatises.

The Ingersoll-Rand Co. have issued Bulletin No. 2,007, on their Imperial piston-drill, an indispensable tool in the machine shop and mill. These machines and all their working parts are fully described and illustrated. Their catalogue, D 43, is a handsomely illustrated treatise on machine rock-drills, showing their varied application under many conditions. Catalogue X 136 describes and illustrates the Imperial, Type 11, air-compressors made by the Ingersoll-Rand Co., of 11 Broadway, New York.

Commercial Paragraphs.

One of the largest establishments for the reduction and sampling of ore in Nevada is now nearing completion at Tonopah, for the Tonopah Sampling & Ore Purchasing Co. The methods employed for handling large quantities of ore utilize the most approved modern appliances. The main building is provided with eight storage and two receiving bins, each with a capacity of 100 tons. These are connected with three bucket-elevators used in conveying ore to the top story, whence it descends by gravity through the various chambers and grinders and is distributed finally through chutes to proper receptacles, ready for the assayer. Every operation is performed automatically. The plant will be electrically operated. A transformer house has been erected adjacent to the main building in which three transformers are installed. Eighty-five tons of ore will be treated daily when the plant is in regular operation This output can be readily increased by the addition of equipment. The entire plant is being furnished by the Allis-Chalmers Co. of Milwaukee.

The Colorado Iron Works Co., of Denver, reports constant shipments of ore received to be treated at its testing plant. These shipments vary from 25 lb. to one or more carloads. A recent 500-lb. shipment came from Japan; others have come from Mexico, the Philippines, Australia, and South America, as well as from points all over the western half of North America. The company's testing facilities include stamp-milling, amalgamation, concentration, cyanidation, with all the modern accessories for each process.

Crocker-Wheeler Co., of Ampere, N. J., has received an order from Columbia University, New York, for one 450-kw. 250-volt direct-current generator for lighting and power for the University.

Tourmaline and Topaz in California.—The southern counties of California bid fair to rival the Ural mountains in the production of tourmaline, beryl, topaz, and the other precious stones which have been the pride of that region for the last half century. The Pala region in San Diego county has become especially noted in gem production, and George F. Kunz of the United States Geological Survey, calls attention in his forthcoming report on the production of precious stones in 1905 to the fact that a number of adjacent localities give indication of yielding the same minerals.

The authorities of Birmingham university have recently opened on the university grounds an experimental coal mine, occupying nearly an acre of ground. The purpose is to give practical instruction to students in all the problems and operations of coal mining. They are exercised in underground surveying, the connection of surface with underground surveys, the testing of ventilation, the measurement of air volumes and velocities, the friction of air currents, the various methods of breaking coal, and the management of different kinds of drills and cutting machines. The completion of this artificial mine has been awaited with interest, and it is expected to prove very valuable in teaching the science of mining.—From 'The American Manufacturer.'

Natural Soda in Mexico.—Under the blazing sun of the desert, surrounded by barren and bleak sand dunes, lie lakes of crystals of carbonate of soda, to all appearances great masses of snow and ice, but in reality a substance from which can be made both soap and glass. At only one other place in the world is natural soda found under conditions which admit of industrial development, and at that place it must be shipped several hundred miles by rail, and many tons of water must be evaporated by coal to obtain a ton of the product. The Mexican lakes are within 3,000 yd. of the sea and the fierce sun and heat of the desert attend to the evaporation. The world's consumption is very large, and at present nearly all of it is manufactured from common salt with the use of expensive machinery. At Adair bay, when the temperature is right, the water of the lake crystallizes into pure carbonate of soda, nature doing what man requires machinery and coal to do. The Mexican Government declines to dispose of these lakes to anyone, President Diaz believing that they may become sources of income to the country, just as the nitrate of soda beds are to Chile. What it may mean to the soap and glass industry of Mexico may be judged when it is stated that at present manufactured soda, one of the principal items of cost, sells for $75 per ton in port, while the same article from Adair bay may be delivered for less than one-third of that price.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 10 Bacon Block, Oakland, has official reports of the following United States patents issued to Pacific Coast inventors:

Patents Issued June 12, 1906

823,458.—**Fountain Paint-Brush.**—C. H. Abbott, Whittier, Cal.

822,912.—**Concentrator.**—M. P. Boss, San Francisco, Cal.

822,913.—**Crushing Mill.**—M. P. Boss, San Francisco, Cal.

822,914.—**Motor for Stamp-Mills.**—M. P. Boss, San Francisco, Cal.

823,391.—**Apparatus for Applying Liquids to Covers of Receptacles.**—W. C. Buhles, San Francisco, Cal.

823,204.—**Glove.**—R. N. Carson, San Francisco, Cal.

823,263.—**Briquet Press.**—J. J. Crawford, Oakland, Cal.

823,040.—**Automatic Safety Trolley-Pole.**—J. R. French, Los Angeles, Cal.

822,940.—**Apparatus for Recovering Precious Metals.**—E. J. Garvin, Portland, Ore.

823,406.—**Rule Marker.**—J. L. Gastineau, Alhambra, Cal.

823,213.—**Combined Hook and Box.**—E. E. Gibson, San Francisco, Cal.

823,167.—**Dental Disk Shield.**—W. F. Green, Modesto, Cal.

822,950.—**Water Service.**—W. C. James, Los Angeles, Cal.

823,045.—**Folding Bed.**—W. C. James, Los Angeles, Cal.

823,174.—**Lock.**—J. Jorgenson, San Francisco, Cal.

823,221.—**Lock.**—J. Jorgenson, San Francisco, Cal.

823,222.—**Lock.**—J. Jorgenson, San Francisco, Cal.

823,337.—**Weeder.**—J. H. Lamdry, Moro, Ore.

823,282.—**Head and Filler for Liquid Receptacles.**—D. Landau, San Francisco, Cal.

823,059.—**Rock Drill.**—E. Leichter, Nevada City, Cal.

823,341.—**Mechanical Movement.**—F. N. Livingston, Ballard, Wash.

823,182.—**Incubator.**—O. W. Lutz, Petaluma, Cal.

822,967.—**Gripper for Printing Presses.**—F. I. Macauley, Alameda, Cal.

823,060.—**Fluid-Pressure Motor.**—Magney & Masterman, Los Angeles, Cal.

822,969.—**Badge and Watch Guard.**—Martin & Stockton, Snohomish, Wash.

823,138.—**Cheese Cutter.**—A. B. Roach, Los Angeles, Cal.

823,443.—**Hinge.**—F. Sandham, Los Angeles, Cal.

823,296.—**Detachable Calk Horseshoe.**—W. E. Shaw, San Francisco, Cal.

823,451.—**Joint.**—Sweeny & Sylva.—Los Angeles, Cal.

823,007.—**Hop-scoop.**—Charles True, Sherwood, Ore.

823,090.—**Phone Transmitter Attachment.**—R. A. Walton, Los Angeles, Cal.

823,091.—**Phone Switching Apparatus.**—R. A. Walton, Los Angeles, Cal.

823,092.—**Phone Transmitter Attachment.**—R. A. Walton, Los Angeles, Cal.

823,147.—**Railway Switch.**—E. Wartman, South Bend, Wash.

823,014.—**Cigar Protector.**—F. H. Whomes, Los Angeles, Cal.

38,077.—**(Design) Wall Pocket.**—C. A. Flanagan, Union, Ore.

822,403.—**Bicycle Seat Spring.**—Sweeney & Mayes, Orosi, Cal.

822,788.—**Protector for Horses' Tails.**—Tuthill & Boyd, Portland, Ore.

822,707.—**Automatic Dancing Figure.**—H. Wolke, San Francisco, Cal.

822,783.—**Course Finder.**—J. F. Smith, Everett, Wash.

The Difference between "Eureka" and The Other

is that one is "EUREKA" and the other isn't. The one "makes good" and the other doesn't. An engine or pump packed with "EUREKA" will give more service at one-half the cost of any other.

MAKE SURE TO GET GENUINE "EUREKA"

The Difference Between

THE ROBERTSON THOMPSON INDICATOR and some others is, it is not only handsome in appearance, but the working parts and springs are made to conform to U. S. Navy specifications and test. The other fellow don't do so. Special low prices and easy terms if you say so.

REDUCING WHEELS, PLANIMETERS, ETC.

JAS. L. ROBERTSON & SONS, Inc., - - - 195 Fulton Street, N. Y.

DIVIDEND NOTICE.

CALIFORNIA SAFE DEPOSIT AND TRUST CO., Cor. California and Montgomery Sts., San Francisco. For the six months ending June 30, 1906, dividends have been declared on the deposits in the savings department of this company as follows: On term deposits at the rate of 3 6-10 per cent per annum and on ordinary deposits at the rate of 3½ per cent per annum, free of taxes, and payable on and after Monday, July 2, 1906.

J. DALZELL BROWN, Manager.

DIVIDEND NOTICE.

SAN FRANCISCO SAVINGS UNION, NW. Cor. California and Montgomery Sts., San Francisco. For the half year ending 30th June, 1906, a dividend has been declared at the rates per annum of three and two-thirds (3 2-3) per cent on term deposits, and three and one-third (3 1-3) per cent on ordinary deposits, free of taxes, payable on and after Monday, July 2nd, 1906. Depositors are entitled to draw their dividends at any time during the succeeding half year. Dividend not drawn will be added to the deposit account, become a part thereof and earn dividend from July 1st.

LOVELL WHITE, Cashier.

DIVIDEND NOTICE.

GERMAN SAVINGS AND LOAN SOCIETY, 526 California St., San Francisco. For the half year ending June 30, 1906, a dividend has been declared at the rate of three and six-tenths (3 6-10) per cent per annum on all deposits, free of taxes, payable on and after Monday, July 2, 1906. Dividends not called for are added to and bear the same rate of interest as the principal from July 1, 1906.

EDITORIAL.

THE OUTPUT OF GOLD from the Rand during the month of May was 461,202 fine ounces, equivalent to $9,500,000. This is the highest production on record, being 20,000 ounces ahead of March, the previous maximum.

A CONTEMPORARY, waxing enthusiastic over the dredging operations in its vicinity, says that "the dredger in Yreka creek, at night, with its bright electric lights burning, and the clashing of its machinery, seems like a Mississippi river steamer, plowing along in the water, although remaining stationary." It must be "the ship" the hopeful ever expect, but that so rarely "comes in," even to those who invest in a form of enterprise as substantial as dredging.

COMPLAINTS come from the smaller mining camps of British Columbia that there is a shortage of labor. This is due in part to the requirements of the bigger mining centres, such as the Boundary district and Rossland, but the scarcity of miners is also attributable to the large number of men who are engaged in prospecting throughout British Columbia; which promises well for the future of the region. It is to be hoped that the active explorations now going on will prove rich in mineral discoveries.

CANDLESTICKS of the old-fashioned kind, made of solid silver, such as one finds in the old churches of Mexico, have doubtless been used on occasion as weapons of offense during revolutionary times; on the other hand, the miner's candlestick, made usually by a blacksmith proud of his skill, has been regarded as a convenience not only for holding the feeble dip that illuminates the miner's travels underground, but as a serviceable tool for prying out bits of vein-rock. The spear-like point intended to be stuck into the timber, to hold the light while the owner is taking notes or handling ore, has been made longer so as to permit of use as a small pick, in breaking a hand sample. But even a tool designed for good service can be perverted to base uses, and we learn that, at Bingham, Utah, a miner stabbed his shiftboss with his candlestick, inflicting what may prove a mortal wound. Thus does the candlestick become a stiletto.

IT APPEARS that the Arbitration Court established in Western Australia for the purpose of industrial conciliation has failed. At the annual meeting of the Chamber of Mines, Mr. Richard Hamilton, the president, said that "the application of the principle of compulsory arbitration to the settlement of industrial disputes has to be pronounced a failure, and the Act is in great danger of becoming a dead letter. Neither side has any faith in the Arbitration Court and both sides evince a desire to shun it as far as possible." Although the awards of the Court in important cases have been generally favorable to the employers, this has not helped them, for when they attempted to put the terms into effect, the laborers have simply refused to work under the conditions laid down and defied the decision of the Court. Even when the employers have declined to take full advantage of a favorable award—a sure sign of weakness somewhere—they have been unable to prevent a strike and subsequent embarrassment. Thus this method of avoiding labor troubles is a fiasco. It was the expression of class legislation, having been brought forward by the Labor party, the followers of which, evidently, broke faith, in refusing to accept the Court's decisions as soon as they found them to be adverse. It is a pity; for the method seemed, on the face of it, a good one. The result proves once more that no legislation can make men honorable and that the best preventative of trouble between employer and employee is fair dealing.

IT IS REPORTED from southern California that Mexican laborers engaged in laying track have refused to work, because of the intense heat, the steel rails actually blistering their calloused hands. No complaint was made as to wages, but the men declared they would not continue work during the heated term, at any price. During construction of the Southern Pacific Railroad in the vicinity of Yuma, in the early '80s, most of the rails were laid at night, when the temperature was a few degrees cooler than during the day. In summer in some portions of the desert region, the rocks became too hot to touch or to walk upon, and it is not uncommon for them to retain this high temperature, from 110° to 130°, throughout the night.

VALUES is a term in constant use, as a substitute for the metals. People extract 'values' out of an ore, they precipitate the 'values' in the zinc-box and they collect the 'values' by concentration. It is a bad usage and is indicative of slovenly writing. One does not precipitate or extract or collect the values any more than does these things to an arithmetic mean or a geometric ratio. The *value* of an ore signifies the amount of money represented by the metals contained in it as determined by assay; for assay-value is usually understood, any other value being too variable to signify anything intelligible. Why not say the *metals* when you mean metals? Of course the term to which we are making objection means the valuable metal or metals in an ore; well then, why not precipitate or extract or collect the gold, or the silver, or both precious metals, or the lead and copper? Why use these hazy terms and deal in such generalities when there is no need for it, save the tyranny of a bad custom? It may seem a small matter, but careful writing tends to clear thinking.

THE GEOLOGICAL SURVEY has encountered difficulties in obtaining the usual appropriation from Congress, the voting for that purpose having been preceded by some vigorous criticism. We are glad to note that no attempt was made to cut down the appropriation for geology, but the wood, water and arithmetic divisions received severe treatment, the result being that the money for hydrography was cut in two. It is pleasing to note that the members of Congress show little disposition to criticize the geological work of the Survey, although there is decided questioning as to the advisability of attempting so much work only thinly connected with geology. There is a probability that the reclamation service will be detached from the Survey permanently and if the hydrographic department is kept under restraint, we shall get back to conditions more favorable to the mining industry, that is, the real geological work will regain its proper relative importance.

THE PROBLEM of handling the vast tonnage of tailing discharged from the copper mills of Lake Superior has assumed such proportions in recent years that much ingenuity has been required in devising methods for disposing of this waste material. The largest mill crushes 8,000 tons of ore daily, and when it is understood that each ton of sand is accompanied by about 30 times its weight of water, the volume and weight of tailing to be considered, will be appreciated. Tailing-wheels to elevate the sand have been built and operated at great expense; the material is taken from the lowest floor of the mill and elevated 40 to 60 feet and in this manner enough fall

is gained to allow the sand to be carried away in long launders by the current of water and discharged into the nearest available dump, either one of the small lakes in the vicinity, or Lake Superior itself. Recently a novel device has been proposed; it is to dewater the tailing by means of classifiers, the water flowing in a sluice to the lake, the sand being conveyed by endless belts the desired distance, the conveyor running on idlers on top of the flume. The sand is to be discharged into the water just at the end of the flume, so that it may be distributed into deep water, as at present. This idea, it is thought, will make it possible to dispose of the mill-waste on a much lower gradient than by methods heretofore employed, and at a less ultimate expense.

Preventable Frauds.

During the past week two American adventurers, posing as promoters, were convicted in London of criminal practices in connection with the sale of shares in the American Mining, Milling, Smelting and so forth Company. It appears that they sold stock at big prices and on statements that were never verified. We have seen some of the circulars they sent out and it seems to us that people who are misled by such stuff deserve to lose their money. We look at it in this way: If intelligent people—for the unintelligent there is no basis of argument—put money in mining ventures without any knowledge as to the promoters or of the mine being promoted, and if they take no steps to secure advice, then they are flouting the profession which exists to give such advice. Anybody in London, Paris or Timbuctoo can secure a copy of some respectable mining paper and from it they can get the name of a mining engineer living near the scene of operations; if then they will write to him, not failing to enclose such a small fee as they would pay a lawyer or a doctor, it is likely that they will get sufficient advice to save them from a blunder. It is not necessary to see a mine to detect an imposture based upon it. Furthermore, the majority of people who are deluded by such adventurers are within easy reach of professional men and it is easy to go to one of them, show him the prospectus and ask him if it has the ear-marks of sound business. A mere glance is often enough to detect a fraud, for those that concoct such schemes do not expect them to pass the criticism of experienced mining men; on the contrary they prepare them as lures for the unwary, the simple, and the greedy among policemen, housemaids, clerks, retired military and naval people, and penurious clergymen. Old England and New England both contribute annually a large sum of money in this way, not to the mining industry, but to the *chevaliers d'industrie*—the knights of the financial highway.

Too many people are deterred from seeking professional advice because they know of no middle course between engaging an engineer at a big fee and going it alone without any sort of advice; and this is so because it does not occur to them to treat a mining engineer as they would a doctor or a lawyer, going to him for a consultation that need occupy only a few minutes and that should entail only a small fee. We have reason to believe that many experienced men who do not care to go to the ends of the earth except for an adequate honorarium will tender office advice to those who approach them in a proper way. It is time mining were treated as something better than gambling and mining engineers as something more businesslike than a hybrid between a professor and a promoter.

On the Rand.

Conditions in South Africa continue to be such that it may be said that they must become worse before they can be better. The crisis is likely to come next year when the Transvaal obtains self-government and the people then in control decide whether to retain the Chinese in the country or to return them whence they came. Recently the British Government issued a proclamation giving the Chinese a chance to go home and offering them assistance in the expense of repatriation. However, we learn from our correspondent at Johannesburg that after the proclamation had been posted two weeks, it became evident that they had no desire to leave; so that only a few of the coolies are likely to be lost to the mines. The nature of the position on the Rand can be inferred from the fact that the mining companies, by means of a test case, appealed to the Supreme Court of the Transvaal to prevent the posting of the repatriation notices in the Chinese compounds, but failed to stop it.

The fortunes of the white population of Johannesburg being identified for the most part with the success of the mines, the feeling is naturally one of irritation against the Home Government. They think that the officials in London interfere too much in South African affairs and that the mining community is the victim of a misguided paternalism. They pray to be delivered from the curse of politics. They would like to be let alone, to indenture Chinamen, control the Kaffirs, or do anything else essential to the needs of the business of gold mining. The future of South Africa is no particular affair of theirs, as compared to the immediate prosperity of the Rand. Most of them expect to return to their own country—Germany, England, or America, as the case may be—and all they ask is the chance to make money enough during the years of exile in the Transvaal. To such men the far-reaching effect of a statesman's policy is a secondary affair, compared to any hindrance to the uninterrupted extraction of gold from the 'banket.' They do not care for Chinamen or for Kaffirs and would be willing to let them go, provided other sources of labor supply could be discovered, but no other being forthcoming they think it sloppy sentiment to talk of 'slavery' and misguided charity to take too great an interest in the happiness either of the Mongolian or of the African native. To them he is a pawn in the game, in which pawns are sacrificed to the larger pieces on the board.

Meanwhile, the gold production increases; it is now 9½ million dollars per month. Yet the share market is lifeless and quotations recede steadily, with an acute uneasiness due to expectation of a crash at any moment, when forced liquidation may prove too much for the big houses. The decision of the Liberal cabinet at London to prohibit further importation of the Chinese until the Transvaal gets responsible government, next March, will cause the Chinese employed at the mines to dwindle in number, by sickness, accident and repatriation. What will happen next March no one can foretell, for it is not known what attitude the Boers will assume. They are opposed to the mining industry, which was the immediate cause of Kruger's corrupt politics and of his eventual downfall. The mining magnates, whom they tried to hector, and the mining men, over whom they tyrannized, got their revenge when the war swept the whole Boer regime into the Indian Ocean. No wonder the Boers do not like the gold miners; but they are shrewd and know their own interest, so that it is unlikely they will paralyze the industry which alone can keep the country from insolvency.

By the Way.

The London 'Times,' referring recently to the oldest of scientific institutes, the Royal Society, said:

The Royal Society, like every other association of human beings, has from time to time to provide itself with a new chief magistrate. More fortunate than the larger society of which we are all members it does this at fixed periods and with dispassionate gravity and decorum. Yesterday witnessed one of these recurrent changes, when, at the anniversary meeting, Sir William Huggins surrendered the presidency of the society into the capable hands of Lord Rayleigh. The astronomer, whose labors have done so much to give English astronomical science the distinguished place it occupies in the astronomical opinion of the world, is succeeded by a physicist who, by the breadth and variety of his research, the profundity of his knowledge, and the skill with which he has carried on the interrogation of nature, will rank among the greatest of those who have promoted that increase of natural knowledge which is the fundamental object of the Royal Society. It is worth noting that both men belong to a class of scientific investigators which, if not an exclusively English product, has certainly found more numerous representatives in this country than in any other. That is the class of men who live for science, not by science—men whose means render them independent of exertion, whose position offers many temptations to inaction, and whose abilities, if turned to remunerative pursuits, would ensure rich rewards of the kind that satisfies vulgar ambition. To men of this class—men who, according to one definition of amateurs, would have to be called amateurs, but who lift the word high above all vulgar connotation and restore its etymological significance—English science owes a debt that is simply incalculable. In that class, already sufficiently illustrious, we must include men like Michael Faraday, denied by fortune the power to give of their wealth to the cause of science, but nobly content to live in the utmost simplicity upon a pittance less than the wages of a skilled artisan, while working out discoveries that have changed the face of the world. It would be an evil day for England were the succession of gifted enthusiasts to come to an end, not only because their work is of a higher and more vivifying kind than that of ordinary men, but also because we are, and apparently are likely for some time to remain, very far behind in the organization of professional science. We are also far behind in the general diffusion of elementary scientific ideas.

The catholicity of the Royal Society is displayed by the fact mentioned by Lord Rayleigh, that all the medals which can be given to foreigners have this year been awarded to men of science in other countries. Assuming, as we must, that this has not happened through any desire to favor foreigners unduly, the pleasure derived from contemplating the impartiality of the Royal Society must be tempered by the inevitable reflection that we can hardly be keeping pace at home with what is done abroad. Peculiar interest attaches in the circumstances of the moment to the presence among us of Professor Mendeleeff, whose brief leave of absence from official duties covers, we believe, no more than the time required to receive in person the Copley medal awarded to him by the Royal Society. Though his own distinction as a chemist and as a man besides of wide and varied practical ability is a sufficient reason for the award, he modestly and rightly treated it as being also a testimony of sympathy with his country in her present trials. Official good-will is properly expressed through the Russian ambassador, who sat at the side of the president, but the sympathy of intellectual England with intellectual Russia finds welcome expression in the honor decreed to Professor Mendeleeff.

Under conditions where a weir could not be built, a novel way of measuring the flow of an artesian well was devised. Forty feet of 10-inch pipe was screwed into a 90° elbow on the pipe where it came out of the ground, and a hand force-pump attached to a small hole tapped into this pipe. The force-pump drew a red aniline liquid from a pail and injected it into the stream, where it was carried along with the water and at the same rate. By means of a stop-watch and the known carrying capacity of the pipe the flow of the well was easily determined.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

The best grades of zinc ore mined in the Joplin, Missouri, and adjacent fields, contain 55 to 60% zinc.

Tern plates are the so-called tin plates, made by dipping thin sheet iron into a bath of molten tin.

In Nevada the state law has fixed $4 as the value of a day's work performed on unpatented mining claims.

It is an easy matter to feed too much coke to a blast-furnace. The almost inevitable result will be to cause the fire to run upward and chill the tuyere zone.

Since the advent of the electro-magnetic separator into metallurgy, many old waste dumps containing low-grade or mixed sulphide ore, have been profitably worked.

Heap-roasting of sulphide ore is less expensive than roasting in stalls or in furnaces, but the practice of heap-roasting is more destructive of vegetation than either of the latter.

The fact that an ore deposit is superficial—does not go down—is no indication of its poverty. Some shallow ore deposits are very rich, thus compensating for lack of depth or magnitude

When molybdenite is to be concentrated it is better to crush the ore with rolls than with stamps, as the latter have a tendency to create an abnormal amount of slime which the rolls avoid to some extent.

The Secretary of the Interior, in September 1899, decided that a patent may issue covering both quartz and placer claim, this decision reversing that previously made by United States Land Commissioner Best.

Good-sized pine trees will grow up, in 25 to 40 years, on an area over which the trees have been cut, in the Western states, but the timber is not so suitable for mine use as the older trees of the previous growth.

Ore-cars having side latches are not usually so well liked for underground work as those fitted with end latches. The side latches occasionally catch on timbers when passing, particularly in mines where the ground is heavy and the timbers shift.

The handling of ore or waste underground by means of wheelbarrows, is seldom economical. It usually involves many short delays, and the amount of material that may be moved per barrow is relatively small, and consequently expensive.

Antimony usually occurs as the sulphide, stibnite, but also occasionally in native state. There are several California localities where native antimony has been found, among them San Emedio canyon, in Fresno county, and near Corona, Riverside county.

Steel winding ropes rarely can withstand a tension on the wires collectively equal to the aggregate strength of the single wires. A rope was broken, under test, by a pull of 250 tons, whereas the aggregate strength of the individual wires comprising the rope was 320 tons.

The export of metallic copper during any particular month does not necessarily indicate the consumption of the metal during that or the succeeding month. Often large quantities of copper are bought on speculation. Not infrequently copper bought by speculators is transshipped several times.

The safe load that may be placed on beams of Oregon pine can only be determined when the dimensions of the beams, and the distance between the supports are known. Engineering books, like Trautwine and Kemp, give tables by means of which the required information may be worked out.

It is neither customary nor good practice to roast ore that is to be concentrated, as better results can be had with the raw ore. Some gold ore difficult to amalgamate, owing to presence of some deleterious substance, such as molybdenite, graphite, talc, or some other mineral with a greasy, unctuous feel, may in many cases be concentrated to advantage.

The stock of any corporation organized under the laws of California is assessable, no matter what promises or explanations are made by promoters. Mining and other corporations organized under the laws of other states and doing business in California are subject to the laws of this State.

Many do not know that some of the great copper mines of Bingham, Utah, were, at one time, lead-silver producers, the copper ore coming in at greater depth. At the junction of the Galena and Jordan veins, in the early history of that camp, over 100,000 tons of lead-silver ore were mined, producing $2,000,000.

Where the owner of a mining claim allows another to operate his property under bond, and the owner places a notice on the claim, stating that neither he nor the property will be responsible for the debts contracted by the operator, no labor liens or attachments can be legally placed on the property.

The gold-bearing quartzite of the Battle Mountain district above Leadville is at the same geological horizon as the quartzites lying under the Leadville silver-lead orebodies. These mostly occur in limestone, but little effort is made in Leadville district to prospect for gold, outside of the porphyry area back of Breece hill.

Mufflers to minimize the noise of the escape of exhaust steam from high-pressure steam engines are sometimes needed. A good muffler is made by inserting, near the engine, a chamber of 15 or 20 times the volume of the cylinder and continuing the exhaust pipe from this chamber. This will do away with the disturbance caused by steam passing through a tortuous exhaust pipe.

To avoid the operation of the mechanic's lien law upon mines in the state of Nevada, the statute requires that the owner or person in charge shall post a notice within three days after he shall have had information of any construction, alteration or repairing, stating that he will not be responsible for the same. This notice must be posted in a conspicuous place on the mine buildings, or at some place where it can readily be seen.

There is no hope of finding either oil or coal in andesite. Rocks of this description are of volcanic origin, and while occasionally small pieces of carbonaceous matter are found in andesites, these are probably due to the carbonizing of trees and pieces of wood which became involved in the molten rock. There are numerous occurrences of these carbonized fragments buried in andesite at Virginia City, Nev., and at Bodie, California.

A good mine track for light traffic, where car and load do not exceed 2,000 lb., is made by placing a 2 by 4 scantling on edge, on ties which are notched to receive the scantling and held in place by wedges. The scantling is then faced with strap-iron ⅛-in. thick and about 1¼-in. wide. In some mines where there are two tracks in the main gangway, or adit, the outgoing loaded cars run on T rails, and the incoming empties run on a track built as above described.

The only way in which the rainfall of a place may be ascertained is by actual measurement, by means of a rain-gauge. These cost little, consisting of a metal vessel of given standard dimensions and a glass-gauge, on which are marked the proper graduations. The gauge, being of smaller diameter than the can into which the rain falls, gives a column of greater height, making the measurement easier and accurate. Evaporation must also be determined by actual measurement of the decreasing height of a column of water in an open vessel of uniform cross-section.

Mortars of stamp-mills should be anchored securely to mortar-blocks, to prevent their shifting. This may be accomplished by first securing the anchor bolts in the blocks. There are two methods in common use. First, holes are bored through a solid block and pockets cut in the sides at points corresponding to the lower ends of the bolts. Into these pockets are inserted heavy cast-iron washers of suitable shape and the bolts are passed downward through the auger-holes and heavy nuts screwed onto the threaded bolts. A better way is that of building up the mortar-block with two-inch plank. While the block is in course of construction, either on the surface or in the pit, the anchor-bolts are laid in, eyes having been turned on the lower ends by the blacksmith. Holes of proper size are bored horizontally through the block in a transverse direction, and directly opposite the position of the eyes on the anchor-bolts. Through the eyes, connected by the horizontal bore-holes, heavy bars—usually of railroad iron—are passed, and the block is then completed by spiking on the remaining planks, generally two courses. The upper ends of the bolts are in place and when the mortar is lowered onto the block it can be firmly screwed down. The bolts cannot turn where those with eyes are used, and the mortar may be held perfectly rigid by keeping the nuts tightly screwed up.

The pressure of the wind on a tramway, building or other structure, varies nearly as the squares of the velocities. Thus, a wind blowing at 20 miles per hour exerts a pressure of two pounds per sq. ft., while a wind with a velocity of 40 miles per hour causes a pressure of about eight pounds per sq. ft. The pressure on a broad surface is probably greater per square foot than on one of smaller area.

The United States Geological Survey announces that during 1905 there were produced in the United States 35,246,812 bbl. of cement, valued at $33,245,867. The use of cement is constantly increasing, and the material from which it may be made is abundant in certain localities. Excellent cement has been made from calcareous travertine as well as from pure limestone mixed with the proper amount of clay.

When a hillside, by reason of the large amount of clay present, causes landslips, this tendency to unstability may sometimes be largely overcome if not prevented altogether by driving adits into the hill and draining off the water which is responsible for the slips. In San Bernardino county, California, repeated landslips in the Cajon pass caused much delay to traffic on the Santa Fe railroad and the difficulty was overcome by making drainage-cuts, and constructing a roof over the piece of bad ground, nearly 600 ft. long and 50 ft. wide.

Large smelting furnaces can obviously be operated more cheaply than small ones. What the limit in the size of a blast-furnace is, has never been determined. Formerly a furnace 48 in. long and 36 in. wide was considered large. Gradually the size was increased until cupolas were built 2 in. or more in width at the tuyeres and 18 ft. long. Within the past year, this length has been increased and a furnace now in construction will be over 50 ft. long. Possibly this will not be the limit of length, if this huge furnace proves a success.

Much of the old machinery on the Comstock—in its day the best and most elaborate in the world—has been sold to other mines or to other industrial concerns, and some has been broken up for old iron. The hoist at one time used at the Belcher shaft was sold several years ago to an Oregon lumber company. The great pump at the Union shaft was mostly reduced to junk and re-cast into modern mining machinery. Back of the Combination shaft lies a heap of scrap-iron and steel, among which may be seen dozens of nickel-plated nuts and other portions of a mine pump. Extravagance in equipment was smiled upon, and even encouraged in those early Comstock days.

A valuable optical invention is reported by Consul-General W. A. Rublee of Vienna, who states that a Hungarian chemist, after years of experiments, has produced a fluid optical lens of great power that can be produced cheaply. A fluid substance is enclosed between two thin crystals, overcoming defects of ordinary lenses. The largest glass lens heretofore manufactured out of massive glass for astronomical purposes has a diameter of 49.2 in. and required several years, at a cost of many thousand dollars, to produce. Such a glass can now be made in a few weeks for about $500. Lenses of smaller diameter for photographic purposes and opera glasses can be procured at correspondingly low prices.

In a very steep shaft a skip may be prevented from overturning when in motion by setting the wheels on lugs projecting from plates riveted to the sides a short distance above the bottom, and placing a lug back of the side draw-bars. This permits the skip to dump automatically into the bins at the surface, but prevents it overturning backward in the shaft. Where the shaft has an incline of over 75°, it is safer to put in guide-rails either above the wheels, to prevent them leaving the track, or, better still, guides of the ordinary type. When either of these are in place, the skips can be run rapidly on either incline or curve, and almost as large a tonnage handled as in a vertical shaft.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

The Editor:

Sir—Without entering into the recent discussion on what constitutes a "true fissure vein," I would like to put in a plea for the term 'vein-zone,' as distinct from the common use of 'fissure vein,' which implies an individual vein. The vein-zone is a particular width in a mountain mass in which one or several individual veins may occur, or in which for intervals there may be no vein proper at all, only the barren habitat for veins. This zone may be one formed by, and occupied by, the line of principal faulting or crushing in the upheaval of the mountain mass. It is a zone of fault-breccia and slickensides; and it may range from a width of a few feet up to one hundred feet or more. It may contain one prominent vein or several minor veins, or for intervals there may be no vein at all, only barren slipped and crushed country rock. To illustrate, I recall a prominent calcspar and quartz vein that outcropped boldly on the crest of a mountain composed of thin bedded limestones and slates, and which for some little depth was very productive of rich silver-lead ore. Then it ceased. A long cross-cut was driven at the base of the mountain to cut the vein in its entirety at greater depth. But no vein was found, no quartz, calcspar, or ore, only a vein-zone a hundred feet wide of barren fissures with slickensided walls and breccia. The zone was there but not the vein; such as it was, it represented the central axial line of crushing and faulting in the mountain, which was folded into an anticline. At another place the vein-zone was more limited in width and consisted of a series of fractures with corrugated slipping planes and breccia, cemented by carbonaceous material or graphite, and with many so-called walls that faded gradually into the country on either side the principal crushed zone, containing the ore deposit. In this vein-zone there might also be long intervals in which there was neither quartz nor ore.

It not infrequently happens in certain regions of Idaho, in corrugated limestones and slates, that strong outcrops of quartz and of calcspar occur near the surface rich in ore, and miners, running a long cross-cut into the base of the mountain several hundred feet below that outcrop, are disappointed in not finding the vein and still go on, claiming it is shifted by a fault or change of dip or the like. In many such cases they have cut the vein-zone where it ought to be and they have not known it. The so-called 'true fissure vein' or single individual lode between two defined walls is by no means so common and normal an occurrence of ore deposit as the vein-zone.

ARTHUR LAKES.

Denver, June 12, 1906.

THE JURY SYSTEM AND MINING LITIGATION.

The Editor:

Sir—A question of much moment to the miner, in common with persons in other lines of business, is the manner in which conflicting claims are adjudicated in our courts. The matter of trial by jury, and the retaining of this old system of trials, has been discussed in all its bearings by many of our most eminent men, both legal and lay, but at present it would seem that no consensus of opinion exists. The question remains open.

The point of most interest to mining men is whether it is the system best calculated to determine, with absolute impartiality, the respective rights of litigants and whether or not it best conserves the interests of all concerned. It is the purpose of this letter to provoke discussion upon a subject fraught with much importance to all engaged in the mining business; if it arouses any interest among your many readers and stimulates a ventilation of the ideas involved, some good may be accomplished.

Has the average juror a proper sense of the responsibilities of his position and has he a clear apprehension of the duties devolving upon him, both legal and moral, when sitting in judgment at a trial? I venture to answer this negatively.

For the purpose of argument and to support the contention that the average layman doing jury duty does not fully realize the great, even solemn duty that devolves upon him in that capacity, let us for a moment liken him to a voter at the polls. We know that in this case it is too often true that the main issues are lost sight of or ignored and that many votes are influenced by considerations of a personal character; in short, it is more frequently a case of choosing what is expedient rather than what is right.

Is it not true that many men, when being examined in regard to their qualifications to sit as jurors in a case, answer the questions satisfactorily and yet have in their hearts a lurking prejudice against the one side or, in default of this, some degree of sympathy for the other? It may be argued that the same may be said in regard to the Court itself, but this does not hold true, for many reasons. The juryman fills a judicial office but a short while—a few days or weeks at most—and then goes back to his place in the ranks; he has no judicial reputation to make or maintain; if he is in sympathy with either litigant—or, what practically amounts to the same thing, prejudiced in any way—if he is not thoroughly imbued with a sense of his responsibility, he is very liable to allow his decision to be warped and swayed by personal feelings.

The judge, on the contrary, cannot afford to do this; he is elected or appointed to administer the law as he construes it; he has his reputation at stake; if he errs in any way he is liable, either to ridicule on one hand, or a reversal by an Appellate Court on the other. It is not a pre-requisite in a juryman that he have a knowledge of law; that is stated by the Court; the only function of a jury is to bring in a verdict in accordance with the law as enunciated by the Court, and the evidence as adduced at the trial. This brings into play the reasoning faculties of the juror; and that different lines of reasoning are indulged in by almost as many different persons, the average verdict amply proves. It would appear, therefore, that the personal equation is an important factor in the present jury system. That jurors are not always governed by their oath in these matters, is a fact so well known that it almost seems unnecessary to try to prove it—but I will cite just one case of which I happen to have personal knowledge.

A mining suit was tried before a jury in one of our district courts a few years ago. The suit was brought by a mine-owner to recover from a lessee the share of the proceeds of the ore mined, which plaintiff claimed was rightfully his under the terms of the lease. According to one clause of the agreement, the lessee was to pay royalty only on ore that went over a certain grade. The lessee owned and operated his own reduction plant and it was made clear at the trial that he had mixed in sufficient waste rock with the ore in mining it, so as to keep the grade below the royalty point; consequently when the treatment charges (which were high) were paid, there was nothing coming to the mine-owner. Although fraud was clearly proved at the trial, yet the sympathies of the jurors were so overwhelmingly in favor of the defendant that they brought in a unanimous verdict in his favor.

Many cases of a similar character might be cited in this connection, but it is not necessary, nor is it germane to my present purpose to enter into a discussion of many other features of the jury system such as expense of maintenance, difficulty and delay in securing jurors, etc. The question before those engaged in the mining business resolves itself to this: Is the system the best one that can be applied in order to obtain a just determination of the rights of the litigants, and would anyone be liable to injury were it abolished and mining suits tried before the Court without a jury?

In cases when the Court might desire enlightenment on obscure points that could not be made clear in the regular course of the trial, a commission might be appointed, either by the Court itself or by stipulation of parties. This should consist of men competent to deal with the points in question, who could give the matters at issue intelligent investigation and bring in their findings to the Court, thereby elucidating it and facilitating a decision. On account of the very nature of things, one of the parties is sure to feel aggrieved when the decision is announced, and in that case he has his means of redress, as under present conditions, in appeal to a superior court. There the whole matter is taken under review and the Court, without any assistance from a jury, will pass upon the case according to its merits, so that no one's interests are ultimately jeopardized any more than under the present jury system, which is unwieldy and unsatisfactory in many ways.

EDWARD W. RALPH.

Butte, June 28, 1906.

Copper Statistics.—L. Vogelstein & Co., of New York, give the figures of the German consumption of foreign copper for the months January-April, 1906, as compared with the same period of time for 1905 and 1904:

	1906	1905	1904
Imports	42,946 tons	32,172 tons	40,859 tons
Exports	4,142 "	4,413 "	2,651 "
Consumption	38,804 tons	27,759 tons	38,208 tons

The Leonard Head-Frame.

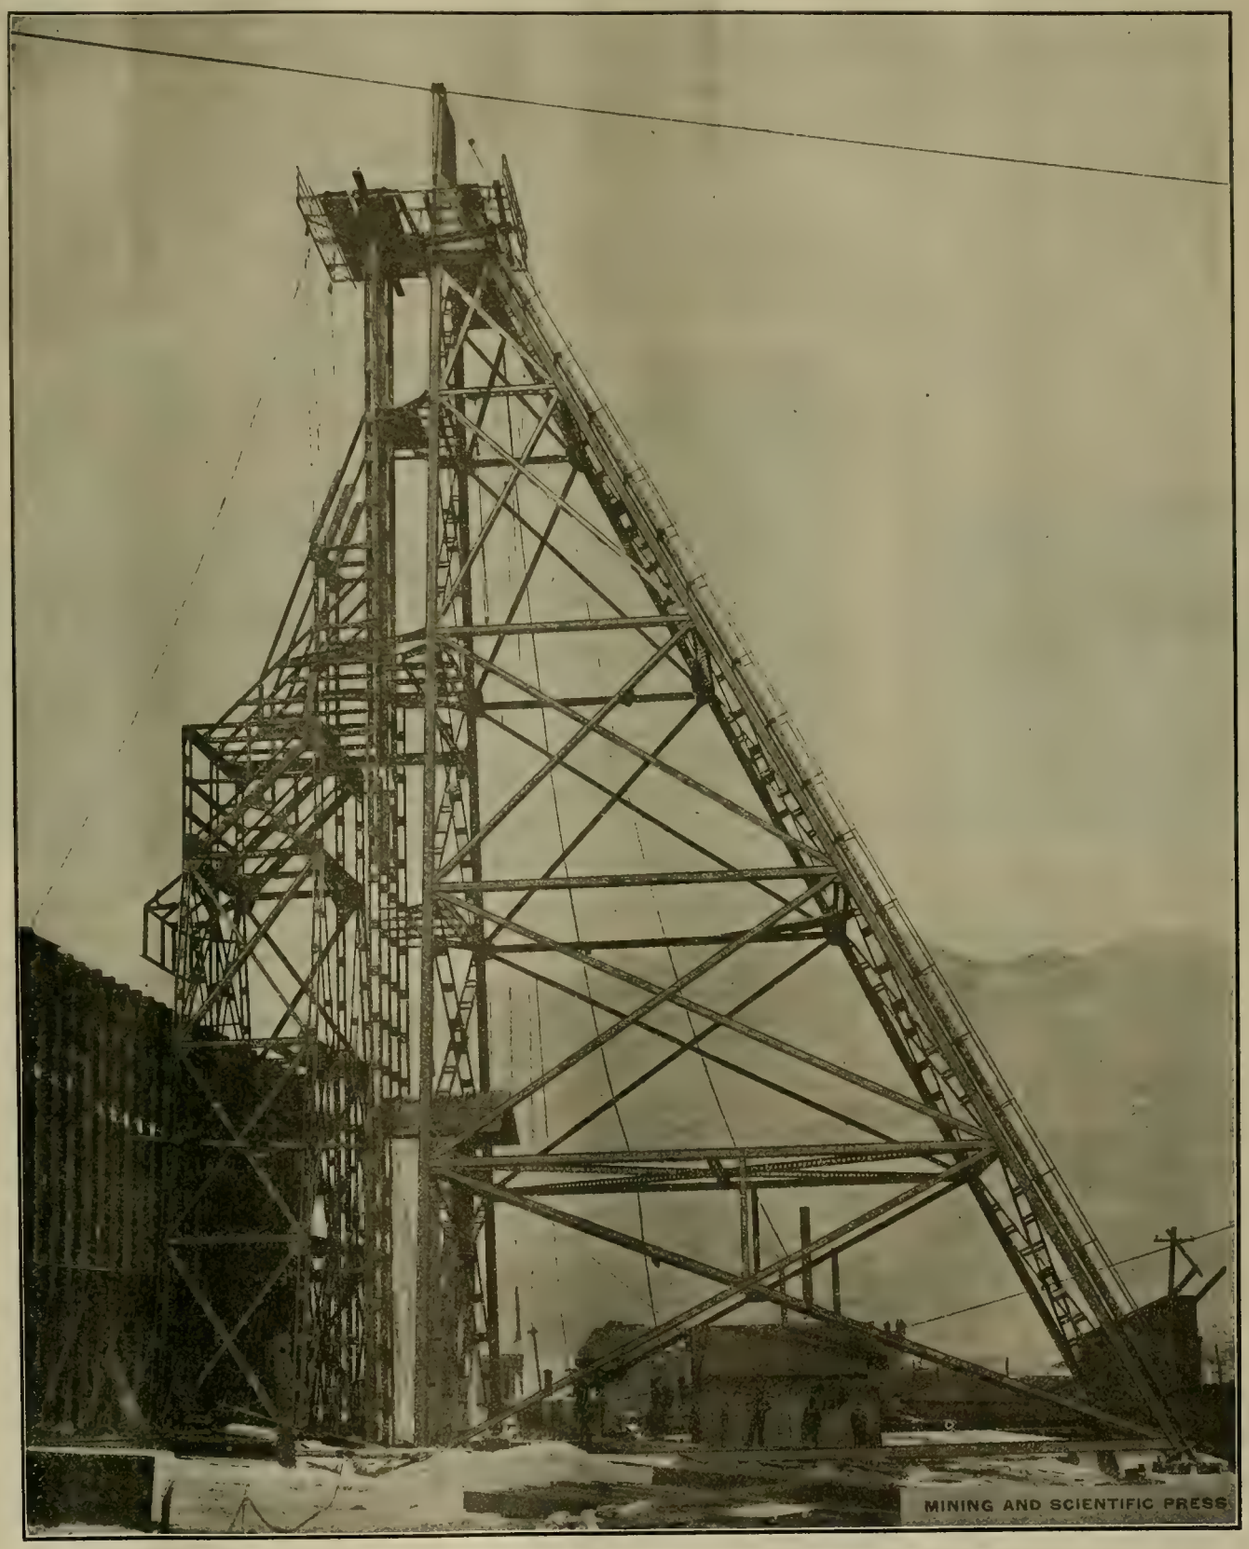
Written for the MINING AND SCIENTIFIC PRESS by A. H. HALLORAN.

The Boston & Montana Copper Mining Company, of Butte, has recently erected a steel head-frame at the new Leonard shaft. As the old Leonard shaft was taxed beyond its hoisting and pumping capacity, raises were run from the 500 and 1,200-ft. levels under a shaft that was 300 ft. deep; sinking from the bottom of this and raising from intermediate levels has made a four-compartment shaft, 1,200 ft. deep, that is to be used in hoisting all the Leonard ore. The new head-frame illustrated herewith embodies the most modern ideas in steel construction and is designed to give maximum strength with a minimum of material. The members have all been calculated to withstand the stresses due to load and the strains due to vibration. The estimated force-resultant falls just within the base of the inclined member. In comparison with frames on other Butte mines, it is both lighter and stronger. From the collar of the shaft this head-frame rises 140 ft. to the centre of the sheaves and 152 ft. to the top of the frame, the whole being surmounted by a 40-ft. flagpole. The two sheaves are 12 ft. diam. and will carry 1½-in. round cable. The base is 47 ft. 6in. by 68 ft., exclusive of the guide-frame and ore-bins. The main members are built up of two 12-in. channels and 1⅜ by 16 in. cover-plates outside, and lattice-work inside. The guides are of steel and are designed to sustain no great weight. The structure is cross-braced throughout to withstand vibration and other strains. Concrete piers form foundations for the frame and ore-bins.

The skip-dump and bins contain several novel features. The ore is to be hoisted in skips, automatically dumping into the skip-bins, from which it is drawn into a 10-ton electric tram-car which runs on a track over the railroad bins and distributes the ore to them. The skip ore-bins are 14 ft. long, with inclined floor giving a capacity of nearly 150 tons. The railroad ore-bins are 26 ft. wide and 150 ft. long, with a capacity of 3,000 tons. The ore from the skips is dumped into skip-bins by a swinging chute. Air-lifts are used on all the dumping gates. The dumping level of the skip-bins is 75 ft. above the ground, that of the railroad bins 50 feet.

In the lower part of the skip-bins is the apparatus for changing from skips to cages. In hoisting ore, a five-ton skip with a single-deck cage above is to be used, in lowering men four-deck cages will be employed. A radial swinging guide can be opened in the guide-frame, allowing the skips or cages to be swung into their respective pockets marked by the stationary guides. This is automatically controlled by air-cylinders and latches, allowing the change from one to the other to be made in less than three minutes by one man. The skip is attached to hoisting rope by clevis and king-bolt, the bolt being chained to the rope to prevent danger of its falling. The gallows-frame was designed by L. T. Sicka and is being erected under the supervision of Fred Brule. The labor and material are furnished by the American Bridge Company. Hoisting will be done with a Nordberg engine with 32 by 72-in. cylinders and carrying 1½-in. round cable, good for 3,500 feet.

Electrical engineers in the direction of the larger apparatus factories are all of the mind that the tremendous demands for copper in 1907 will doubtless cause an advance of prices for lake and electrolytic that will make present quotations seem low. American manufacturers of electrical supplies find by studies of plans decided upon in North America and Europe for hydro-electric power and railroad and telephone installations in 1907 that the volume will be largely in excess of the contracts awarded in the last eighteen months. In hydro-electric power transmission undertakings alone, that have been determined upon for construction in Europe and America during 1907, statistical engineers estimate that 175,000,000 lb. of copper line material will be required. Switzerland is planning the nationalization of her sources of water power in order to electrify her railways. Italy, in pushing Genoa to be the first port of the Mediterranean, is going to add largely to her electrified roads. Germany, France, Austria, Belgium, Holland and Great Britain are about to begin electrical engineering works of great magnitude. The London county council has decided upon building fourteen great electric power installations, and the amount of work coming on in North America is astonishing electrical engineers. Telephone engineers at home and in Europe are all certain that 1907 will break all records for the consumption of copper wire.



THE LEONARD HEAD-FRAME.

The Imbert Process.

Written for the MINING AND SCIENTIFIC PRESS by E. GIBBON SPILSBURY.

Anything in the way of a new smelting process for the production of zinc from its sulphide ore is apt to be looked upon with considerable distrust by metallurgists in general. There is no other metal in commercial use which offers so many difficulties in its production, and certainly few branches of metallurgy have had more money invested unprofitably in endeavors to improve it.

Notwithstanding all these efforts, the only practical dry process in use today is the same which was evolved some seventy years ago, of distilling the oxides of zinc by means of direct contact with carbon in closed retorts. All efforts so far to make a radical change in this smelting process have turned out failures, chiefly owing to the fact that zinc vapors, especially in their nascent state, have such an extreme affinity for oxygen, that not only must they be protected from contact with the atmosphere, but also from the presence of carbonic acid, which they readily decompose at a temperature of 600° C.

It is readily understood that these peculiarities absolutely prohibit the use of any open combustion methods of reduction, such as any form of blast-furnace or reverberatory hearth. All the necessary heat for the distillation must therefore be passed through the shell of the retort. In order to remove all oxidizing reagents, it is necessary thoroughly to roast the sulphides before charging the ore in the retorts, and thus convert them into oxides. To again reduce these oxides, a considerable amount of fuel is required, which takes up much room in the retort, so that the average amount of ore which can be charged at a time is not over sixty pounds.

The volatilization temperature of metallic zinc is between 950° and 1000° C, but the temperature of the reducing point of zinc oxide by carbon, is from 1250° to 1300° C. It is a pretty well understood fact that the reduction of the oxidized ores is produced mainly by the actual contact of carbon, and not alone by CO. Nevertheless considerable CO_2 is bound to be formed and therefore it is necessary to remove the Zn vapors as rapidly as they are generated to a temperature lower than 600° C so as to prevent their re-action on the CO_2.

It is readily seen from the above that the metallurgy of zinc is not only a complex but also a delicate operation, and that any discovery which would tend to simplify and lessen the manipulation in the process would be a great benefit to the trade. The latest improvement in this direction is the invention of a French engineer, Antoine Henri Imbert, of Paris, who has patented a process for the extraction of a certain range of metals from their sulphides. An understanding of the theory of his process may best be had from his own description in his patent application.

Copper is well known to act as a very energetic desulphurizer toward most of the ordinary metals. In particular, if copper be mixed with blende or with galena or with a mixture of these two sulphides, constituting a complex ore, and if the proportions taken be such that the whole of the sulphur is combined with the copper, the other metal or metals being liberated, then on the mixture being suitably heated the following reaction will be set up:

$$ZnS+2Cu=Cu_2S+Zn, \text{ or}$$
$$PbS+2Cu=Cu_2S+Pb, \text{ or again}$$
$$ZnS+PbS+4Cu=2Cu_2S+Zn+Pb.$$

Generally speaking if M be taken to represent the metal whose affinity for sulphur is inferior to that exhibited by copper, the reaction

$$MnS+2n'Cu=n'Cu_2S+nM$$

will take place.

The next stage of the process consists in recovering the copper, which as is well known may be easily effected by the bessemer process, namely by blowing air through the resulting copper sulphide. Hence the same copper may be employed indefinitely for treating fresh quantities of raw material. In practice, the following method is adopted: For the extraction of lead a mixture is prepared of coarsely crushed galena and granulated metallic copper in exact proportion to saturate the sulphur of this galena and to form copper sulphide, Cu_2S. The mixture may be placed, for example in a crucible capable of resisting the action of galena, preference being given to a graphite crucible, and the whole is heated to a relatively low temperature, about 800° C. The method employed for treating blende is exactly the same, and at the commencement of operations the reactions are identical. The blende, which by itself is almost infusible at a very high temperature, fuses readily in presence of copper at a temperature approaching 1000°. Between 1100° and 1200°, the zinc escapes from the molten mass with great rapidity and under violent ebullition, and may then be condensed (preferably to the molten state) by any known means.

The same procedure may be adopted with a complex mineral containing zinc and lead in any relative proportions whatsoever. The same phenomena occur, but at temperatures varying in accordance with the predominance of one sulphide or the other. If care be taken to protect the lead which accumulates at the bottom of the crucible from exposure to the greater heat necessary for vaporizing the zinc, the contamination of the zinc vapors with those of the boiling lead is prevented. In all instances where the process can be employed, the whole of the copper introduced into the smelting bath is recovered as a residue. This copper is in the form of sulphide, Cu_2S.

Now, it has long been known that when a matte has been obtained in the treatment of copper ores it is possible by means of Manhes and David's adaptation of the bessemer process to the metallurgy of copper, to reduce the copper to a metallic state by blowing air into a molten copper sulphide remaining as a final compound after the iron has been removed by scorification at the expense of the converter lining. Therefore, by applying this method to the copper sulphide remaining as an indefinitely renewed residue of the application of the present process, the whole of the copper introduced into the initial mixture may be recovered in the state of metal.

There cannot be any appreciable loss, the copper sulphide being pure, and free from any concomitant scorification. At the same time the lining of the converter remains intact, and may be made of graphite or any material that does not react on copper sulphide. This recovery of the reagent is effected without any consumption of fuel beyond that requisite to furnish the motive power for supplying the compressed air to the converter. It is advantageous to heat the mineral beforehand in any kind of crucible or even in an open hearth reducing furnace. The output of the apparatus is thereby considerably increased with quite an insignificant increase of fuel.

From the foregoing it will be seen that the advantages in favor of the process are many. In the case of simple ores, galena or blende taken separately, these advantages are: Abolition of any preliminary roasting; the consumption of fuel is reduced to the minimum necessary for the fusion of the galena at a moderate temperature, followed immediately by the removal of the lead and the recovery of the copper. In the case of blende, the consumption of fuel is reduced to the amount required for effecting fusion at a medium temperature and maintaining that temperature during the distillation of the zinc, which is effected rapidly, the entire reaction being performed during the period of fusion. There is an important saving in the wear and tear of the vessels employed for the reaction. There is a considerable decrease in manipulation. In the case of complex ores, mixtures of galena and blende in any proportions whatsoever, there is no need for any separation of the two sulphides by hand or mechanical appliances; nor of any concentration process.

The treatment is restricted to a simple process of fusion, followed by distillation of the zinc liberated in large bubbles from the molten mass; and, finally, there is opportunity for a complete and easy utilization of ores very abundant and generally left unworked.

From the foregoing description it also follows that the process is applicable to the extraction (from their sulphides) of all metals whose affinity for sulphur is inferior to that of copper; furthermore that no special form of apparatus is necessary for carrying out the process.

The manner in which the process is being carried on at the inventor's works, at Izzy, France, is as follows: The furnace, while only an experimental one, is really a full unit of what would be the regular type in practice. It consists of a graphite retort, similar in shape to those used in gas works, but of the following dimensions: Length 3 ft. 8 in.; width on bottom 12 in., and height in center 9 in., supported back and front, in a suitable furnace, for distributing the heat equally all around the retort. The front of the retort is closed by a cast-iron fire-brick lined front provided with the necessary charging apertures and tap-hole. An opening in the upper portion of the back of the retort communicates with the chamber where the metallic vapors generated in the retort are condensed, and subsequently run out into molds.

The retort having been suitably heated, the charge consisting of some 80 lb. zinc-blende mixed with about 8% of its weight of lime, is introduced. The charging aperture is closed, and the ore is heated up to a dull red. During this period, the rear opening is left in communication with the atmosphere, to permit the escape of the vapors from any moisture as well as the water of combination in the blende. This process takes about 20 min. At the end of this time the charging door is opened and the requisite amount of molten copper is poured into the retort, which is at once closed. The heating is continued and at the end of about one hour the molten zinc begins to appear at the tap-hole of the condenser. The production during the next two hours is normally at the rate of 24 lb. per hr., and as a rule, by the end of the fourth hour from 92 to 94% of the zinc contained in the ore has been recovered.

As soon as this point has been reached, the entire charge, which by this time is in a molten state, is drawn off through the tap-hole into a suitable settling-pot, which allows the separation of the copper-matte from the small amount of slag present. This matte would in practice be passed to a small converter of the usual type and blown to blister copper, which is then ready to be used again in the following charges. As any gold and silver contained in the original ore are entirely concentrated in the copper-matte, the resulting blister copper, after a series of operations, becomes rich enough to be treated as bullion, and in that case would be replaced by fresh copper.

At the first glance, the use of a reducing agent, worth nearly three times the value of the metal to be obtained, appears open to serious objection, but when we consider that the converting of copper sulphide to blister copper, is the regular method employed in nearly all of our works for the treatment of copper-mattes, and that the copper losses by this process rarely exceed 2%, the objections do not appear so serious after all. As a fact, while the converting of the ordinary matte produced in our blast-furnaces does entail a loss of about 2% of the copper contents, it is well established that the largest amount of this loss is due to the presence of so much iron in the matte. In converting the almost chemically pure copper sulphide produced by the Imbert process, no such losses occur. The average loss established so far appears to be not over 1%, which at the present market price of copper would be less than half a cent per pound on the zinc produced.

It is of course too early to predict what effect this invention is going to have on the general metallurgy of zinc, for notwithstanding the claims made for it, it is always at best a long and tedious fight to disturb such an old established metallurgical process as that of the distillation of zinc, by the Belgian and Silesian methods. On the other hand, if the same results can be relied on in general practice, as those obtained in the unit furnace now being operated, the saving in the greater extraction alone, together with the shortening of the time required for the extraction, four-fifths nearly, will much more than counterbalance any losses in copper, and will lessen the cost of the production of spelter over ¼c. per pound.

But apart from the regular established zinc production, there is a wide field of application for this process, in the treatment of the complex ores of zinc and lead, and zinc and copper. In many places, notably in northern California, there are deposits of copper ore carrying large percentages of zinc-blende. At present this zinc is a detriment and a constant source of trouble and worry to the smelter. By the introduction of this process all necessity for the separation of these minerals is avoided, as is also any preliminary roasting. The zinc becomes an element of profit, and the ores, after its extraction, are in the best possible condition for blast-furnace treatment. The complex zinc-lead ores are especially well adapted to economical treatment by this process. Where water or other concentration methods fail, this process separates the lead and zinc perfectly, yielding on the one hand pure metallic spelter and on the other metallic lead. It is true that, in the preliminary process, the lead produced is somewhat alloyed with copper, but it is easily liquidated out, to a great extent, and the resulting crusts of leady copper are used over and over for further reductions. The treatment of antimony sulphides by this process appears to be also a great success, and to result in great economies over the present methods. Finally, while it is too early to predict with certainty just how far the benefits of this invention will reach, the practical work already done in the experimental furnace demonstrates the theoretical accuracy of the process, and also the fact that under most normal conditions, the cost of producing zinc from sulphide ores will not exceed that under the present system, and where complex ores are to be treated, a saving of 50% over the present costs may be fairly expected.

Covellite is a rare ore of copper. It is sulphide, of dark blue color, almost black. At the Rambler mine in Carbon county, Wyoming, it contains platinum.

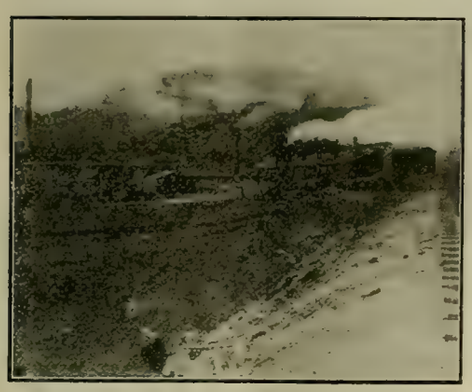
The Mount Lyell Copper Mine.

Written for the MINING AND SCIENTIFIC PRESS by
S. A. IONIDES.

The Mount Lyell copper mine is situated about 30 miles inland from the head of Macquarie harbor on the west coast of Tasmania. It was, and is still, one of the lowest grade copper mines in active operation, and for this reason, if for no other, it possesses exceptional interest and is worthy of special consideration by mining engineers. The grade of ore smelted was, a few years ago, about one and a half per cent copper, plus a small amount of silver and gold, and even now, after the absorption of the North Mount Lyell mine, the grade does not exceed 2.5 per cent copper.

The company (The Mount Lyell Mining & Railway Co.) possesses several properties within the range of a few miles of the smelter and connected with it by surface and aerial tram-lines. It has also several properties outside which will be mentioned later. The biggest orebody is a big blow of solid pyrite carrying 0.8 per cent copper and small values in silver and gold. It is worked by an open-cut and the ore conveyed over an aerial tramway to the smelter. At the present time the open-cut has been carried down to the level of the loading station of the cable cars, so an incline shaft is being sunk in the foot-wall of the 'blow' to hoist the ore to such a level that it may be trammed or sent over gravity planes to the loading station, the way in which all ore is being treated at present.

About a mile away from the 'blow' is the North Mount



MT. LYELL SMELTER.

Lyell mine. This belonged formerly to a separate company, but within the last three years it has been amalgamated with the Mount Lyell. The copper occurs here in the form of bornite, and is of much better grade than the pyrite in the 'blow.' The lode has been of variable size, pinching somewhat at the fourth level, but at the sixth a stope has been taken out to 60 ft. wide. This body is worked by ordinary underground mining methods from shafts sunk from an adit level. The ore from this mine has to be run along a steam tram-line, then down an incline by rope haulage, and again along a steam tram-line to the smelter.

The occurrence of these two deposits close to one another has proved fortunate, as they form an excellent self-fluxing mixture, needing only the addition of quite small quantities of lime and coke. The former is obtained from a quarry near the smelter and the company has its own coking works in New South Wales.

All the ore on the way to the smelter is carefully sampled. One out of every 25 buckets that go over the aerial tramway, and one out of every rake of trucks that go over the railway below the incline haulage are passed through the sampling mill, so that a reasonably accurate valuation of the ore going to the smelter can always be obtained. Just in front of the smelter bins all the ore is weighed. Each rake of trucks is weighed both on arrival and departure upon a special weigh-bridge capable of weighing ten trucks at a time. The buckets from the aerial tramway are weighed on arrival only, but their tare is checked about every ten days by weighing on departure.

The smelter is of the water-jacketed blast-furnace type, and does its work by pyritic smelting. The amount of coke used is about 60 lb. to a charge of half a ton of ore, so that practically all the heat must come from the burning sulphur. The heat at the feed-floor is with certain winds sufficient to seriously inconvenience the workmen feeding, so a few months ago mechanical feeders were being installed, in order that the men need not approach the furnace so closely.

Till about three years ago two plants were in use, each comprising five furnaces, of which four were in operation while one was being renewed. Then the addition of the North Mt. Lyell ore and the increase of the blast-pressure to 30 oz. so increased their smelting capacity that they were able to put as much through four furnaces as through eight previously, and their No. 2 smelter is the only one in operation now.

In front of the furnaces are four rectangular fore-hearths. The slag and matte together flow from one tap-hole into the first of these continuously. From the fourth the slag overflows continuously into a stream of running water, by which it is granulated and carried to a pit, in which are two centrifugal pumps. The slag and water are hoisted in these and run onto the slag dump. A by-pass is provided for occasions when one or another of the pumps must be stopped for repairs. From the first fore-hearth the matte is tapped every 20 minutes or so, and from the others a small amount is drawn three or four times every shift of eight hours.

The matte contains 40 to 50 per cent copper, and when cold is broken up and taken to the converter-house. There it is melted in a small circular furnace, and run down a movable trough to the converters. The converters are lined with silica obtained from a quarry near-by and last for six or seven charges without relining. A billet of wood and some briquetted flue-dust

MT. LYELL MINE.

are usually added to the molten matte and air blown in. Two lots of slag are first drawn off, and then the blister copper is ready to pour. The end reaction (by which the workmen tell if the charge is ready) is very sharp, and if a mistake is made, it is found out after a few pounds have been poured and air is blown in again for from a quarter to half a minute, and then the charge is ready.

The blister copper is the final product prepared at the mine, and is shipped to America for further refining and extraction of the silver and gold contents. The company has extensive machine-shops, in which all necessary castings and iron-work can be made. It owns and operates a narrow-gauge railway to Strahan, on Macquarie harbor, running passengers and freight trains. For part of the way it works on cogs on the Abt system. It has also an extensive mileage of 2-ft. gauge tram-lines for timber and mine use. Recently the company has started sulphuric acid and phosphate works in Melbourne to use profitably that part of the 'blow' which is too low-grade to be smelted for copper, and with its reserve fund it has acquired and is developing a tin property in the northeastern district of Tasmania.

At Mount Lyell itself, work has been done under great disadvantages. The early work had to be done through a dense and almost impenetrable forest covering a very hilly country. It is perpetually raining, the average rainfall being about 12 ft. per annum, and even short spells of dry weather render the region extremely liable to brush fires, and this in spite of the fact that the sulphur fumes from the smelter have practically destroyed all vegetation for a radius of six miles around.

It was decided several years ago by a Spokane, Wash., court, that the property, and not the stock of a corporation, is assessable.

The Lost Packer Copper Gold Lode.

Contributed to the MINING AND SCIENTIFIC PRESS by
E. P. JENNINGS.

This remarkable lode is situated in the Loon Creek mining district, Custer county, Idaho, 25 miles northwest of the town of Custer, and 120 miles west of Mackay, a station on a branch of the Oregon Short Line Railroad. The district was a noted placer camp 35 years ago, then abandoned until 1902, when the lode was discovered and bodies of chalcopyrite, containing 2 to 10 oz. gold were opened and shipped by pack-train and wagon to the railroad at Mackay, thence to the Salt Lake City smelters. Sufficient ore was produced in two years to pay for the development, which exposed large bodies of chalcopyrite.

The mine is situated on the southern slope of Packer mountain, which rises 2,000 ft. above Canyon creek, a small tributary of Loon creek, giving ample opportunities for exploration through adits, six of which have been driven; the lowest of these exposes the ore 750 ft. below the outcrop. Packer mountain is a complex of mica schist, knobs and bosses of granite and dikes of felsite and aplite, with its summit covered by a heavy sheet of rhyolite. This portion of Idaho is extremely rugged; the mountains having an elevation of over 10,000 ft., with deep valleys and canyons.

The lode occupies a shear-zone, which has been traced from near the bed of Canyon creek to the rhyolite sheet capping the summit of the hill, a distance of 5,000 ft., with a strike of N 5° E and a dip of 77° W; the minimum width of the lode is 30 ft.; it cuts both the granite

ANOTHER VIEW OF THE ORE.

and schist, and is faulted by the intrusive aplite and felsite dikes.

The ore is chalcopyrite, containing from 2 to 20 oz. gold and a small amount of silver. The high grade ore is compact and massive, occurring in well-defined shoots, 100 ft. long and 6 ft. maximum width, near the foot-wall; it is continuous to the lowest workings; another body of ore occurs near the hanging wall of the lode and separated from the foot-wall shoots by 25 ft. of mixed ore, schist and partially altered granite. These high-grade orebodies, averaging 15% copper, are enclosed in bodies of lean ore that are practically continuous for the full length of the tunnels and are mixtures of chalcopyrite, granular quartz and chlorite-sericite schist; the amount of chalcopyrite becoming less as the walls are approached. The narrow band of sericitic granite is intercalated between bands of schist near the center of the lode. These schist bands contain granular quartz, sericite and chlorite with small amounts of chalcopyrite.

The lode has been subjected to movements subsequent to its mineralization, both along its strike, as shown by the many slips and slickensides, particularly at the contact of the solid chalcopyrite and the low-grade ore, and also by transverse faults. A nearly horizontal felsite dike 20 ft. thick displaces the ore five feet to the west, between the second and third levels; a short distance below this dike two faults occur nearly parallel to it, these also displace the lode a few feet to the west. The lode is also faulted by two aplite dikes; one near its north end with an east-west strike that displaces it 20 ft. to the west, and the second, several hundred feet south of the first dike, that has a strike of N 20° E; the last mentioned faults both the lode and the horizontal felsite dike five or six feet.

The following minerals have been recognized in the lode: Gold and silver-bearing chalcopyrite, bornite, native copper, quartz, sericite, chlorite, barite, calcite, with malachite stains, hematite and limonite in the zone of oxidation. Pyrite, an almost universal lode mineral, is absent.

The zone of oxidation is 30 to 40 ft. thick, resting

directly on the unaltered sulphides that present no evidence of secondary enrichment except the occurrence of thin coatings of bornite in a few places and metallic copper in the quartz ore near the crossing of the aplite dike. Erosion has closely followed the weathering of the lode on this precipitous hillside; this in connection with the compact nature of the ore and lode-filling, is unfavorable to secondary enrichment.

The axes of the ore-shoots coincide with the principal shear-planes; the ore completely replacing the original granite, which may have been crushed by the formation of the shearing fractures, forming deposits of compact chalcopyrite. On either side of these shoots and separated from them by post-mineral slip-planes, the rock is more or less impregnated with chalcopyrite. Thin sections of this material show grains of quartz enclosed in sericite with chalcopyrite in irregular masses disseminated through the sericite and penetrating seams in the quartz. The quartz is evidently an original mineral of the granite and the sericite an alternation product of the feldspar. Thin sections from different portions of the lode and the granite walls exhibit abundant sericite and small amounts of chalcopyrite, the amount of the latter depending on its position in regard to the principal fractures.

The action of the mineralization processes was of too short duration to completely mineralize the shear-zone and a complex vein resulted, with the principal mineralization along those fractures that offered the least resistance to the solution. There is no evidence that any portion of the lode was an open fissure; it is a replacement of the more highly brecciated portions of the shear-zone, with an abundant formation of sericite replacing the feldspar and ferro-magnesian minerals. It can be classed with those metasomatic deposits of the sericite, copper-gold type, as described by Lindgren.

I infer that the formation of the shear-zone and its mineralization followed closely the granite intrusion, and that thermal waters, representing the last phase of the vulcanism that produced the intrusions of granite, were the mineralizing agents. The nature of these solutions is doubtful, but from the amount of sericite formed, they must have been rich in potassium salts, and contained gold, silver, copper, iron and sulphur; but they were deficient in silica, unless this substance was held in solution by an excess of potassium carbonate and deposited in the upper portions of the lode which are now eroded.

The remarkable features of the lode are the absence of all primary sulphides but chalcopyrite; the scarcity of secondary or vein quartz and all common gangue minerals that are directly precipitated from mineralizing solutions. The quartz present was undoubtedly a constituent of the original granite and the chlorite and sericite are derived from the hornblende and feldspar of the same rock. The later eruptives had no known effect on the mineralization beyond an increase in the gold content of the ore near the felsite dike, but their mechanical effects are shown by the numerous faults, slips, and schistose structure of portions of the lode.

My deductions are based on observations made during a brief visit in 1904, supplemented by information concerning later developments furnished me by John P. Boyle, superintendent of the mine, and L. Webster Wickes, mining engineer, and I also extend my thanks to both gentlemen for samples of ore and lode material.*

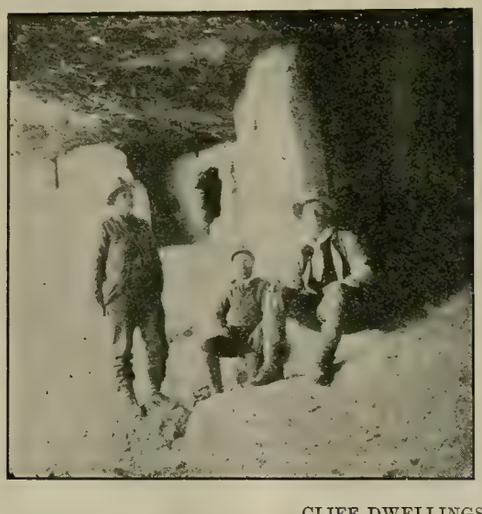
*This paper was also read before the Quebec meeting of the Canadian Mining Institute.

In the Aros Region, Mexico.

We are indebted to Mr. F. A. Stearns for the accompanying illustrations and notes concerning ancient dwellings near Chuichipa, in Sonora, Mexico. The cliff dwellings are in caves halfway up the mountain and overlooking a steep ravine; they are so arranged as to give protection from assault. Those shown in the photograph contain 19 compartments, the outer walls being pierced with port-holes through which a spear could be thrust so as to reach an intruder and hurl him 50 to 70 ft. down the face of the cliff onto the sharp rocks below. The doors are all constructed in the shape of the letter T, with a wide space for the shoulders and a narrow one for the feet, so that anyone entering had to bend to the knees and thus expose himself to a blow at the hands of the defender. The Aros river drains this region, which abounds in steep and picturesque ravines. While snow still lingers on the summits of the hills, the valleys contain palms and flowers in tropical luxuriance. The region contains many ruins of old patios and gardens; also abandoned mine workings, some of which may prove worthy of exploration.

THE VALLEY OF THE AROS RIVER, MEXICO.

A REST HOUSE.



CLIFF DWELLINGS IN SONORA, MEXICO.

Opal Mining in Australia.—The White Cliffs opal field is having a steady output of the better grade. One gem, obtained six feet from the surface, weighed 13 oz. and realized $500. The opal miners claim that the price for the gems is controlled by a ring, and that in consequence fair value is not obtained. The Opal Miners' Protective Association will therefore appoint an agent, to be sent to Germany and America, and will open up show rooms in Chicago for the display of polished opals.

The Prospector.

Enquiries sent to this department are answered free of charge, if submitted by subscribers who are not in arrears. The full name and post-office address of the sender must be given, otherwise no answer will be made. Those who are not subscribers must accompany their questions with a fee of $3 for each question. No assays are made.

The rock from Spokane, Wash., is: No. 1, Granodiorite.

The rock from Kingman, Ariz., marked No. 14, has every appearance of hornstone, veined with chalcedony, but the flaky brittle mineral is softer than typical hornstone. It is a very unusual rock, and this determination is not final.

The rocks from Florence, Idaho, were determined as follows: No. 1 Quartz with clay, stained with copper carbonate; No. 2 Quartz with limonite (iron oxide); No. 3, a metamorphic aggregate consisting chiefly of Quartz and epidote (the green mineral), with a little iron oxide.

The two rock samples from Eureka, Nev., marked T.P. are the variety of silica known as semi-opal, and are of no value except as specimens.

Copper ore occurring in schist or in eruptive rocks usually concentrates readily by ordinary wet methods, but the value of the concentrate depends upon the original character of the ore. Thus, bornite contains a higher percentage of copper than chalcopyrite. The amount of iron sulphide present also has a direct influence on the grade of concentrate as well as the perfection of concentration.

Submarine Drilling.

By E. P. Schaefer.

The conditions under which submarine rock excavation must be done are extremely difficult, calling for special apparatus of unusual strength and endurance. This character of work is nearly always carried on where tides, currents, winds, and storms are present in varying degrees, and these elements are antagonistic to economical and rapid work, and until recently involved such uncertainty as to require absolute daring to undertake river and harbor excavation; but, add to these troubles, deep water, irregular bottom, covered with mud, sand, or other shifting material which fills in almost as fast as removed, and a combination of difficulties results which, hitherto, has been considered almost insurmountable.

Owing to the increasing submergence of both ocean and lake-going vessels the removal of subaqueous material is daily becoming a more important feature. The deepening of channels is possible only because of the improvements which have been made in rock-drills, and today such work may be done effectively, rapidly, and cheaply. In modern submarine drilling, steels are used anywhere from 30 to 60 ft. in length and sometimes they weigh as much as 400 lb. To use them effectively even in hard homogeneous material is a problem; in poor material and under water, where the drill must be run by the sense of feeling, difficulties are multiplied, so that it is absolutely essential to have a drill which is at once massive, powerful, durable, and capable of perfect control through all ranges of length of stroke and weight of blow. The drill must, of course, be mounted on a barge or float, fitted with suitable framing to support the guides, the drills, the boilers and other auxiliary apparatus. The barge is towed into place and anchored by means of cables, anchor-chains or spuds, or a combination of these methods, depending upon the rise and fall of the tides or the currents to be encountered.

SUBMARINE DRILLING ON THE CLYDE.

In the accompanying illustration is shown one of the two barges which are, at present, working on a rock-blasting contract at Renfrew, near Glasgow. The work to be done consists of drilling, blasting and removing rock for deepening the channel of the river Clyde. Many thousands of holes must be drilled, the average depth of each being about eight feet. Occasionally, however, the bed of the river is such that a depth of ten feet becomes necessary and this drilling must be accomplished through a maximum depth of 30 ft. of water.

Each barge is provided with eight Ingersoll-Rand rock-drills. The drill used has a diameter of five inches and a length of stroke of eight inches. The drills take steam from two marine boilers at either end of the barge. They are connected to a main steam-pipe which runs behind the drills, and from which branch pipes, fitted with stop-valves, are taken. The drills are connected with these branch pipes by means of steam-hose. Immediately below the stop-valves are hand-winches which are used to feed the drills to the work or to raise them from it. The drills are supported in guides and suspended by wire-ropes which pass over pulleys at the top of the frame and under pulleys at the bottom, thus allowing a very accurate feeding of the machines. Behind these winches is a secondary and smaller winch provided with a wire-rope to hoist the drill-steels from the holes and replace them preparatory to drilling. The winches and the handles of the stop-valves are in close proximity so that one man can handle each machine.

The submarine tubes which are used in this contract consist of long lengths of four-inch screwed piping which may be extended to meet the rise of the tide. These tubes are forced through the overlying mud and sand to the rock-bed and serve to keep the advancing hole free from extraneous matter. The holes are drilled exactly as in the case of drilling down-holes on land, the drill being fed down as far as possible, then run back, a longer steel inserted, and so on, until the desired depth is reached, when the steel is removed and the hole charged with explosive through the tube. The casing tube is then removed, the wires connected with the blasting battery and explosion effected without shifting the barge.*

*Abstracted from 'Compressed Air.'

A Vale of Sinaloa.

In a recent issue of 'The Evening Post,' New York, Mr. Courtenay De Kalb, a well-known mining engineer writes a charming description of a valley in Sinaloa, Mexico. He says, in part:

Bacubirito enjoys a setting of exquisite beauty as first seen from the heights south of the great bend of the Sinaloa river on which the city stands. Its white buildings, and the tall, white, graceful spire of the mission church of San Pedro, in the midst of a spreading green valley, stand out in brilliant, cameo-like relief against the deep blue wall of the Sierra de Ocorahui, the first of the mighty ridges which mount ever higher to the region of labyrinthine canyons and snowy summits in the Sierra Madre. It is a beautiful picture, and arouses expectations which are not realized on entering the town. The church, though simple and inexpensive, is a model of elegant form, far surpassing anything that would be found in communities of 3,000 people in the United States. The early Spanish missionaries carried with them, and taught in enduring monuments, a fifth gospel of architectural beauty. How far they may be credited with the cultivation of artistic appreciation in other directions it were not easy to answer. That they taught the rudiments of many arts we know, but something must be allowed to the native tendency of the Mexican Indian to express himself in esthetic form, else it would be difficult to account for the rare modeling and wood-carving that one so often finds among the rude dwellers of the hills who have not even had the opportunity of seeing the prototypes of their own artistic creations. So strong is this tendency that one of the difficulties which the American constantly encounters in directing labor in Mexico is to prevent his carpenters, masons, and machinists from expending undue time in the refinements of detail. The Mexican reaches out after beauty as the flower does after light. He ornaments his person, and bears his finery with grace. He turns his saddle and bridle into works of art; the common arriero's mule-brushes are things to delight the eye by their form and color; when he fences in his cornfield he weaves patterns of beauty with his wattles twisted from post to post; he sleeps on a 'petate' woven with artistic designs. The spirit demanding that his works of utility shall combine a charm for the eye extends everywhere even to the humblest laborers. The factory and the impatient utilitarian foreigner are fast crushing out the expression of this feeling for beauty, and in the name of progress the Mexican may lay aside the arts of his childhood, and, hanging up his guitar, become songless and money-getting; or he may grasp at the culture of civilization behind the first wave of financial development that is rolling in upon his country, and find better and larger means for revealing the soul and talent that lie in him.

Eastward from Bacubirito is a maze of mountains, carved out of the western edge of the elevated plateau known as the Sierra Madre, interspersed with pleasant valleys, so deeply cut by ages of erosion that the semi-tropical climate has been carried back in long lanes from the lowlands of the coast, giving rise to the oft-repeated phenomenon of canefields and gardens luxuriant with bananas and papayas (the 'melon-zapote' of Mexico) surrounded by towering mountain walls leading within rifle range of pine-clad summits that invite the winter snows. In this region are mining districts still celebrated, like that of San Jose de Gracia, and the multitude of copper-gold veins being developed promises a revival of mining on a large scale. Through Bacubirito once passed the commerce of the great mines of Trigo, and a considerable portion of that of the world-famous mining town of Guadalupe y Calvo, as well as that of the once noted Guadalupe and San Manuel gold mines at La Cunibre de San Manuel, a district again attracting capital from England and the United States. The copper mines of Mapiri, and the gold placers of the Descubridora arroyo at the very doors of Bacubirito, are also contributing to brighten the future of this decadent foothill city

Nickel Production.—According to a report prepared by A. P. Coleman for the Ontario bureau of mines, the only real competitor of Ontario as a nickel producer is the French penal colony, New Caledonia. Though the United States has dropped out of the race as a producer of nickel ore, it is still one of the most important countries for the refining and utilization of the metal nickel, much the greater part of the Canadian metal being treated at Constable Hook, New Jersey.

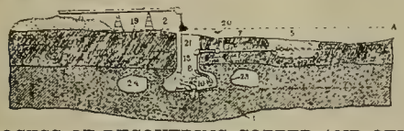
The Sudbury nickel field has long been known as the most important source of that metal in America, if not in the world, but the work of the last three years has brought out more and more strikingly the unique character of this mining region. It has been proved that all the ore deposits of economic importance are at or near the outer margin of a huge laccolithic sheet of intrusive rock a mile and a quarter thick, 36 miles long and 17 miles wide. This sheet is now in the form of a boat-shaped syncline, with its pointed end to the southwest and its square end to the northeast. The rock composing this sheet is norite at the outer and lower edge, merging into granite or granodiorite at the inner (upper) edge. The orebodies are round the margin of the norite, or along dike-like offsets from it, and have evidently segregated from the rock while still molten, though they may have undergone later rearrangement by circulating water. In a chapter devoted to the uses of nickel it is pointed out that Switzerland, Austria-Hungary, and France within the last few years have adopted pure nickel instead of the nickel-copper alloy for their coinage. The pure metal does not tarnish or change color, but keeps bright and attractive, and, as it is harder, the imprint stands wear much better. It is more difficult to counterfeit, since the minting requires more powerful presses. "Why," asks Mr. Coleman, "should not Canada, the producer of half the nickel of the world, replace her ugly cents by clean, untarnishable nickel coins, almost as handsome as silver and much more durable?" Canada is to have a mint, and it should begin its work by coining 1-cent and 5-cent pieces of pure nickel, making use of a distinctively Canadian metal. The nickel production of the Sudbury field for the calendar year 1904 is given as 4,729 tons, valued at $1,513,280, and the total production of the district since the discovery of the nickel deposits there up to and including the year 1904, at 43,877 tons, valued at $12,660,069.

Mining and Metallurgical Patents.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

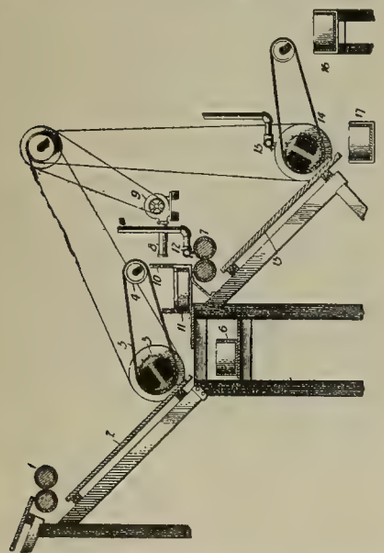
APPARATUS FOR MOVING AND MINING MATERIAL OF A GRANULAR AND COMMINUTED NATURE, No. 821,372. A. McDougall, Duluth, Minn.

In an apparatus for raising valuable material which lies in a layer at considerable depth below a layer of valueless material, the combination of the layer of valueless material having an opening therethrough and exposing the layer of valuable material, the said layer of valuable material having a chamber formed therein, and a sump within the chamber, columns or pillars sustaining the roof of the chamber, a reservoir formed on the layer of valueless material, a pipe or pipes connecting said reservoir and passing through the layer of valueless material and entering the chamber within the layer of valuable material, means for directing a stream or streams of water from said pipe or pipes against the valuable material, a lift pump or pumps within the chamber and having its or their inlet or inlets within the sump and discharging out through the opening in the layer of valueless material upon a dump formed upon the layer of valueless material, and means connecting the dump to the reservoir whereby the same water may be used for disintegrating the valuable material, carrying it in suspension to the sump and discharging it to the dump.



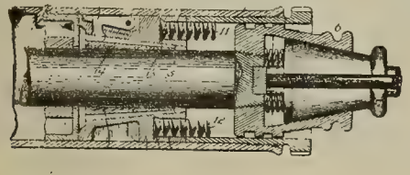
PROCESS OF RECOVERING COPPER AND OTHER VALUES FROM CERTAIN ORES, No. 821,516. T. J. Lovett, Chicago, Ill.

The herein-described combined dry and wet process of concentrating and collecting the non-magnetic sulphide and contained values in low-grade chalcopyrite ores carrying a material percentage of magnetic iron, which consists of the steps of coarse-crushing the ore in a dry state to reduce the sulphide and iron and allow of the dislodgment of adhering sulphide powder, magnetically separating from the dry reduced mass the disunited iron particles, dislodging from said dry iron particles and collecting the adhering sulphide powder, comminuting the remaining attracted material in a wet state to a degree of fineness which disunites the remaining iron particles from the other constituents, magnetically separating the disunited remaining iron particles from the wet mass, and finally collecting and saving the sulphide concentrates from the recrushed mass.



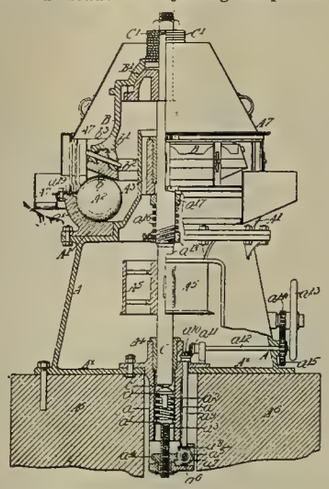
BEARING FOR ROCK-DRILLS, No. 821,325. T. E. Adams, Cleveland, Ohio.

A bearing-sleeve of low-carbon tough steel having a threaded exterior and having interior grooves, and also having a hardened interior face, the hardened portion confined to the portions of the interior face between the grooves.



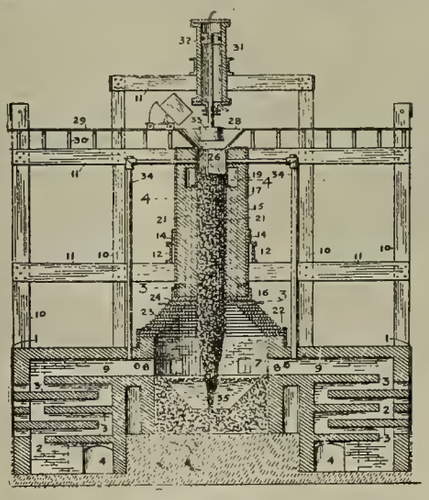
CRUSHING OR PULVERIZING APPARATUS, No. 821,421. W. Kitto, Barnes, London, England.

In a ball crushing-mill, the combination with a ball-raceway, a vertical driving-shaft extending through said raceway, and a bell-shaped ball-propeller driven by said shaft; of a resilient footstep for said shaft, a piston or platform vertically adjustable in said footstep and on which the lower end of said shaft directly rests, a spring interposed between said shaft and said piston, an adjustable buffer and means for adjusting the piston.



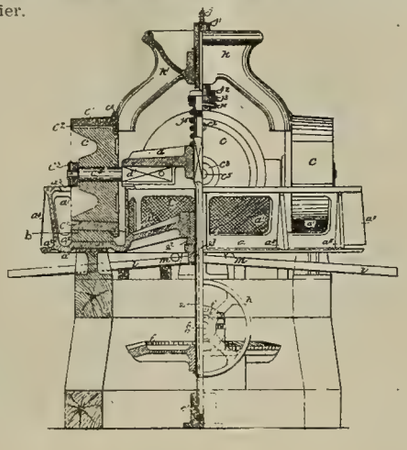
APPARATUS FOR SMELTING ORES, No. 821,190. J. A. Potter, San Francisco, Cal.

In an apparatus of the character described, the combination of a smelting-chamber having an open hearth, a conduit arranged to conduct products of combustion over said hearth, a retort-chamber over said hearth, open at bottom, whereby the material discharged from said retort-chamber descends into said hearth, and means for feeding the material into said retort-chamber.



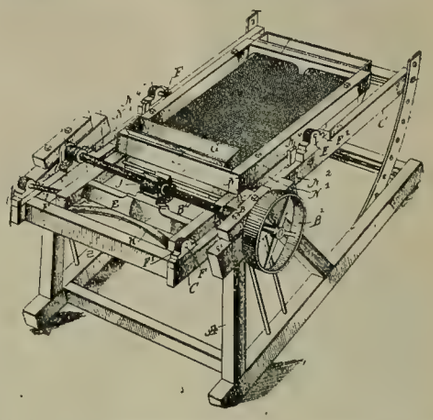
MACHINE FOR CRUSHING AND AMALGAMATING METALLIFEROUS ORES, No. 822,052. Hiram Jones, Ascot Vale, Victoria, Australia.

A machine for reducing ores comprising an annular trough, an inclined circular die therein, said trough having discharge-openings on both sides of the die, crushing-rollers running on said die, a central rotating shaft, a carrier mounted on said shaft and having vertical movement thereon and coupling-pins connected to the rollers and having pivotal movement in the carrier.



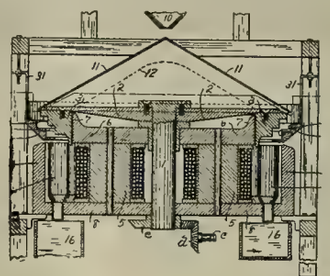
ORE-SEPARATOR, No. 821,430. Albert Perry, Caribou, Col.

A separator comprising a main frame, inclined radius-rods fulcrumed on the said main frame, an inclined swing-frame hung on the said radius-rods, a screen supported on the said swing-frame, a leaf-spring secured at its middle on the upper end of the said swing-frame, links pivotally supported from the said main frame and pivotally connected with the free ends of the said spring, a shoe on the upper end of the said swing-frame, a revoluble cam engaging the said shoe for imparting a downward-and-forward swinging motion to the said swing-frame and its screen, bumping-blocks on the sides of the main frame, adapted to be engaged by blocks on the sides of the front end of the swing-frame on the upstroke of the latter, a feed-hopper secured to the upper end of the screen, a concentrate-receiving hopper attached to and arranged under the screen, and a tailing-hopper at the lower end of the screen.



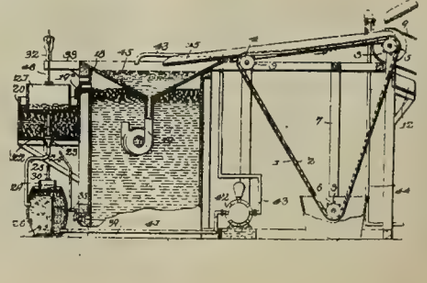
MAGNETIC SEPARATOR, No. 821,615. Myron Dings, Milwaukee.

In a magnetic separator, the combination of an upwardly-extending driving-shaft; a non-magnetic support mounted to rotate with said shaft; a magnetizable ring connected with said support; a set of magnets, arranged with cores parallel to the shaft at a less radius than that of said ring; segmental upper pole-pieces symmetrically balanced, and extending outwardly into close proximity to the inner faces of said ring; segmental lower pole-pieces of opposite polarity extending outwardly and upwardly into proximity to the outer faces of said ring; inclined non-magnetic shields extending downwardly and inwardly between said pole-pieces; and chutes extending from the lower ends of the shields downwardly through suitable apertures in the lower pole-pieces.



ORE-SEPARATOR, No. 822,515. Fred B. Finley, Los Angeles, Cal.

An ore-separator comprising a tank provided with an outlet-valve, a combined hopper and coil mixer arranged within the tank, a second tank into which the first tank discharges, a third tank into which the second tank discharges, a float-operated valve in the second tank for controlling passage of oil to the third tank, a valve in the second tank, a rock-beam, a connection between the rock-beam and the float of the second tank and the valve of the first tank, and means for supplying classified gangue and oil to the hopper.



Special Correspondence.

LONDON, June 13.

A leading event last week in the world of mining was the death of Sir Charles Tennant at the ripe age of 82. He was in the true sense a captain of industry. Besides being member of Parliament for one of the Scottish divisions between 1879 and 1890, he was chairman of most of the following companies and a director of all of them: The Union Bank of Scotland, the North British and Mercantile Insurance Co., the United Alkali Co., the Tharsis Co., the Assam Railways and Trading Co., the Linlithgow Oil Co., the New Cycle Co., and the Forth Bridge Railway Co. Of the Indian gold mining companies he was chairman of the following: Mysore (until within a few months of his death), Champion Reef, Balaghat, Coromandel, Gold Fields of Mysore, Kolar Mines Power Station, Road Block, and Sudan Gold Field. Having been one of the earliest and most persistent supporters of Indian gold mining, he reaped a rich reward. It is said his dividends from this source alone brought him an income of from £30,000 to £40,000 per annum.

The directors of The Zinc Corporation, Ltd., have issued their first half-yearly report to February 13, 1906. The Company was formed for the purpose of acquiring a large tonnage of mill-tailing, and the option of purchasing further quantities, under contracts made with four large Broken Hill mines. The Company has acquired the right to use the Potter process for the recovery of zinc, lead and silver, this process having been definitely proved to be successful on a large commercial scale. An option has also been secured giving the right to use the Elmore and Cattermole processes. The selection of the Potter process was determined chiefly because of its being advanced so far beyond the experimental stage, and because it possesses certain advantages of simplicity in working and low capital expenditure for the installation. The plant is working satisfactorily, and is now treating about 60 tons per day. Preparations are now being made for the addition of a ball-mill and other crushing appliances, and in a short time the capacity will be sufficient to deal with the whole output of tailing from the British Broken Hill Proprietary mine—about 2,000 tons per week. The directors state that they have concluded a satisfactory contract for the sale of zinc concentrate with Messrs. Aaron Hirsch and Sohn, the contract providing for the sale of from 10,000 to 20,000 tons of zinc concentrate during the current year, from 20,000 to 40,000 tons during 1907, and 40,000 tons per annum for the years 1908 to 1911, both inclusive.

The erection of a large central concentrating plant is receiving attention. A site for the same has been selected adjoining the South Blocks property, and orders have been placed for all the heavy machinery and plant. A good start has been made with the erection of a sulphuric acid plant, sulphuric acid being essential for the economic working of the Potter process.

The question of erecting zinc smelting works is also having attention, and in this connection the services of Mr. Augustin Queneau have been secured to go into the whole matter and report fully on same. This gentleman has been chosen by Mr. H. C. Hoover—one of the directors. Previous to this, Mr. Queneau had filled the position of consulting engineer to the New Jersey Zinc Co., at New York. The Zinc Corporation Ltd. started with a cash capital of £260,000.

At the third Ordinary General Meeting of Esperanza Ltd., the chairman, Mr. A. P. Hillier, gave an interesting retrospect of the Company. He said it was registered as recently as October, 1903, and has thus, up to the present time, had an existence of a little more than 2½ years. During that period considerably more than the entire capital of the Company has been paid back in dividends, which to date have amounted to 120%, or 24s. per share; and in addition to these handsome dividends, the directors of the Esperanza Mining Co. have been able to create a substantial reserve fund. The phenomenal increase in the prosperity of this Company may be said to have commenced with the development of the west sulphide veins, to the discovery of which attention was drawn at the last annual meeting. The shipping of ore from these veins began in February of last year, although it was not until July that it was mined in any large quantities, and the returns received by the Company from the smelting of this ore have produced results of an extremely satisfactory character. The gross receipts for the year ending December 31, 1905, amounted to £1,027,377, of which £584,643 was net profit. No other gold mine in the world, the chairman thought, had produced, during that same period, either more bullion or more profit. And at the present time the Esperanza continued, so far as he was able to ascertain, the greatest gold-producer in the world. He said the profits during the past six months would have been considerably greater even than they have been, were it not for the difficulty of obtaining a sufficient number of railroad cars to carry the ore to the smelters. The difficulty has arisen with the Mexican railways, which have been unable to meet the demand of the mine for cars. Turning to the future of the mine, the chairman stated that in his opinion its prospects appear to be of a most promising character. In the discussion which followed the chairman's address, a shareholder gave utterance to the time-honored plea on behalf of the London stock market for equality of opportunity with New York as to current information from the mine, and the chairman promised that in addition to the card giving the monthly results a quarterly progress report should be sent to the shareholders.

Notwithstanding the drop in tin (which a wag attributes to the lessened demand caused by the canned meat scare) Cornish mining 'setts' are said to be in great demand. It is rumored that Great North Downs and Wheal Peevor together with Wheal Rose will probably be worked with a capital of £100,000. These concerns are on the St. Aubyn estate. Thevool, near Grenville United, is mentioned in the list of likely starters, the capital named being £70,000. It is said that the following mines will be worked by a syndicate: Wheal Fortune, North Prosper, Wheal Crabbe, Wheal Virgin, Gwallon, Wheal Hampton, Tolvaddon, Wheal Caroline, and Owen Vean; that a license of the Wheal William, in the Luxulyan district, has been granted to a London syndicate; that four more setts have been acquired by the directors of Wheal Vor—Wheal Metal, Carleen, Polladrass, and Great Wheal Fortune; and that Penhale mine, Breage, will start at once. A scheme is also suggested in connection with the unwatering of Gwennap United mines. It is proposed to form a "pumping company," whose work it will be to unwater these mines, and then hand over the dry setts to new companies, the initial expenses being paid by the newcomers, and also a royalty being paid for pumping charges during the time the setts are being exploited for minerals. It is said that Wheal Geevor, St. Just, has been sold to a London syndicate, to be worked with capital of £40,000. The mine was formerly known as North Levant, and it is near the famous Levant, which is worked far out under the bed of the Atlantic, and which, from 1820 to date, has yielded profits considerably over £1,500,000 sterling. North Levant, or Wheal Geevor, stopped operations about a decade ago, at which time tin was only £40 per ton. It is only about 130 fathoms deep.

The statement made in Parliament by the Under-Secretary for the Colonies—Mr. Winston Churchill—that there is no general desire of the coolies employed on the Rand to leave their work and return to China, created something like a panic amongst the more extreme section of his followers. But the admitted fact that the famous repatriation proclamation, posted in Chinese at all the mines, has only resulted in 12 Chinamen, out of the many thousands employed, applying for permission to be transported back to their own country, has helped to calm the troubled breast of the shareholder in Kaffirs, and the record output of the Transvaal for the month of May of 461,202 oz., valued at close upon two millions sterling, should also tend to cheer his heart.

JOHANNESBURG, May 21.

A last effort was made by the mines to prevent the posting of the repatriation notices in the Chinese compounds. A test case, tried before the Supreme Court in Pretoria, was made by the New Kleinfontein gold mine. The decision of the Court was that the action of the Imperial Government was quite legal in offering to repatriate coolies desirous of returning to their native land. After this decision there was no alternative, so the notice was put up in the compounds. However, the action of the Chinese has been most gratifying. So far the offer has been practically ignored. A few coolies have signified their desire to return to China, but I doubt whether the total applicants will number fifty. This is about one-tenth of one per cent of the total number of coolies on the Rand. The danger from the poster is now practically over.

The mining industry should now have a period of six months' freedom from political disturbances. The next troubles start when Responsible Government is granted the Transvaal. Then the question of Chinese labor will be definitely settled. Meanwhile the feeling is more hopeful, now that it is seen that the coolies will not take advantage of the offer of repatriation. The agitation that took place over the posting of the notices was quite justified. It showed to the Liberal Party the indignation created by their policy of interference. Possibly this agitation will prevent further interference, which this blessed Party no doubt had in mind.

The market remains lifeless. If this depression continues there is no doubt that many of the shares will fall to a figure low enough for an investment. Heretofore most of the dividend payers of the Rand have stood at far too high a figure, from an investment point of view. The depression in the market valuation of shares has been enormous during the last eighteen months. This is a sign that people are ceasing to look upon Rand shares as speculations, but are considering them as investments.

For some time past, there has been a red-hot discussion on the Rand, regarding the policy of central administration in the management of mines. There has been a general expression of opinion that there is too much interference with the man on the spot, the mine manager, by the men in the head offices. As a result of the numerous letters and discussions, the system of central administration has been much modified, and in the future the mine manager will have far more authority than in the past. A group where central administration was carried very far is the General Mining & Finance Corporation, under the technical control of Messrs. G. A. and H. S. Denny. It is interesting to note that after a long trial of the system, the General Mining & Finance Corporation has given up the central administration idea, and the Dennys have left for pastures new.

An interesting excursion to the Victoria Falls is being taken by the members of the Chemical, Metallurgical & Mining Society. The May meeting of this society will be held within sound of the roar of the mighty waters. About 80 to 100 members and their friends went on this excursion. These outings to Victoria Falls are becoming quite popular in South Africa.

CANANEA, Mexico, June 20.

El Pinito mine, situated in the Magdalena district, State of Sonora, about 35 miles from the border, has taken a new lease on life. Two years ago the company operating it became involved in several lawsuits which resulted in the mine being shut down until two weeks ago. The company is composed of Washington people and the new manager is Lewis Randall. Under his supervision, the mine is being cleaned out and the 50-ton mill put in working order. The wagon-road, which cost about $15,000, is also being repaired and within a few weeks the mine will enter the producing class again. The return from the first month's milling was $40,000 from 1,500 tons of ore, and it is expected to beat this as soon as the mill starts running again.— The Cubana Mining Co. is ready to ship. This is a copper-silver property and is situated in the district of Arizpe about 110 miles from the American border. The stock in the company is owned by California people and the officers connected with the mine are also California people. The line of the Cananea, Rio Yaqui & Pacific Railroad will pass within a short distance of the mine, and as soon as the road is completed the management will ship daily 200 tons of ore running about eight per cent copper and carrying about 20 oz. silver. As the mine stands at present, there are 2,000 ft. of development work done, which shows up about 100,000 tons of ore.— The Cerro Blanco mine, 50 miles west of Cananea or about 70 miles from the American border, has been sold by the owner, H. C. Hazeltine, to an English company for $250,000. The English company, which will be known as the Cerro Blanco Mining Co., Ltd., of London, will commence operations at once and will make every effort to maintain a handsome production.— The Santa Rosalia mine, 12 miles northwest of Arizpe, is being rapidly cleaned out and preparations are being made to begin production. This mine is owned by George Mitchell and associates of New York, who bought it for $10,000. The mine is an 'antigua' and was recently re-discovered from the old Spanish records, where it is spoken of as being one of the richest gold mines in northern Mexico. The Spanish workings are 480 ft. deep with 500 ft. of drifts still in good shape. Ore running over 700 oz. gold and 1,000 oz. silver has been found on the old dumps and in the drifts. Machinery has been ordered for the property and it will be installed as soon as the mine is ready.

The Oro Maximo and Picacho mines are ready to produce. These mines are owned by the Oro Maximo Mining Co. and the El Picacho Gold Mines Co., both

companies being owned and controlled by the Clancy Bros. of Detroit. The managers expect to maintain a steady production of 100 tons daily, making a total of 200 tons. The Oro Maximo mill, which has a capacity of 200 tons, is being removed to the mine, about 40 miles southeast of Cananea. It is expected that the mill will make its first run in August. The development work on the Oro Maximo is being conducted in two shafts, one a three and the other a two-compartment shaft, and sinking is going ahead at the rate of four feet per day. Air-drills are used exclusively in the Oro Maximo and are being installed at the Picacho mine. This mine was recently bought from the Phelps-Dodge Co. by the Clancy Bros. and the work they have done on the property proves that they made a good bargain with the original owners. In the new shaft on the Picacho, ore running as high as $20,000 per ton has been found and the vein has widened to six feet at the 45-ft. level. There are over 400 men employed on the properties.— The Southwestern Mining Co., which controls the Ortega mine situated about six miles south of Cananea, is pushing work on the property and is putting on more men every week. The main development shaft, which is an incline, has run into ore running 10% copper and 18 oz. silver. This is in a drift at the 100-ft. level and where the ore is 40 ft. wide. The main shaft is down 200 ft. and has run into copper sulphide ore.— Ore running 600 oz. silver and carrying a high percentage of lead and copper is being shipped from the Alacran mine of the Arizpe Mining Co. The mine is situated in the Manzanal mountains about 17 miles from Cananea and the ore is packed about six miles to the main Arizpe wagon-road. It is the intention of the company to ship one carload of ore per week. Beside this mine, the Palo Seco, owned by the same company, is soon to enter the shipping class. The development work has shown that it is a copper mine of great promise, there being an immense body of low-grade copper-silver ore and quite a large amount of high-grade native copper.— La Chispas mine is again bonanza. This mine was one of the most famous under the Spanish regime and had a record of producing about $6,000,000 for less than 5,000 ft. of work. It is now owned by a French and American company with offices in New York, known as the La Chispas Gold Mining Co. The work done shows over $2,000,000 worth of ore in sight and the monthly shipments average a net return of about $85,000. The ore averages 18 oz. gold and 3,780 oz. silver per ton.

The Greene Consolidated Copper Co. has fully recovered from the strike which cost the lives of about 75 Mexicans and five Americans, and shut the entire plant down for three days. Outside of the time lost, the only other injury to the company was at the lumber-yard, which was burned by the strikers at a loss of $125,000. Despite rumors to the contrary, the mines and reduction plant were not injured in the slightest owing to the fact that they were well guarded. The entire mines and reduction division are being worked to their fullest capacity at present and it is predicted that the loss of the three days will be fully made up before the end of June. Beside the above company, the American mine, the Sierra de Cobre and the Cananea-Duluth were shut down for the three days of the strike, the agitators having forced the miners to go on strike against their will. These mines are in the Cananea district and employ about 500 men. The outlying camps, from that of the Southwestern Mining Co., which is only six miles from Cananea, to those of the Oro Maximo and Picacho companies, which are over 40 miles away, were not inconvenienced in the least by the strike. In fact, in most cases, the news of the strike did not reach them until it was all over. There was no trouble whatever and none of these mines lost a day.

BUTTE, June 24.

The new Davis-Daly Estates Co., which has given a contract to the Original Mining Co. to run a cross-cut 3,800 ft. long from the 1,800-ft. level to the Original mine south through the claims of the Davis-Daly Co. lying south of the Original and Parrot mines, is also planning to run another drift, 2,000 ft. northwesterly from the Original into the Mt. Moriah mine, another of its properties. Through the contract with the Original Co., the Davis-Daly Co. will be able to do in six months what otherwise would require three years. The Davis-Daly Co. expects to begin this work in a few weeks, and hopes to be able to produce 2,000 tons of ore daily within a year or eighteen months. The company has secured a site for a smelter on the Big Hole river, southwest of Butte, and a large plant will be erected there. The North Butte Co. has installed its new hoisting engine and made several trial runs without cable attachment. It will be ready for hoisting about July 1. The company is at present hoisting 850 tons of ore per day. With the new engine the output can be increased to 1,200 or 1,500 tons per day. Instead of cars and cages for hoisting, skips of four tons capacity will be used. The company has, for months, been opening its orebodies and blocking them out for rapid mining.

The East Butte Extension Mining Co. has purchased all the machinery and surface plant of the Columbus-Butte Co. at sheriff's sale, securing a $10,000 plant for about $1,200. The machinery has been moved to one of the Extension shafts where it is being installed. The Extension Co. is making regular shipments from two of its shafts. Sinking is in progress at the three other shafts.—For some time the Butte & Bacorn Co. has been hampered in shaft sinking by soft ground, but its three shafts are now in hard ground and better progress is being made. The shaft on the Colleen Bawn is down 145 ft., that of Belinda 160 ft., and the Calumet 150 ft., all timbered. The Calumet is the only one of the three that is in a vein. Talc, brecciated granite, quartz, and some iron are coming from the bottom. An effort was made to cross-cut to a vein at the 100-ft. point in the Colleen Bawn, but the ground was so soft that the cross-cutting endangered the shaft and the work had to be stopped to save the shaft. Another cross-cut will be started at a greater depth in firm ground. The company is sinking the Colleen Bawn shaft while the Belinda and Calumet are being sunk under contract. The new air compressor at the Belinda has been placed and is ready for use. The company's third hoisting engine, ordered two months ago, has also been delivered.—The shaft of the Butte Hill Copper Co., being sunk west of the Butte & Bacorn, has reached a depth of 200 ft., where a station is being cut preparatory to cross-cutting. The shaft is in the vein and peacock copper has been coming from the bottom.

A streak of good copper ore has been cut in the shaft of the Greenleaf, being sunk by the Boston & Montana Co. on the east side of the Butte district. Adjoining the Greenleaf, the Butte Copper Exploration Co. has reached a depth of 660 ft. in its shaft on the Six O'Clock claim. It will be put down 1,000 ft. before any cross-cutting will be done. Still eastward, and adjoining the Six O'Clock, the Butte & London shaft is down 400 ft., 175 of which are in bedrock. The new equipment for the mine is rapidly being put in shape. To the northwest, a short distance, are the properties of the Butte-Milwaukee Co., which are being developed by eastern capitalists.—On the west side the Butte Copper Mining Co. is making rapid progress in opening orebodies in the Trifle and Anselmo claims, both old properties. The mines lie on the strike of the vein on which are located the Rarus, St. Lawrence, Anaconda, Never Sweat, Original and Gagnon claims. The mines of the Butte Copper Co. lie just west of, and adjoin, the Gagnon group of the Trenton Co.—Nearly all of the Amalgamated companies are engaged in opening new mining ground, sinking shafts and developing their properties. The shaft on the High Ore mine, owned by the Anaconda Co., has reached a depth of nearly 2,400 ft. At that point a large station will be cut and drifts and cross-cuts run to open the ore-bodies for stoping. Connections will also be made with the other hill mines. The Anaconda Co. is also making preparations to resume mining in the Pacific and Poulin mines, which were shut down many years ago. They will be worked through the shaft of the Buffalo mine, which has heretofore been used by the Raven Co. for working its Snoozer mine. The Raven is likely to be compelled to sink a shaft of its own, although it has a promise that the Anaconda Co. will hoist its ore under contract as soon as the Buffalo shaft is operated again. The Raven has only a verbal lease on the Buffalo shaft, but the notice from the Anaconda Co. that it intended to use the shaft, came as a surprise. Since then the Raven mine has been shut down. It had been shipping 130 tons of ore per day before the shut-down. The Snoozer is one of the best new mines in the district. The Red Metal Co. owns a small interest in the mine, but that company's relations with the Raven have been entirely amicable.—The Parrot Co. is sinking the Parrot shaft deeper and has also started to reopen the Little Mina mine, the shaft of which will be sunk several hundred feet deeper. The Mina has not been worked for several years. The Parrot Co., in opening a new body of ore on the 1,800-ft. level of the Parrot mine, has again increased its daily output to about 500 tons.—A new shaft is being sunk on the Tramway mine by the Red Metal and Butte & Boston jointly, which when completed, will be used by both companies. Both own interests in the Tramway and Snohomish mines, and the Red Metal owns the Minnie Healey, which adjoins the Tramway and Snohomish. The Minnie Healey shaft, which for some time has been in bad shape, will no longer be used as a working shaft, but the three mines will be worked through the new Tramway shaft which will be sunk to a depth of 1,800 ft.—The Original Mining Co. has ceased shipping ore to the Washoe smelter, the entire output of the Original mines, about 900 tons per day, being again treated at the company's smelter in Butte.

The new hoist at the Cable mine has been completed and equipped with cages. Ore is now hoisted by cage instead of by buckets as formerly. Operations at the mine and mill were hampered last week owing to bad weather and slush in the water ditch. The mine is in good condition and is yielding the usual quantity of gold ore. The placer drilling machinery, which was stuck in the mud near the mine for several weeks, has been placed in position and the Cable Consolidated Co. will, in a few days, begin prospecting its placer ground, of which it owns more than 400 acres. If the results warrant it, the company will put in a dredging plant.— The East Butte Copper Co. is negotiating for the lease or purchase of the smelter of the Pittsburgh & Montana Co. If it succeeds in getting it, the plant will probably be re-built and used for treating the East Butte Co.'s ore exclusively. The company expects to increase its output to such an extent in a few months that additional smelter facilities will have to be obtained. The output at present is being treated at the Washoe smelter, but the capacity of the latter is taxed. The East Butte is also negotiating for additional ground adjoining its present holdings.—The Butte Central Copper Co. has sunk the Ophir shaft to 400 ft., adding 105 ft. last month.—The Lewisohn General Development Co. is sinking a new shaft on the Montgomery claim on the east side of the Butte district to catch the vein recently opened in the Birtha mine, which lies to the north of the Montgomery. The company is also exploring the 200-ft. level of the Altoona, where cross-cuts are being driven. The company will thoroughly explore the mines it has under option in the district southeast of the Butte.—The Lexington Mining Co. which, for years, was worked by lessees at considerable loss, and which a few years ago passed into the control of F. A. Heinze, has made a report to the tax authorities that has surprised them. It was the general understanding that the Lexington was costing a lot of money without producing anything, but the report shows that the net earnings for the year ending June 1, amounted to $149,986, the gross proceeds being $505,062. According to the report, there were mined during the year 33,095 tons of ore and the gross yield per ton was $15.26. The cost of mining was $6.50 per ton, transportation 36 c. per ton, and reduction $3.86 per ton. The total cost of mining was $215,282, freight $12,013, reduction $127,779. The gross yield per ton is exceeded by only one other mine in Butte, and that is the North Butte, which reports gross yield per ton at $21.11. The next highest is reported by the Boston & Montana Co. at $12. The Lexington ore yields zinc, silver and copper.—The Pittsburgh & Montana Co. also made a report during the past week, which shows a loss in operation during the year of $260,811. Its figures are as follows: Tons of ore extracted, 26,195; returns on matter shipped, $21,211; returns on blister copper, $300,220; returns on 4,172 tons of ore shipped to the Washoe smelter, $39,013; total receipts, less $6,729 paid for freight on copper, $353,716. Expenditures: Stoping, $105,596; development, $318,871; equipment, $19,609; smelter operation, $163,242; smelter equipment, $7,209; total expenditures, $614,528.

The Original Mining Co. of W. A. Clark is on the Gagnon vein to the eastward, and from a depth of 1,900 ft. the Original is hoisting 42% copper ore. West of the Gagnon the vein runs through the property of the Butte Copper Company.

The East Butte Extension Mining Co. has purchased all the machinery of the Butte-Columbus Co. and has placed it at its several shafts. A 120-h.p. boiler has been set at shaft No. 3 and it will furnish power for No. 2 and 3.

TORONTO, June 22.

The most noteworthy find recently made at Cobalt, is the discovery of a large vein of argentite on the McKinley and Darragh property, which is said to be the largest deposit of argentite so far struck here, containing about 87% silver. The Glen Lake Mining Co., of which R. A. Bailey is manager, has also made a strike, but the details are not forthcoming. The rush of prospectors up the Montreal river continues. The river runs in a northwesterly direction from the southwestern part of the Cobalt area, through the newly laid-out townships bordering on the Temaquami forest reserve, and all the region accessible by it is being prospected as far as Fort Matchewan and even further north. Steady work is being done on numerous pros-

pects, a comparatively short distance from Latchford, the point of departure. Many cobalt veins carrying silver are being worked, but no very rich returns are, as yet, reported. The general opinion is that more development will be needed than was required in Cobalt before these deposits become paying mines. One of the most promising localities is Portage bay, a large lake-like inlet on the east side of the river, three miles above Latchford, where several good discoveries have been made. On the Matawabika river, a tributary of the Montreal, 12 miles up, Mr. Klock of Orillia, Ont., has eight men at work on a quartz vein 11 in. wide with a copper-gold showing. Twenty-five miles up, Dr. Dakin, of Galt, Ont., has located a large deposit of copper-silver-nickel ore. Three copper veins are reported to occur here. Gasoline launches run for some distance up the river, carrying passengers and freight.

Active prospecting is also being carried on in the region southeast of the Cobalt district adjoining Lake Temiskaming. Many finds of silver, smaltite, and cobalt are reported. Silver-cobalt has been found at Point Fine, 20 miles south of Haileybury. The Department of Mines has been officially notified of the discovery of a small but very rich silver vein in Lorraine township.

Capt. John Harris, manager of La Rose or Timmins mine, Cobalt, was recently severely injured by a premature explosion of dynamite, which destroyed the sight of one eye. He is now in the general hospital at Toronto.

W. J. Hanna, Provincial Secretary of Ontario, has received a dispatch from the British Secretary of State for the Colonies asking for particulars of the recent explosion of seven tons of dynamite at Cobalt. The matter has been referred to the Bureau of Mines. S. Price, mining commissioner, has been kept very busy since his appointment, hearing mining disputes in regard to controverted claims to Cobalt locations. F. F. Lemieux has been appointed mining recorder for the Sudbury division, and C. H. Shera mining recorder for the Port Arthur division under the new mining law.

Mining operations in Eastern Ontario continue to show much activity, especially as regards mica, corundum and iron pyrite. There is a notable revival in the mica industry. The Lacey mica mine, owned by the General Electric Co. whose trimming works are at Ottawa, situated in Loughboro township, Frontenac county, is a heavy producer, employing 45 men. Three or four mica properties near Perth are also being actively worked.—The mine of the Canada Corundum Co., at Craigmont, Renfrew county, H. E. T. Haultain, manager, is yielding about 300 tons per month. There has been a considerable increase in the output of iron pyrite which is largely shipped to Buffalo to be used in the manufacture of sulphuric acid. The principal producing mines are those of the American Madoc Mining Co., near Madoc, Hastings county.—The Katharine lead mine, near Bannockburn, Hastings county, has been re-opened. The output of this mine and of the Hollandia is being treated at the lead smelter recently erected at Bannockburn.

One of the most important discoveries made for some time, as indicating the mineral richness of the region for a long distance north of the present productive area, has just been announced. A rich vein of calcite carrying galena, silver, and copper has been found on Lot 5, Concession 5, of Ingram township in the Wendigo Lake region. It averages five inches in width and has been traced for 600 ft. Several smaller leads run into it. The locality is about 30 miles north of Cobalt. Another large vein has been found at the Foster mine, Cobalt, seven inches wide and high in silver. A silver deposit recently found in Buck township yielded samples assaying upward of 24,000 oz. per ton.

SALT LAKE, June 25.

During June, 16 Utah mining companies have posted dividends aggregating $1,109,000. This includes the semi-annual and quarterly distributions of the Utah Consolidated and Daly-West. The companies and respective amounts paid by them were: Utah Consolidated, $750,000; Daly-West, $108,000; Silver King, $50,000; Gemini, $50,000; Consolidated Mercur, $25,000; Beck Tunnel, $25,000; Grand Central, $15,000; Horn Silver, $20,000; Mammoth, $20,000; Victoria, $12,500; Yankee Consolidated, $12,500; Swansea, $5,000; Sacramento, $5,000; Uncle Sam, $5,000; Utah (Fish Springs) $4,000; West Mountain Placer, $2,000.

All the surveys having been completed, the Continental Transportation Co., which has a lease on the right of way owned by the Rio Grande Western railway between Bingham Junction and Alta, will soon begin construction of a railway between the points mentioned. Rails are laid nearly all the way from Bingham Junction to Wasatch. Above Wasatch there will be some difficult engineering. The management promises to give mine owners of Alta a rate on ore sent to the Salt Lake smelters as low as that of Park City.—Five mining claims adjoining the Columbus Consolidated, at Alta, have been bonded to Joseph J. Bamberger of New York.—Fifty teams are now employed in hauling ore from the Columbus Consolidated mine at Alta, handling an average of 65 tons per day. The management claims the mine is earning $100,000 monthly.

The first report made in four years to shareholders of the Swansea Mining Co., has been issued. During that period the mine was idle about three years, but in the last year more favorable market conditions have enabled the company to operate profitably and from the 9,585 tons sold since May 15, 1905, there was derived a net profit above expenses of mining, transportation and treatment. In addition, money was received from royalties paid by lessees, making the total net result $17,836, out of which two $5,000-dividends were disbursed. The Swansea mine is situated in the Tintic district.—An option has been given on a control of the stock of the Carisa Mining Co., operating in Tintic district, on the basis of 45c. per share. The first payment is to be made in July and the last in October.—The ore shipments from the Tintic district last week aggregated 145 carloads, the shippers and amounts being: Gemini, 11; Bullion-Beck, 8; Scranton, 3; Dragon Iron, 16; Swansea, 3; Sunday, 1; Grand Central, 8; Mammoth, 20; Carisa, 6; Ajax, 2; Black Jack, 2; Centennial-Eureka, 41; Eagle & Blue Bell, 4; Uncle Sam, 3; Yankee Consolidated, 4; Eureka Hill, 3; May Day, 2; Beck Tunnel, 6; Godiva, 2.

Reports received from the Clifton district, in Deep Creek country, indicate that late developments made in the Gold Hill mine, controlled by officials of the Bingham Consolidated Mining & Smelting Co., are important. Little has been said about it, but it now seems likely that Clifton will become an important copper camp. The main line of the Western Pacific railroad, now building from Salt Lake to the Pacific coast, will run within 30 miles of the Gold Hill mine.—— Track laying on the Western Pacific west from Salt Lake is progressing. Nearly all the grading is done for 100 miles out of Salt Lake City.

The Bingham Mines Co., recently organized to operate a group of claims near the Boston Consolidated properties in Bingham, will be under the management of D. C. Jackling of Salt Lake.—— The management of the Fortuna mine, at Bingham, has decided to build a tramway to facilitate handling of ore. The line will be about three-quarters of a mile long. It is likely that the rail system will be used with electric motors.—— The York, Petro, Highland Boy Consolidated, and Red Wing companies, at Bingham, are to be disincorporated, and special meetings of shareholders have been called for July 20. These companies are now controlled by the Utah Apex and Utah Development companies.—— Lafayette Hanchett, general manager of the Boston Consolidated Mining Co., at Bingham, last week let a contract for 286 Wilfley tables for the company's Garfield mill. The plant will also contain 254 Johnston machines. On June 22, one of the steam-shovels ordered for the mine began operations, stripping the ore. This work will be continued until the mill is ready, early in 1907. The shovel will move 3,000 tons of earth daily. This is the second shovel used for mining purposes in Bingham.

The Daly-Judge Mining Co. has liquidated all its bonded indebtedness and will begin July with a surplus, it is said, of about $40,000.—— The West Quincy Mining Co., at Park City, is to undertake to prospect the property below the 400 level by means of core-drills.—— The shaft being sunk on the Magnolia-St. Louis property, at Park City, is now down over 300 ft.—— Ore shipments from Park City were reported last week to the amount of 2,080 tons, the shippers and amounts being: Daly-West, 570 tons; Daly-Judge, 564 tons; Daly-Judge (middling), 98 tons; Kearns-Keith, 82 tons; Silver King, 574 tons; Little Bell, 145 tons.

The Carbonate Hill mine, in Morgan county, of which Matt Daugherty of Salt Lake is manager, is shipping 20 tons of ore daily to the smelters. The ore is high in lead and iron, commanding a premium at the smelters. Development during the last week disclosed copper ore in the lower workings of the mine, the first strike of this kind made in that property.

It has been learned from good authority that engineers in the employ of Charles M. Schwab have been examining gold properties in the vicinity of Marysvale, Utah.

The directors of the Utah Consolidated Co. of Bingham, have posted a dividend of $750,000—$2.50 per share.

MINING SUMMARY

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—The feature of the week has been the consolidation of the Bonanza Circle companies (excepting the Calumet & Arizona) under the name of the Superior & Pittsburg Copper Co. The companies consolidated were: the Calumet & Pittsburg, the Pittsburg & Duluth, the Lake Superior & Pittsburg, and the Junction. There will be some delay in putting the new stock on the market, because the stock in the old companies was widely distributed. As the result of the consolidation, operations will be carried forward on an enlarged scale. The Copper Queen smelter is being overhauled and enlarged. When completed, the smelter will have eight blast-furnaces. There is some talk of building three or four reverberatory furnaces, but no definite steps have been taken in this direction as yet. The output from the smelter this month will be 8,000,000 lb. copper. The enlargement of the Calumet & Arizona smelter is going steadily forward. The output this month will be 5,000,000 lb. copper. A new hoist has been installed at the Oliver shaft. At the Shattuck property on Wednesday, a large body of high-grade oxide and carbonate ore was opened up on the 600 level. Drifts on the 500 and 700 levels are all in ore. Stoping will begin simultaneously in all three levels next week. The Shattuck people will not build a smelter at present but wil continue shipping to the Copper Queen smelter. At the Denn-Arizona the drift is being pushed north and south on the 1,000 level. Outside of the find, about ten days ago, nothing notable has developed. Preparations are being made to start sinking to the 1,200, on which level the drift will be directed toward the Copper Queen property. Little can be said of the progress at the Cochise, except that they are gradually working toward the Copper Queen on the north. It is conceded that they will drift into the extension of the big orebody encountered by the Copper Queen, in the 1,200 level of the Czar shaft. During the early part of the week the diamond-drills of the Warren Development Co. passed through the conglomerate and entered limestone formation. The shaft on the Chicago claim has been sunk to a depth of 60 ft., and machinery has been installed to continue sinking.—— At Tombstone the old water trouble is still occupying the centre of the stage. The company has installed two more new 200-h.p. boilers, making a total of seven 200-h.p. boilers and two smaller ones. With these they expect to take out the water, so that sinking can be continued. Regular shipments are being made from the Toughnut, Silver Thread, and Lucky Cuss shafts. At the mill 30 stamps are dropping and as soon as the water can be controlled, the other 10 will be put to work. The concentrate is still shipped to the smelters at El Paso. The expense of treatment has been reduced from $1.50 to $1 per ton.—— Contrary to all expectations, development work in the Chiricahua district has not opened up ore. The operations have been carried on by the Chiricahua Development Co., and it seems that its methods have resulted in a comedy of errors from start to finish. The consensus of opinion among mining men of this district is, that when the option expires September 10, it ought to step out of the way and let men who understand mining take hold of that property: otherwise a good district will be condemned on account of poor management.—— The old Exposed Reef property in the Huachuca mountains has passed into the hands of the Elwell Mining Co. There was a great deal of friction among the stockholders of the old company, which has happily led to the transfer. This is a gold property and has always given promise of being a mine if properly handled. Stocks in this district have been holding up very well in spite of the summer season.

Bisbee, June 23.

At the Shattuck-Arizona mine at Bisbee, last week, while cutting the station on the 600-ft. level, near the shaft a fine orebody was encountered. Ore has now been found on the Shattuck on the 500, 600 and 700 levels. Most of the development has been done on the 700. The pumps are working night and day, lowering the water in the shaft. At the 800 level drifting will be resumed. Regular shipments to the Copper Queen smelter, at Douglas, over the tramway will be commenced in August, and Shattuck-Arizona will become a steady producer within two years after the development work was begun.

GILA COUNTY.

(Special Correspondence).—Mr. Palmer, president of the Shannon Copper Co., who has been in Clifton the past few weeks, left for his home in New York the first

of the week.—A franchise was granted last week by the board of supervisors of Graham county for the construction and operation of the electric line from Clifton, Morenci and Solomonville, the franchise to run for 99 years. It is the intention of the promoters to construct the Clifton-Morenci line first and then extend it to Solomonville, Safford, Thatcher and other Gila valley towns, in this county. The reduction of freight rates from the Gila valley to the mountain mining towns will surely follow. — The incline of the Shannon Copper Co., at Metcalf, was greatly damaged by fire on Wednesday night, June 13, and at one time the whole structure was seriously threatened. The manner in which the fire started is not known, but it is believed to have been caused by a lighted cigarette dropped by one of the workmen.—The weather has been so dry that the timbers of the structure were like tinder, and the fire had made much headway before it was discovered, burning the hoisting apparatus at the top of the incline. The incline was so badly damaged that no ore can be handled over it for a week or 10 days, and with the exception of a little in the bins, no ore is available for the furnaces at Clifton.—Silas Starrett and Dan McKay have taken the contract to deliver the machinery for the Santa Rosa group at Coronado. The contractors have made a mountain cart, employing in its construction the solid iron wheels taken from the slag pots, and connecting them by 6 by 8 timbers. They expect to get the machinery into position without much trouble, although the road is steep. The Santa Rosa group is the property of the Detroit Copper Mining Co. and the work of development has shown such good results that improved drilling is being installed.

Clifton, June 23.

YAVAPAI COUNTY.

A new strike of gold and copper ore has been made in the Senator mine, in the Hassayampa district 15 miles from Prescott. This strike was made at the end of the adit on the Senator property, now in over 2,800 ft. and run to cross-cut the formation, including the veins worked in the old mine. The new find is a four-foot vein carrying gold and copper assaying $50 per ton.

CALIFORNIA.

AMADOR COUNTY.

In the issue of June 16 a report from Sutter Creek was published to the effect that the Keystone mine, one of the largest and most noted mines of California, had been sold to the Bagdad-Chase Gold Mining Co., of New York. Further inquiry, made since the publication above referred to, elicits the information that the report, though premature in announcement, was nevertheless based on fact. For several months past George W. Myers, of Berkeley, has been negotiating with the prospective buyers for the transfer of the Keystone property, acting for the owner, M. J. McDonald, of San Francisco. The Bagdad-Chase Gold Mining Co. is already largely interested in California, owning the noted mines near Ludlow, at Camp Rochester in San Bernardino county, and operating the Soulsby mine, at Soulsbyville in Tuolumne county. Should the Keystone mine pass to the ownership of this company, it will be more fully equipped and operated in a more vigorous manner than at any time in its history. The Keystone has been worked almost continuously for more than 50 years and is credited with a production exceeding $16,000,000, the greater portion of which has been mined above the 700-level. Below that level the mine is still nearly intact, little having been done beyond development, the operators having long since concluded, that as the upper levels would supply all the ore the mill could handle, it was useless to draw on the reserves at greater depth until it became necessary.

BUTTE COUNTY.

C. L. Wilson, representing a Los Angeles company, is operating a quartz vein on the Pieper ranch, near Forbestown. From a 50-ft. shaft, drifts have been driven on a vein two to six feet wide that shows gold, and is said to sample $50 per ton.—Near Robinson's mills an arastra is being constructed to grind ore from a vein on the Tompkins ranch. The vein is 18 in. to 4 ft. wide and rich in gold.—The McNair mine, owned by L. A. Russell, is near the Tompkins ranch. It has produced several thousand dollars, mostly from pockets.—The Phoenix mine, near Hurleton, which has been idle for some time, is to be reopened, according to local report.—The North Star mine is reported under bond to J. H. Thomas, who intends to operate it. There are several veins in the North Star property, and some of the ore is of good grade.

CALAVERAS COUNTY.

At Mokelumne Hill, J. J. McSorley began prospecting early in June for a quartz vein supposed to exist in French hill, less than a mile from town. McSorley and New York associates recently purchased 40 acres of ground covering French hill, and last week the miners uncovered a vein of quartz two feet thick that will mill $100 per ton.

The overturning of a freight car of a train running on the Sierra railway between Jamestown and Angels on June 26 exploded a ton and a half of dynamite and killed two brakemen, Hoagland and Brown. The car carrying the dynamite jumped the track on a curve, and was completely destroyed, parts of the wheels being thrown a mile and a half. The chlorination works at the Carson Creek mine were wrecked by the explosion, which was felt at Stockton, 60 miles away. The dynamite was for use in the mines at Angels.

KERN COUNTY.

(Special Correspondence.)—The tungsten mine near Randsburg is operating and shipping the ore. At first the tungsten mineral (scheelite) was found only in detached boulders; now the vein from which these fragments come has been found. It is reported here that $27,000 has been paid on the purchase price, which is $100,000, and after paying all expenses, the owners have over $25,000 in the treasury, all from the proceeds of operation.

Randsburg, June 23.

LOS ANGELES COUNTY.

The Lowell & California Mining Co., operating the Big Horn mine on North Baldy mountain in the San Gabriel range, 50 miles northeast of Los Angeles, is to build a 60-stamp mill. This property was first equipped with a two-stamp mill and later ten stamps were put in. The extensive development of ore reserves has made a large increase in milling facilities desirable. There are numerous mineralized zones in the schists of these mountains, but few of them have been developed.

MARIPOSA.

(Special Correspondence.)—The Mount Gaines mine, five miles east of Hornitos, is successfully operating after the various vicissitudes which even good mines sometimes experience. It was first worked about 1895, but in its early history the gold was found much scattered, and it was generally considered a pocket mine in many ways similar to the numerous other pocket mines of the vicinity of Hornitos. There was, however, a good deal of low-grade ore in the vein, which was mined by the operators at that time. As the proposition proved unprofitable, work was discontinued and the mine remained idle until about a year ago, when the water was removed from the workings, and examination showed that the soft, slaty material inclosing the lenses of quartz contained as much gold as the quartz itself, and could be worked at a profit. The mine was formerly equipped with a hoist and 10-stamp mill, which had been removed. Two Huntington mills, each operated by a separate gas engine, and a steam hoist were installed. An examination of the filling, which comprised the slaty material mined by the old management, was made, and it was found that it also contained good pay. The management is now successfully mining a vein 4 to 12 ft. wide, sending everything between the walls to mill; in addition to which some selected high-grade sulphide ore is shipped. The Huntington mills are to be replaced by 20 stamps.—The Exchequer mine, near Merced canyon, eight miles northeast of Hornitos, the old Quartz Mountain mine, two miles south of Hornitos, the Grimshaw, between the Exchequer and Mount Gaines, and the Organita, east of Quartz mountain, are all either working or about to resume. The deepest mine in the district is the Washington, two miles northeast of Hornitos. That mine is 1,500 ft. deep and produced $2,000,000. It has been idle many years.

Hornitos, June 24.

MONO COUNTY.

McCord & Lorendo have completed their one-stamp mill, and will commence crushing ore July 10. Their property is situated on old Mono Diggings, which in the early days of Mono county netted the owners large profits.—The hoisting plant, formerly used on the mining property at Sigourney Flat, just south of Bodie, has been torn down and removed to the Midnight mine bonded by Denver capitalists. Two shifts, including 25 men, are employed in development.

W. B. Searles, engineer of the Bodie Mining Co. is at Sweetwater, Nev., and has begun preliminary work on the erection of an electric station that is to generate electric power for Bodie, Aurora and Masonic. The station is to be built on the east Walker river and will cost over $100,000. Reed Smoot of Salt Lake and J. R. Twelves, of Provo, are interested in the company. The company's heaviest investment is in mines in Bodie and Masonic districts. Several years ago the stockholders purchased several groups at Bodie and afterward took over the Syndicate mine. They will use the adit and other workings of this old company to develop their adjoining claims. There is a large mill and cyaniding plant on the property. The company also took over the Jump-up-Joe mine in the Masonic country, which is now being developed.

SIERRA COUNTY.

Two or three miles from Boca boring for coal is in progress. It is claimed that for the past 30 years it has been known that there were evidences of coal, but it is only recently that boring for it began.—At Washington, the Giant King mine is to be opened. W. L. Williamson has gone to Washington to arrange for starting the lower adit. The mine has been sampled and eastern people are backing the enterprise. The Giant King has probably the largest vein in the county. It varies from 70 to 90 ft. in width and mill tests have returned $4 per ton. The lower adit taps the vein at a depth of 100 ft., and at that point better values have been encountered. Where the new adit will be started the natural slope of the ground is such that a mill can easily be erected.—At Steep Hollow mine, above Nevada City, a company, headed by J. W. Jaquath, has a number of claims through which an ancient river channel is known to extend. To determine its exact length and width, as well as the amount of gold contained in the gravel, the company is arranging to prospect the ground with a drill. Holes will be sunk at regular intervals, and the gravel carefully washed. Adjoining ground is being worked at a profit and it is seen the channel runs into the ground controlled by Jaquath and his associates.

SHASTA COUNTY.

The Brunswick mine, situated near the Trinity county line between Deadwood and French Gulch, was sold last week by Francisco B. Rossi to H. D. Lacey, of New York, for $60,000. Several large veins have been opened up. The new owner will erect a 10-stamp mill on the property and will drive an adit to the ledge 300 ft. lower than the present workings. In the early '80s the Brunswick was worked by the Brunswick Mine & Milling Company.

TRINITY COUNTY.

At the Bonanza King mine 175 men are employed, some building roads, others digging ditches, and a good crew are in the mine. Machinery for the mill is arriving daily. An aerial tramway a mile and a half long is in course of construction. An electric line from the east fork of Trinity river is being built. The mill and all works will be operated by electricity. The property is owned by Treadwell brothers of San Francisco.—The Sykes gravel mine at Trinity Center employs 30 men. There is plenty of water and a large amount of dirt is being moved.—At Snowslide gulch, near Carrville, R. G. Abrams is working a small placer mine. The gravel prospects well and the owner expects good results from the season's run.—The Strode brothers are getting ready to start their mill on the Oro Grande. The long spell of wet weather has made operations late at this mill.—At the Golden Jubilee, on Coffee creek, ten men are taking out ore and the mill is running.—At the Nash gravel mine 15 men are employed. The water supply is good, ground is being moved rapidly and a big clean-up is assured. William Maitland is the superintendent.—At the Dorleska, development work is in progress.—Many other small mines are being worked and much prospecting going on both for quartz and gravel.

TUOLUMNE COUNTY.

The Hunter mill near Buchanan is to run on ore from the Hardtack mine.—At the Spring gulch, south of Carters, the owners are installing a rock breaker, new concentrator and two 3-stamp mills. The concrete foundations for this machinery were built several years ago by H. J. Sisty.—The Keltze mine, situated ten miles north of Soulsbyville, overlooking the Stanislaus canyon, has been bonded by an eastern company. Ten men have been put to work.—Operations have been commenced at the Uncle Sam mine near Arastraville.

COLORADO.

DOLORES COUNTY.

At Rico the Hicks & Mylcram lease on the Smuggler is piling up a good grade of ore preparatory to shipment.—— The Herron & Wold lease on the Yellow Jacket has opened up a fine body of lead-zinc ore.—— Charles Rohde is running a new adit on his Lillie D. claim to cut the orebody.—— Merrifield & Campbell, lessees on the Syndicate, are running their concentrator continuously and making a good grade of concentrate.

LAKE COUNTY.

The Triangle Mining Co., in Leadville district, has secured a long and favorable lease on the Badger, Lady Alice and Triangle claims and some fractions belonging to the Gaff estate, situated on the east side of Adelaide park. Several years ago the owner did considerable work on the Lady Alice and Badger claims, sinking the Badger shaft 900 ft. and the Lady Alice to 300 ft. Numerous drifts were run on both claims and some good

ore found. With the death of the owner work was suspended and the properties have been idle for years. It is the intention of the company to work the Badger shaft alone for the time being. After the shaft is put in proper shape and machinery is installed, exploration will be carried on from the bottom of the shaft to find the orebodies. With the unwatering of the down-town mines, the water problem in Adelaide park, to a great extent, has been solved, so the new company will have no trouble from this source.

In the Twin Lakes district, electric and steam plants are to be installed, and two mills will be built this summer. One is being erected by Harrison, Robinson and others, of Leadville, at the base of Champion mountain, at Lackawanna, in a gulch near the summit of the Continental divide. Notwithstanding the rich ore found in the district, its development has been retarded by high altitude and difficulties of transportation. Better weather conditions have inaugurated an era of activity in this part of the district. Several four-horse teams loaded with a crusher and other machinery went there last week, the old Bromley mill has been purchased and will be moved soon, and another mill was taken in last fall, and these will be combined to make an up-to-date plant.—At the Miller mine the owners have opened up a four-foot vein from which several shipments have been made. Adjoining the Miller, lies the Dick Turpin, from which several thousand tons of float have been shipped. This claim is owned by Tingley S. Wood, of Leadville, and forms a part of his Theodolite group, extending into Half Moon gulch. Several other valuable properties have been located on Champion mountain. The Champion mine has shipped ore that returned $1,500 per ton.—The High FallsMining & Power Co.'s property, the McDonough and Lackawanna Boy claims, covers 3,000 ft. of one of the largest veins in the district. With better roads and mining facilities, this locality can be made a producing camp.

SAN JUAN COUNTY.

(Special Correspondence.)—Work is starting on the Gold Prince mill. Men for putting up the steel work are on the way and machinery is being sent in by the Denver Engineering Works Co. of Denver, who are supplying the material. Work will be pushed as rapidly as possible until completed. This mill was started last summer, but on account of the early snows last fall the railroad was unable to handle the material and work was suspended until this summer. The railroad now extends from Silverton, the terminus of the Denver & Rio Grande, to Animas Forks.

Animas Forks, June 23.

SAN MIGUEL COUNTY.

The Tomboy Mine Co.'s 60-stamp mill is undergoing repairs which will increase its efficiency. The old batteries are being replaced by new ones. While this work is in progress 10 stamps at a time are hung up. Among other improvements is a set of new bumping tables. The coal sheds at the old mill have been torn out and a compressor house is being built on the site to hold the 11-ton Ingersol-Sergeant compressor. The new machine is an addition and will not replace those heretofore in use. It will supply air for machine drills in use throughout the mine. Several of the Huntingtons in the old mill are running on ore from the McCoy lease on the old Tomboy. The company is milling the ore under the terms of the lease. The Huntingtons have always been used in treating ore from the old Tomboy, while stamps are used on ore from the Argentine or new Tomboy.—Since the heavy snow in March the road to Alta has been closed to wagons or pack trains. Since supplies could not be taken in, most of the force was laid off. The snow is still treacherous, and after a few steps upon the crust a man breaks through and goes down to his middle. He struggles out only to repeat the performance a few steps further along. Between 12 and 15 men have been kept on development and some very good ore-bodies have been opened. J. L. Brown, manager of the Alta Leasing Co., operating the mine, states that as soon as the trails are in good condition shipping ore will be packed down the railroad.

S. L. Fulkerson, manager of the Pandora Gold Mining Milling & Development Co., says work on the wire-rope tramway from the portal of the main working adit on the Pandora lease to the upper terminal of the new Smuggler-Union tramway, at the mouth of the Pennsylvania adit, will soon commence. When this system of transportation is established the large quantities of low and medium-grade ore in the bins at the mouth of the adit will be sent down to the Pandora 80-stamp mill. The company recently made a shipment of high-grade ore to a smelter. It is the intention to make regular shipments of high-grade ore. Some ore of this class runs as high as 50 oz. gold and nearly 200 oz. silver per ton. The vein is six to ten feet wide; the greater portion is heavily mineralized. Work in the lower, or French, adit is being prosecuted. At a proper point a raise will be driven to the adit above, 250 ft. The Pandora property is owned by the Smuggler-Union Mining Co., and the operators have a lease for several years.

SUMMIT COUNTY.

(Special Correspondence).—The principal shipping mines of Breckenridge district are keeping teams hauling to the Colorado & Southern Railroad and giving the town a busy aspect. The shipping list includes the Old Union, Wellington, Lucky, Country Boy, Sallie Barber and Bullion King. The mills sending out concentrate are: the Old Union, Lucky, Jessie and Minnie. The Country Boy will also figure in this list shortly.—The Wire Patch mine is showing unusual activity. Mr. Putner has a large force getting the remodeled mill into shape. Two new 60-h.p. boilers are being built in. Thirty men are working constantly and more are to be put into the mine. — The Lucky and Minnie combination is employing a large force in both mines, and work is being done in ore.—The Laurium mine on Mount Baldy, owned by the Blue Flag Gold Mining Co., under managment of Robert Niles, is to be worked on a larger scale and the mill will be enlarged to treat four times its former capacity. This mine has now several thousand tons of ore blocked out.—The owners of the Atlantic mine on North Star mountain, having decided that they were sustaining too large a loss in shipping high-grade gold ore to the smelters, have taken a long lease and option on the milling plants at Montgomery camp at the foot of Hoosier pass on the Alma side of the range, and are getting the mills in order for immediate work. The mill is provided with concentrators and a cyanide plant, and some experimenting will be done to determine the best method of handling the ore. This mine is producing large quantities of ore averaging from 3 to 5 oz. gold per ton and at times makes shipments of 10 to 15-oz. ore.—The Jessie Gold Mines Co.'s 40-stamp mill is working day and night and a big clean-up is expected.—The Reliance dredge in French gulch is credited with a daily clean-up of $1,000, at which rate the company will soon have the dredger paid for and begin the distribution of dividends.—A party of officers and stockholders in the Square Deal Mining & Development Co., operating at Frisco, arrived the latter part of the week and are taking a general look around the camp. The management has started the camp and workings in North Ten Mile canyon and the main adit in Chief mountain is now in 75 ft. A commodious boarding-house, office, bunk-house and blacksmith-shop have been built. The visiting party consisted of Frank E. Wire, president, W. W. Wonser, sercretary, F. N. Giddings, director, and several shareholders.

Breckenridge, June 23.

TELLER COUNTY.

Richard Blanchard, superintendent of the Metallic Gold Mining Co., leasing on the Bill Nye claim on the south slope of Copper mountain, in Cripple Creek district, has made a strike on the 185-ft. level, 100 ft. north and east of the shaft, where he broke into a vein 2½ ft. wide. Assays of the screenings run over $100 per ton. The ore shows free gold and sylvanite.

IDAHO.

LATAH COUNTY.

The discovery of rubies and sapphires, on the McGary ranch near Hendrick, is reported.

NEZ PERCE COUNTY.

Frank T. Barnard describes a vein at Peck, where he inspected the croppings, which attracted much attention several weeks ago. He says the gold occurs in limestone which is about 15 ft. wide. The limestone is pure and can be used as flux for silicious ore at the smelters. Parallel with the lime runs a quartz vein which in places contains gold.

SHOSHONE COUNTY.

According to a reported statement of E. H. Moffitt, manager of the Star Mining Co., the property of which adjoins the Morning mine at Mullan, a compressor for the prospect will probably be in operation by July 1. The adit is in 300 ft. and is being driven by hand at the rate of 65 ft. per month. With the installation of the compressor, hand work will be discontinued and three shifts with machine-drills will supplant the hammers.—It is reported that F. A. Heinze has bought the Stewart mine for $400,000.—A deal has been closed at Mullan whereby A. M. Strode's interest in the Reindeer Copper-Gold Co. has been sold to McRae, Keys, et al. of Mullan. The new owners of the controlling interest have assumed the management. The Reindeer group consists of six claims about three and a half miles east from Mullan not far from the "S" bridge on the Northern Pacific's Coeur d'Alene branch. Development is being rapidly pushed.

WASHINGTON COUNTY.

C. F. Drake, president and general manager of the Hancock Copper Mines Co. near Ladore, says of the Seven Devils district, that there is activity on all sides which will be increased as the season advances. From the Queen mine high-grade ore is being hauled to Council and shipped to the Sumpter smelter.—On the Humboldt property owned by the Hancock Co., Mr. Drake states that the adit is in 400 ft. and is being driven ahead in a body of good grade ore. Ten teams are hauling ore from the mines to Council for shipment to Sumpter. Hauling costs $9 to $11 per ton. It is impossible to procure sufficient teams to supply the demand.

MICHIGAN.

HOUGHTON COUNTY.

The question of disposing of the waste sand, which must eventually be met and solved by every stamp-mill in the Lake Superior region, is to be worked out along new lines by the Mohawk, and as necessity demands by the other Stanton companies. The method to be applied is the invention of J. F. Jackson, who has had it under consideration for some time. It was accepted by the Stanton management only within the last few days. The only stamp-mill at the lake now using mechanical means to dispose of its waste sands is the Calumet & Hecla, where tailing wheels, from 40 to over 60 ft. diam., with buckets in the inner periphery of their rims, elevate the material to their respective heights and discharge it into launders through which it flows by gravity the necessary distance out over former accumulations and into the lake. This method has been used in times past by other mills, particularly the Franklin, which at one time had three stages, or relays, in order to get the sand out a sufficient distance. But because of the removal of all the mills to new places during the last 10 or 15 years, with deeper water and more sand room, the problem has not presented itself recently until now the Mohawk is taking it up. The Atlantic was spared the necessity of taking action by reason of two or three violent storms which washed out a large portion of the sand accumulation into Lake Superior. The Atlantic also discharges its sand from the upper jigs as far as possible at that level instead of permitting them to flow down to the common level of the lower portion of the concentrating floor, and thus it has a longer flow through the launder, which helps materially in adding to the distance which the sands may be carried from the mill by gravity. The new method worked out by Mr. Jackson has as its prime feature of economy the separation of the water from the sand, after which the water will flow by gravity, but at a much flatter incline than when it carries the sand with it. The sand will then be lifted on an endless belt elevator to a hopper directly above the water launder and will be carried then by a belt conveyor that will extend the full length of the water launder and immediately over it. When the end of the launder is reached the mechanically conveyed sand will be discharged into the water just as the latter flows over the lip of the launder and will thus be spread out and diffused in the same manner as if it had been conveyed the entire distance by the water. The elevator and conveyor will be operated by electric motors. In the stamp-mill about 30 tons of water are mixed with every ton of sand, consequently when the entire mixture is elevated, as in a sand wheel, 30 times more weight must be lifted than when the sand alone is elevated. By the new method it is only necessary to elevate the sand a short distance, bringing it just above the water launder. Operating against these economies there is, of course, the cost of conveying the sand mechanically the entire length over the water launder, but it is expected that a material net gain will accrue over the handling of both sand and water mechanically. It is planned to cover the equipment in order that it may be protected against freezing. Exhaust steam pipes will also extend through it for the same purpose.

MONTANA.

MADISON COUNTY.

On June 26 near Virginia City, Dan Carroll, formerly a Butte miner, attempted to thaw 70 sticks of dynamite in a blacksmith forge. Carroll's head and arms were blown off, the body being hurled through the roof of the shop and landing on the slope of a hill 60 ft. away. The blacksmith-shop and machine shop were totally wrecked, the damage being estimated at about $2,000.

NEVADA.

ESMERALDA COUNTY.

It is reported that Mattly & Clayton have struck good rock on their lease. The shaft is down 175 ft. A ledge was cut during the sinking of this shaft, from which an average assay of $300 per ton was taken.

HUMBOLDT COUNTY.

The Lone Mountain Co., owner of the Humboldt Queen, have let a contract for a 200-ft. shaft to be sunk 180 ft. south from the old workings. John Borland has the contract. The shaft will be sunk to strike the body of ore which, by surveys of the lower workings and surface croppings, it is thought will be found.—In the beginning of this work, Mr. Sims, superintendent, is starting extensive improvements on the Humboldt Queen.

LINCOLN COUNTY.

(Special Correspondence.)—Railroad companies are racing in construction across the desert in southern Nevada to reach the traffic offered them. Several years ago building was commenced on a road from Caliente to Pioche but for some reason the project was abandoned and it remained for the San Pedro, Los Angeles & Salt Lake road to see the future of such an enterprise and take up the matter where it had been left off. Surveying and grading is going on and will be followed by the laying of rails.—— Under the direction of the Searchlight Light & Power Co., engineers are surveying the Searchlight streets, followed by workmen making necessary preparations for installing a new electric light and power plant. The work will be completed not later than September 1.—— L. E. Bamberger, of Salt Lake, is visiting Searchlight this week, inspecting mines of the district.—— A rich body of ore has been opened up in the New Year's Gift shaft of the Duplex mine. The superintendent states that it is shipping ore from top to bottom.—— An extra force of men has been put to work on the Searchlight-Diamond property, opening up another vein that has given good 'hornings' from the grass roots across its entire width. This makes the third shaft now being sunk on this property.—— Vigorous exploration of Crescent properties is bringing high-grade ore to light.—— A new gasoline hoist has been installed on the property of the Lucky Dutchman and a large force put to work sinking for the 300-ft. level.—— The 150-ft. shaft of the Nippeno mine is being sunk deeper. Large quantities of good ore have already been taken from the upper levels, and are on the dump awaiting the mill which the company will build as soon as enough water is developed.—— Three shifts are sinking a shaft on the Big Reef property; the samples taken from the vein which they have opened up are said to run from $45 to $200 per ton.—— In El Dorado and Nob Hill districts, the Capitol group, owned by Monoghan & Murphy, of Needles, has been bonded to G. F. Colton, who with his associates will continue development.—— The Philadelphia group, at Nob Hill, has been bonded by the owners to Wisner, Ward & Co., of New York, for $15,000.

Searchlight, June 23.

NYE COUNTY.

The Minnie May No. 1 lease on the south end of the Johnnie Consolidated Gold Mining Co.'s property at Johnnie, has made another strike and ore is being sacked for shipment. Two weeks ago the first rich strike was made.—— The Bullfrog-Johnnie Co. is preparing to open its property, which is situated southwest of the Johnnie Consolidated Gold Mining Co.'s property. Pipe has been ordered for the completion of a new water system in Johnnie which will be laid on arrival.

STOREY COUNTY.

Work has been resumed in all the Gold Hill mines after a shut down beginning just after the San Francisco disaster, and on the Comstock the mines will be opened with their regular working forces on July 1.

WASHOE COUNTY.

(Special Correspondence.)—The Green-Hill Mines Corporation, operating in the White Horse mining district, has let a contract for grading the railroad between Olinghouse and the mill-site on the Truckee river, and work has been commenced. The mill-site is also being graded. The property of this company is being opened up by cross-cut adits, and drifts in ore.—The Slip mill is running on ore from the Renegade mine which has been leased by Joseph Effricks and associates.—The Springfield-Nevada Corporation has resumed work on its property. A contract has been let to drift 500 ft. on the main adit and work has commenced.—Another strike has been made on the property of the Texas-Nevada Co. in the main north drift, on the 100-ft. level, which has been advanced 250 ft. The vein fills the full width of the drift, and is rich, six inches of it assaying $1,000 per ton gold.—The Keystone-Nevada is working an increased force of men. Rich ore is being taken out. Ore-bins are being built and the mill will be in operation before the close of the present year.—The Ohio-Nevada Co. is sinking a shaft on the Standard claim which it recently purchased.—A cross-cut adit on the Belcher property has been advanced 100 ft.—The owners of the Jim Blaine report a rich strike 125 ft. east of the old shaft on this claim.—The Fern-Cliff Co. has prospected its property on White Horse mountain, and will sink a shaft on the vein that runs through the Valley View No. 1 claim.—The shaft on the Mid-West property, in Jones canyon, has been sunk on the Mormon vein, from which rich ore has been sacked.—The adit on the Optimus group of claims has cut five parallel veins in 155 ft., and opened up what seems to be a permanent water supply. This adit will be continued 1,000 ft., cross-cutting the formation, and tapping the water supply in Olinghouse ravine, for milling purposes.—The Wolverine-Nevada Co. has acquired six or more claims, in section 16, and is preparing to develop the property.—The Jessie M. claim has been sold to a company in Columbus, Ohio, for $20,000. This claim was partially developed by the former owners who uncovered a body of rich ore.

Olinghouse, June 21.

Construction of the Wadsworth-Olinghouse railroad has commenced and 85 horses and 50 men are grading the road-bed. This force is to be increased and those in charge say the road will be completed within 90 days. The road will extend from Wadsworth spur at a point near the Monte ranch and extend to the mouth of Olinghouse canyon, where it will connect with the various mines by a system of tramways.—Near the Monte ranch will also be built a 50-stamp mill for the reduction of Olinghouse ore. It is said to be the intention to make this plant one of the largest in the West and bid for the business of Tonopah, Goldfield and other southern camps.

OREGON.

BAKER COUNTY.

(Special Correspondence.)—Two railroads are simultaneously building toward the Copper range in the district east of Baker City. One is approaching from Snake river near Huntington down to the Iron Dike mine at Homestead. The other is coming in from the west, and construction of a road up Catherine creek from Union is under way. Among recent visitors to the Cooper district were W. P. Harlow, E. J. Collins, and R. D. George of the University of Colorado.—It is reported that Cox and Jennings have bonded their property, on Goose Creek, to Los Angeles capitalists.—John E. Searls, of New York, is at his mine in Cornucopia district, situated at the head of Pine creek, near the foot of the Eagle mountains, and 50 miles northeast of Baker City. It is intended to increase the capacity of the plant by adding twenty stamps and a cyanide plant. He has let contracts for separate cottages, to supplant the bunk and boarding-house system, and encourage the permanent location of men with families. Exhaust steam from the boilers will be utilized to heat the cottages; and the company has its own electric lighting plant.—About seven miles northeast of Baker City is the old Flagstaff mine, which for a number of years has been idle. It was owned by a French syndicate. Last week, Emmett Callahan, of Baker City, took over the property for Boston men and deposited in bank the first payment of $25,000.—E. I. Fields, manager of the Baisley Elkhorn mine, is exhibiting ore from that property that assays 20 % copper and $80 gold per ton. There are 100 men employed at this mine.—Not far from the Baisley-Elkhorn, and near to the Nelson placers, a company from Mattoon, Ill., is developing a vein of free-milling gold ore. Much of it is high grade. Contracts have been let for a mill, by A. W. Butler, manager.—On Rock creek, which runs into Powder river valley on the same side of the mountain, with the two properties last mentioned, a prospect was recently sold in Spokane.—At Timber canyon, the company operating there has men running out ore from a four-foot vein, sorting it into two dumps, one averaging $6 and the other about $150 gold per ton.—On the Sumpter side of the range, where most of the gold producers are situated, the mines are running on full time, and several new strikes are reported.

Baker City, June 25.

UTAH.

JUAB COUNTY.

An important strike is reported on the 1,300-ft. level of the Mammoth mine in Tintic district. This ore, which carries sufficient gold to make it high grade, was opened up some time ago upon the 1,600-ft. level and there is now 300 ft. of stoping ground available; although the main shaft is not being deepened at present, another shaft is being put down from the 2,100 level. This shaft, or winze, is now nearing the 2,200-ft. level and it is likely that sinking will be continued until the 2,500-ft. level is reached.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Pearl Consolidated Mining Co. has closed down, the contract having run out and there being no present market for the ore. Samples have been sent to Denver, and if a suitable method can be found, a mill may be built.—The San Poil Gold Mining Co. has leased the upper workings of the San Poil mine to W. M. Crummer, the former superintendent.—A. C. Cook, formerly superintendent at the Mountain Lion mine, is now superintendent of the Anonymous mine, and is making necessary changes. A number of test-pits have been sunk, and ore found below the oxidized zone, which assays well.—The No. 1 adit broke into the vein, when in 65 ft., through the hanging wall. The No. 2 adit is in 265 ft.

Republic, June 20.

STEVENS COUNTY.

(Special Correspondence).—The Napoleon adit is in ore which assays well in gold and copper. The main adit is in over 400 ft. On the 60-ft. level a cross-cut of 120 ft. is all in ore which has been driven on 173 ft. A wagon road will be built between the mine and Kettle river bridge at Orient.—In the First Thought mine, above the adit-level, a chamber has been excavated, and sinking on the orebody will now be started. The aerial tramway at Silverton, in the Cascade mountains, is being removed to this mine. New quarters are being erected for the men, and the old buildings are being renovated.—R. C. Crowell, has taken a bond on the Young America mine, which produces silver, lead and zinc ore.—The Interstate Co., with a group of 20 claims on the southwest slope of Sunset peak, at the head of Nine Mile creek, is getting ready for extensive operations. A vein five feet wide has been stripped and found to carry gold, silver and copper, and 15% lead.—The Dominion Hill Co. has several claims on a contact from which ore has ben extracted that assays $75 to $100 per ton. A great deal of ore has been taken out through an adit which has developed a number of rich stringers. Beyond those stringers is a reef of quartzite, and further in, a body of good ore, which has not yet been fully crossed by the adit. A raise will be put through to the surface for ventilation, and the company will now employ an additional shift.

Orient, June 20.

BRITISH COLUMBIA.

The profits of the Le Roi mine at Rossland for May reached $50,000. This mine has made a profit of from $30,000 to $50,000 for every month of the present year, and Le Roi No. 2 is making larger profits than ever before in its history.—Following are the shipments for the past week: Centre Star, 2,250 tons; Le Roi, 2,790; Le Roi No. 2, 510; Le Roi No. 2 (milled), 600; Crown Point, 120. Total for the week, 6,270 tons, and for the year, 156,049 tons.—The British Columbia Copper Co. has taken up its option on the Oro Denoro mine at Summit camp. This gives the purchasing corporation another claim adjoining its Emma mine. For the last two months the property has been tested by diamond-drills. The company has also taken an option or working bond on the British Columbia mine at Summit which was held by W. T. Hunter of Greenwood. Men have been sent to the mine to pump it out and prepare it for examination and development. The British Columbia mine was the first shipper of importance in this section when the Canadian Pacific railway was completed from the Columbia river to the Boundary, and much of the copper-gold ore was sent to the Trail smelter. More than 100,000 tons of ore were shipped and then the mine was closed down. It is said that the mine has large bodies of ore that can now be shipped profitably, whereas, in the early days, with high freight rates and smelter charges, and low copper prices, they did not pay to take out. Although the smelting plant of the British Columbia Copper Co. is closed, owing to improvements, the affairs of the company are booming. The Mother Lode mine is being developed under rush orders.—A new compressor building is to be erected on the Emma, near Eholt.—The finest piece of ore seen in Greenwood recently is from the Duncan claim, on the West Fork. The Duncan is under bond to a local syndicate which is developing it. It is near the town of Beaverdell, adjoining the Jolly claim.—More than 600,000 tons of ore have been shipped from Boundary mines and reduced at Boundary smelters so far this year. The figures for the week ending June 23 are: To Granby smelter from Granby mines, 17,313 tons; from Emma, 420 tons; from Skylark, 40 tons; to Dominion Copper smelter from Brooklyn-Stemwinder, 3,135 tons; from Rawhide, 396 tons; from Sunset, 726 tons; from Mountain Rose, 40 tons; to Trail smelter from Providence, 30 tons; from Sally, 20 tons.—Total shipments for week, 22,120 tons. Total shipments for year to date, 601,608 tons.—District smelters treated this week as follows: Granby smelter, 18,393 tons; Dominion Copper Co. smelter, 4,497 tons. Total treatment for week, 22,690 tons. Total treatment for year to date, 611,627 tons.

Personals.

Seeley W. Mudd is in New York.

H. E. West is at Torquay, England.

Henry Brantnober is at Topkouk, Alaska.

Theodore J. Hoover is now at Mexico City.

Newton B. Knox has arrived at Yokohama, Japan.

H. G. V. Adler is on his way from London to Canada.

Charles Butters is on his way to London, via New York.

W. J. Adams has gone to Grass Valley on professional business.

J. L. Marks, of Idaho City, Idaho, is at Silverton, Colorado.

Alexander Burrell is visiting Berkeley, from Helena, Montana.

H. C. Callahan has returned to San Francisco from Australia.

W. H. Truett, of Goldfield, is at the Majestic, San Francisco.

Arthur Thacher has left St. Louis to examine mines in Arizona.

Edgar P. Rathbone has returned to London from Johannesburg.

H. W. Robbins, of Los Angeles, is on his way to Japan and China.

John W. Mercer sailed on June 21 from Montreal for a holiday in Europe.

Curtis M. Lindley is going to Tacoma, where he will work at the smelter.

E. R. Faribault will continue his useful geological work in Nova Scotia.

Joseph Thorn is with the Oriental Consolidated Mining Co., in Korea.

D. C. Jackling is now also manager of the Bingham Mines Co., at Bingham.

O. R. Allen has come from Placerville to San Francisco to buy machinery.

A. C. Cook is superintendent of the Anonymous mine at Republic, Washington.

C. L. Lamoreaux, of Los Angeles, is visiting San Francisco for a few days.

Arthur W. Jenks is manager of the Transvaal Copper Co., at Cumpas, in Sonora, Mexico.

L. E. Bamberger, of Salt Lake, has been inspecting mines in Searchlight district, Nevada.

Joseph B. Tomlinson, of Prescott, Arizona, has gone to Vancouver, B. C., on mining business.

W. A. Prichard has closed his offices in London. His address is now Apartado 1060, Mexico City.

H. Mortimer Lamb is in England, recuperating from his recent illness. He will return to Montreal in July.

R. W. Brock, of the Canadian Geological Survey, is making a further geological study of the Rossland district.

C. Henry Thompson, of the firm of Thompson & Gilliam, has returned to Los Angeles from Durango, Mexico.

William A. Heywood has returned to Butte from advisory work with the North American Co., at Fredericktown, Missouri.

Samuel James is at Colorado Springs, having resigned as superintendent of Los Arcos Mining & Smelting Co., Mexico.

F. L. Johnston has gone to Parmalee, Cochise county, Arizona, to build a stamp-mill for the Huachuca Consolidated Mining Co.

W. H. Whiteside, president of the Allis-Chalmers Co., sailed on June 19 from New York to take several weeks of recreation abroad.

Frederick Lyon, manager of the California properties of the United States Smelter, Refining & Mining Co., was in Salt Lake the past week.

Mark L. Requa is visiting Ely, Minnesota, to see the caving system, in the interest of the Nevada Copper Consolidated Co., of Ely, Nevada.

John S. George, manager of Flower & Co., New York, has returned there after a trip to the Snow Storm Hydraulic Co., at Alma, Colorado.

L. C. Graton will have charge of the collection of copper statistics for the United States Geological Survey after January 1. In the meanwhile he will visit the copper districts of the West.

G. W. Myers has returned to Berkeley from a trip through Amador county visiting the mines along the Mother Lode. He leaves early in July for his annual visit to mines in southeast Alaska.

W. A. Lieblein has been appointed manager of the Salt Lake branch of the Power & Mining Machinery Co., of Milwaukee. W. C. McDowell has been appointed to a similar position for this company at El Paso, Texas.

Books Reviewed.

The Business of Contracting, by Ernest McCullough. This is a little volume on the interesting and highly important matter of contracting. It contains many wise and valuable hints to those in charge of large operations, whether the work is being done under contract or not. There are many things in the handling of men which all who are placed in charge should know, and many of these things can be learned from a perusal of this book. The Technical Book Agency, P. O. Box 691, Chicago, Ill., publishers.

Publications Received.

The United States Geological Survey sends: "The Production of Bromine in 1905," by F. J. H. Merrill, and the "Production of the Lithium Minerals in 1905," by E. O. Hovey. Bulletin No. 280 is on "The Rampart Golr Placer Region, Alaska," by L. M. Prindle and Frank L. Hess. Bulletin No. 282, "Oil Fields of the Texas-Louisiana-Gulf Costal Plain," by N. M. Fenneman; Folios No. 136 of St. Mary's, Maryland-Virginia, and No. 137 of Dover, Deleware-Maryland-New Jersey.

The Copper Deposits of the Robinson Mining District, Nevada, by A. C. Lawson, being a Bulletin of the University of California. It describes in detail the interesting ore deposits of Robinson district, more familiarly known as Ely, which within the past three years has come into notable prominence, and which those who know most of the district believe is destined to become an important factor in the copper production of the world. The geology, petrography and genesis of the ore deposits are gone into with painstaking detail, and it is a classical and valuable contribution to mining geology.

Trade Treatises.

The Chicago Tool Co. has issued special circular No. 56 describing their Duntley air-colored electric drills, portable grinders, blowing and drilling stands.

Bulletin 128 of the **B. F. Sturtevant Co.,** of Hyde Park Mass., is descriptive of their economizers, and Bulletin No. 131, describes their horizontal engines with their interchangeable parts. Both bulletins are, as is usual with their publications, handsomely illustrated.

The Hendrie & Bolthoff Mfg. and Supply Co. have just issued a pamphlet describing and illustrating the Dorr classifier, a new device, constructed on entirely original lines. It is claimed to effect an almost perfect separation of sand and slime. This pamphlet will be sent on application.

'Mine-A-Phones,' is the title of a unique folder sent out by the **Stromberg-Carlson Telephone Manufacturing Co.,** of Rochester, New York. It describes and illustrates their mine telephones, which are rapidly coming into favor in mines. Bulletin No. 19, of this company, is a handsomely illustrated catalogue, describing in detail the installation and usefulness of their mine telephones.

Commercial Paragraphs.

The Crocker-Wheeler Co., of Ampere, New Jersey, reports the recent sale to the Wellman-Seaver-Morgan Co. of three 100-h.p. motors.

Woodin & Little have erected a warehouse and store at 534 and 536 Mission St., between First and Second, where they will have a complete stock of pumps for all purposes, for electric motors, gasoline engines, horsepowers, hand and windmills.

G. W. Myers, of **The Chrome Steel Works,** reports having closed negotiations with the Argonaut, Zeila, and Bunker Hill mining companies to supply chrome steel stamp-mill supplies. He also renewed contracts with the Alaska-Treadwell Gold Mining Co. for chrome steel shoes and stamp-mill parts for the fourth consecutive year.

The Power & Mining Machinery Co., of Milwaukee, recently received an order for 12 sets of 36 by 15 in. crushing rolls and two sets of 54 by 20 in. crushing rolls, for the Utah Copper Co., of Garfield, Utah. The 54 by 20 in. rolls will be the largest of their kind ever built, and constitute an advance order for one of four units of crushing rolls to be installed in the above plant. The rolls are being built in accordance with designs made by Mr. Bradley, consulting engineer for the Utah Copper Company.

New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 10 Bacon Block, Oakland, has official reports of the following United States patents issued to Pacific Coast inventors:

Patents Issued June 19, 1906.

823,754.—**Saw Swage and Shaper.**—W. Barkla, Spokane, Wash.

824,061.—**Refrigerator.**—L. Borden, Spokane, Wash.

823,913.—**Protective Gate for Moving Pictures.**—L. Bories, San Francisco, Cal.

823,922.—**Garment Supporter.**—C. Chrysler, Los Angeles, Cal.

823,991.—**Water-Gate.**—A. J. Collar, Yreka, Cal.

823,993.—**Portable Wire Fence.**—J. M. Crawford, Crawford, Ore.

823,594.—**Punching Bag Support.**—J. F. Frazee, San Francisco, Cal.

823,595.—**Ball-Bearing Support for Punching Bags.**—J. F. Frazee, San Francisco, Cal.

823,773.—**Bill Delivery Mechanism for Meters.**—R. W. Gallagher, San Francisco, Cal.

824,076.—**Convertible Furniture.**—D. H. Goodrich, Berkeley, Cal.

824,007.—**Riveting Device.**—W. T. Gordon, Juniper, Ore.

824,009.—**Sawing Machine.**—Gray & Horning, Oakland, Cal.

823,857.—**Grinder for Cultivator, Disks and Tools.**—G. B. Greene, Courtland, Cal.

823,723.—**Perpetual Calendar.**—J. Guidinger, Los Angeles, Cal.

824,012.—**Composition of Plaster.**—Harris & Barrick, Los Angeles, Cal.

824,016.—**Poster and Color Printing.**—C. S. Heermance, San Francisco, Cal.

823,864.—**Steam-Boiler.**—F. J. Hickey, Sacramento, Cal.

823,866.—**Oil Burner.**—W. F. Hogan, San Francisco, Cal.

823,865.—**Parallel Ruler.**—I. M. Hofstad, Wrangel, Alaska.

823,533.—**Electric Light Bracket.**—E. F. Hug, Elgin, Ore.

823,872.—**Earth Cutter and Grader.**—D. W. Jones, Sacramento, Cal.

823,883.—**Rotary Valve for Engines.**—F. T. Leggett, North Yakima, Wash.

823,733.—**Kerosene Incandescent Lamp.**—J. A. Mathes, San Diego, Cal.

823,734.—**Kerosene Vapor-Stove.**—J. A. Mathes, San Diego, Cal.

823,802.—**Friction Set.**—M. B. Miner, Sampson, Ore.

823,625.—**Musical Instrument.**—O. H. Newman, Oracle, Arizona Territory.

823,891.—**Trousers Holder and Presser.**—K. Nishimoto, San Francisco, Cal.

824,081.—**Wrench.**—H. L. Reynolds, Seattle, Wash.

824,082.—**Wrench.**—H. L. Reynolds, Seattle, Wash.

823,973.—**Induction Coil.**—S. H. Sauve, Spokane, Wash.

823,814.—**Portable Wardrobe.**—A. M. Schuff, Wells, Nevada.

824,046.—**Electro-Magnet.**—C. F. A. Sturts, San Francisco, Cal.

A trachymeter (rough measure) is described as a theodolite equipped with devices for measuring both vertical and horizontal angles, and also with an arrangement for measuring distance in the telescope.

HELP WANTED.

COMPETENT MEN wanted in all branches of mining and engineering work for good positions now open throughout the Western States and Old Mexico; superintendents, foremen and managers of mines, mills, cyanide plants, samplers and smelters; also assayers, chemists, engineers, surveyors, draftsmen, mill men, electricians, metallurgists and other technical men. Write for particulars. State age and qualifications. Mining, or Engineering Department, BUSINESS-MEN'S CLEARING HOUSE (Established 1903), 505 to 508 Century Bldg., Denver, Colo.

WANTED, to go with Reynolds Alaska Development Company, honest educated hustler, who can run men in hard rock; some knowledge of electrical machinery advantageous; salary $200. Address R. N. Cummings, 614 Madison St., Seattle.

WANTED—A first-class assayer and chemist. Nevada Goldfield Reduction Co., Columbia, Nevada.

WE KNOW THE MAN YOU WANT

His professional record thoroughly investigated is at your disposal at any time. *Write us.*

The Engineering Agency, Inc.
ALBERT G. FROST, Pres.
Chicago, Ill. Est. 1893. Pittsburg, Pa.

WANTED.

I HAVE TWO PROSPECTS, LOCATED NEAR transportation, and where labor is cheap, in which I will give a substantial interest to reliable parties, who will furnish capital to do a small amount of development work. Let me explain the opportunities that Oaxaca offers. References furnished. Chas. Goldsberry, Ocotlan, Oaxaca, Mexico.

WANTED Information as to available deposits of Magnetic Iron. We are owners of special processes for the separation of magnetic iron from Ores, Sands, Shop Wastes, etc.; and wish to correspond with engineers or owners of properties suitable for operations by dredging, mining and milling, and separation by special machinery.
PUGET SOUND METALS COMPANY,
Pier 14, Seattle, Wash.

Wanted Capital. Copper Property of Great Promise

Own 700 acres; 1100 feet of development work done; need funds to further develop; small amount will prove value of property; to right party a good proposition will be made. Full particulars, including report of expert mining engineer, furnished upon application. Address Box 136, Cedar Rapids, Iowa.

Assay Office in Denver for Sale

for half the cost of outfit. Address Assayer, Box 81, Denver, Colorado.

SITUATIONS WANTED

POSITION as mine superintendent; 20 years' experience underground, in gold, silver and lead mines. Ten years' experience as superintendent and foreman. Expert in handling heavy ground. Age 43 years. First class references. Address Box 66, Mining and Scientific Press.

WANTED, a position with a reliable mining company. Have had technical education and six years' experience mining, milling and cyaniding. References furnished. Address Box 67, this office.

POSITION wanted by a practical, first-class all-around mining, mill and smelter man. Wide experience in Mexico and Arizona. Speaks Spanish fluently and can handle Spanish-speaking labor successfully. Location no object; Spanish-speaking countries preferred, however. Al recommendations. Address Box 68, Mining and Scientific Press.

ASSAYER AND CHEMIST wishes position preferably in Arizona or California. Four years experience in West. Best references. Address Box 70 this office.

WANTED—SITUATION as Arsenic Refiner, or where fumes are damaging animal or vegetable life; 20 years' experience. W. Johns, Morenci, Arizona.

CYANIDE ENGINEER, open for immediate engagement; recently mill superintendent in most complete mill and cyadide plant in the West—stamps, re-grinding mills, tables, tube mill, vanners, slimers, sands and slimes plants. This latter is the system devised by Mr. Chas. Butters and is making an extraction of over 96 per cent from slimes worth $20. Have had twelve years' experience with various companies as assayer, amalgamator, cyanide man, master mechanic, foreman and superintendent. Have erected Blaisdell's system of sand excavation. Speak Spanish and accustomed to Mexican ways. Experienced with electro-precipitation for silver ores, and in working out processes for stubborn ores. University of California; 33 years; sober, married. Best of references. Address Box 69, Mining and Scientific Press.

JOB wanted as working superintendent, or foreman of mine. Experienced and thorough. Accustomed to alkali water and a strenuous life. Address Taurus Silex, care of Mining and Scientific Press office, Berkeley, Cal.

MINE superintendent; 12 years' all-around mining; experience in Montana and British Columbia; first-class reference. Surveyor and Assayer. Box 71, this office.

EXPERIENCED cyanide man desires position. Can design and erect mills. Practical chemist and assayer. Graduate of University of California. Address "Cyanide," Box 790, Goldfield, Nev.

COLUMBIA graduate, 1 year's experience, wants position in mining, milling, machinery, engineering, assaying, or as foreman or shift boss. Experience more an object than salary. Address "Mining," care this office.

IT will pay you and pay you well to secure your men through the "Clearing House" system. It saves you valuable time, much troublesome work, and affords you a choice of men from among the best throughout the United States. We are supplying the largest and most prominent mining and engineering companies throughout the Western States and Mexico. Send for our new booklet, "Competent Men for Western Employers." Address Mining, or Engineering Department, BUSINESS-MEN'S CLEARING HOUSE (Established 1903), 505 to 508 Century Bldg., Denver, Colo.
